FIG. **1**(A) is a perspective view of a sealing device of the present invention before the attachment to a slider; FIG. **1**(B) is a plan view of a punched plate according to the present invention; FIG. **2**(A) is a front sectional view showing the sealing device of the present invention; FIG. **2**(B) shows a second rolling member rolling groove according to the present invention and is a sectional view taken along the line 2(B)—2(B) in FIG. **3**; FIG. **3** is a front view, partially cut away, of the sealing device of a linearly movable mechanism according to the present invention; FIG. **4**(A) is a front view, partially cut away, of a sealing device of a linearly movable mechanism of a conventional structure; FIG. **4**(B) is a perspective view of FIG. **4**(A); and FIG. **4**(C) is a perspective view of an end seal secured to an end plate of a conventional structure.

BEST MODES FOR EMBODYING THE INVENTION

The present invention will be described hereunder with reference to the accompanying drawings. FIGS. **2**(A), **2**(B), and **3** show a guide mechanism of a linear motion to which the present invention is applied. In these figures, reference numeral **1** denotes a guide rail having a predetermined axial length, and the guide rail **1**, and two rows of first rolling member rolling grooves **3** are formed to both side surfaces **2** of the guide rail **1** in a vertically aligned attitude in the illustration, each of the first rolling grooves **3** having an arcuate cross section and extending in the axial direction of the guide rail **1**. A plurality of attachment holes **6** are formed to the central portion in the widthwise direction of the guide rail **1** with predetermined spaces therebetween in the axial direction thereof for inserting bolts, not shown, from the upper surface side **4** to the lower surface side **5**. The upper surface **4** of the guide rail **1** is formed to be flat.

A slider **7** having substantially a]-shaped cross section is mounted on the guide rail **1**. The inner side surfaces **8** of the]-shaped slider **7** face the side surfaces of the guide rail **1** and two rows of second rolling member rolling grooves **9** are formed to both the inner surfaces **8** of the sides of the slider **7** so as to extend in the axial direction thereof. End plates **10** each having a sectional shape substantially similar to that of the slider **7** are attached to both the axial end surfaces of the slider **7**.

Each of the second rolling grooves **9** is formed circularly through the insides of the slider **7** and the end plate **10**, and a number of balls **11** (such as steel balls) as the rolling members are disposed between the second rolling grooves **9** and the first rolling grooves **3**. According to the structure described above, the slider **7** is movable on the guide rail **1** along the axial direction thereof.

A sealing device M shown in FIG. **1**(A) is attached to the slider **7**, the sealing device M being described hereunder. Reference numeral **50** is a plate body made of a metal material, for example, which is composed of a pair of end plates **51** to be attached perpendicularly to both the ends of the end plate **10**, each of the end plates **51** having a]-shaped section and a horizontal connection plate **15** connecting]-shaped recesses **52** of both the end plates **51** at its both axial ends. End seals as first sealing members **16** made of a rubber-like elastic material (nitrile rubber, styrene rubber, butyl rubber, or the like) are bonded to the surfaces of the paired end plates **51** such as sintering manner. The end seals **16** serve to seal a space between the slider **7** and the upper surface **4** of the guide rail **1** and the inner peripheral surface of each of the end seals **16** has a shape similar to the outer peripheral surface of the guide rail **1**. The end seals **16** are formed on the entire surfaces of the end plates **51**, but they may be applied locally only on the surfaces of the recesses **52**. Screw insertion holes **54** and insertion holes **60** for grease nipples **21** are formed to the end plates **51** at portions opposing to each other, respectively.

The connection plate **15** has a cross sectional shape as shown in FIG. **2**(A) and is composed of a base portion **22** having a width of a size more than an opening diameter of the attachment hole **6** and bent portions **23** formed by bending downward both edge portions of the base portion **22**. A pair of inner seals **24** as second sealing members are bonded such as in sintering manner to the outside surfaces of the bent portions **23**. The inner seals **24** are formed of a rubber-like elastic material (nitlie rubber, styrene rubber, butyl rubber, or the like), and are provided with lip portions **25** at the lower end portions, as viewed, thereof so as to face each other, that is, to incline towards the attachment hole **6**. The lip portions **25** contact the upper surface **4** of the guide rail **1** in the axial direction thereof with a predetermined contacting pressure with respect to the space between the attachment hole **6** and the first rolling grooves **3**, thus forming a sealing surface.

The sealing device M will be manufactured in a manner described hereunder with reference to FIG. **1**(B).

The plate body **50** is first formed from a plate member by means of a pressing machine, not shown, so as to have a pair of end plates **51** and the connection plate **15** integrally formed to the end plates **51** so that the end plates **51** are positioned at both the axial ends of the connection plate **15**. The thus formed plate body **50** is placed in a cavity of a mold, not shown, and a rubber formation material is then fed into the cavity. The end seals **16** are sintered or baked on portions near the recesses **52** of the end plates **51** and the inner seals **24** are also sintered or baked to the bent portions **23** of the connection plate **15** along the axial direction thereof. Thereafter, the plate body **50** is separated from the mold and the plate body **50** is bent along folding lines **55** and **56**, thus completing the sealing device.

Furthermore, a passage **20** for supplying a lubricant is formed to the slider **7** so as to communicate with a space between the inner lower surface **19** of the slider **7** and the upper surface **4** of the guide rail **1**, and the passage **20** is also communicated with the grease nipples **21** connected to the end surface sides of the end seals **16**.

A plate **12** for holding the balls **11** is provided for the inside surface **8** of the slider **7** and the plate **12** is fastened to the lower surface of the slider **7** by means of bolts **13**.

The slider of the structure described above is assembled with the sealing device M in the following manner.

The end plates **10** are closely contacted to the corresponding surfaces of the end plates **51** and then placed on the connection plate **15**, and thereafter, the plate body **50** is assembled with the slider **7** from the lower side thereof and screws **57** are inserted into the insertion holes **54** and fastened thereto, thus completing the assembling working. In this assembling, the formation of femail threads on both the end surfaces of the slider **7** is a matter of natural. According to the present invention, the end seals **16** and the inner seals **24** are together secured to the slider at one assembling working, thus improving the workability and enhancing the productivity of the linearly movable mechanisms.

The sealing device M operates as follows.

The slider **7** can be freely slidable in a linearly reciprocal manner on the guide rail **1** along the axial direction thereof through the rolling motion of the balls **11** disposed between the first and second rolling grooves. Then, the end seals **16** slidably contact the upper surface **4** of the guide rail **1** and the both the side surfaces **2** thereof to construct the first sealing surface, and the inner seals **24** slidably contact the upper surface **4** of the guide rail **1** to form the second sealing surface between them and the end seals **16**. Accordingly, the invasion of the cut chips or foreign materials such as spatters into the space between the upper surface **4** of the guide rail **1** and the inner lower surface **19** of the slider **7** and the space between the side surfaces **2** of the guide rail **1** and the inner side surfaces **8** of the slider **7**, that is, the invasion into the first and second rolling grooves **3** and **9**, can be prevented. Furthermore, even if such chips or foreign materials be invaded thereinto through the space between the upper surface **4** of the guide rail **1** and the inner lower surface **19** of the slider, the chips or foreign materials can be prevented from invading into the first and second rolling grooves **3** and **9** by the presence of the second sealing surface formed between the inner seals **24** and the upper surface **4** of the guide rail **1**. Accordingly, the preferred ball rolling condition can be achieved, thus performing the stable linear motion of the slider **7**. Furthermore, since the inner seals **24** are slidably contacted to the upper surface **4** of the guide rail **1** in the axial direction, the sliding resistance with respect to the upper surface **4** of the guide rail **1** can be made small, thus being difficult to cause wearing thereof.

During the operation described above, the lubrication oil, i.e. grease, fed from the grease nipple **21** is fed into a portion **90** between the slider **7** and the guide rail **1** through the supply passage **20** as arrowed in FIG. 2A. In this operation, since the inner seals **24** contact to the upper surface **4** of the guide rail **1**, the displacement of the grease to the central portion of the upper surface **4** can be limited. Accordingly, the grease fed into the portion **90** can be effectively fed towards the first and second ball rolling grooves **3** and **9** from the outside of the upper surface **4** of the guide rail **1**, thus the sliding surface being well lubricated. Furthermore, the lip portions **25** of the inner seals **24** are inclined towards the central side of the upper surface **4**, so that the used and degraded grease lifts up the lip portions **25** and is removed to the central side of the upper surface **4**. However, when a pressure is applied to the lip portions **25** from the central side of the upper surface **4** of the guide rail **1**, the surface contacting pressure further increases, thus improving the sealing effect.

In the described embodiment, the balls are referred to as the rolling members, but other rolling members such as rollers may be utilized.

Field of Industrial Usage

As described above, the sealing device of the present invention can be utilized for linearly movable mechanisms for machine tools, measuring devices, medical equipments and the like.

Particularly, since the first and second sealing members are together fixed to the slider through one assembling working only by attaching the plate body to the slider, the present invention is applicable particularly for the assembling working to the linearly movable guide mechanisms.

I claim:

1. A linear motion slide unit comprising:

a guide rail in which a first rolling member rolling groove extending in an axial direction is formed;

a slider in which a second rolling member rolling groove facing the first rolling member rolling groove is formed;

a number of rolling members disposed between the first and second rolling member rolling grooves to thereby axially movably support the slider on the guide rail; and

a sealing device comprising a pair of end plates axially disposed at both ends of the slider, a connection plate disposed between the slider and the guide rail in the axial direction thereof and integrally connected to the paired end plates, first sealing members disposed at positions at which the end plates face the guide rail and second sealing members extending along the axial direction of the connection plate.

2. A linear motion slide unit according to claim **1**, wherein said slider has substantially a]-shaped cross section and said end plates have substantially]-shaped cross sections, respectively, to provide recessed portions, said recessed portions of said end plates being connected integrally through the connection plate.

3. A linear motion slide unit according to claim **1**, wherein said first sealing members each has a shape similar to an outer peripheral shape of the guide rail.

4. A linear motion slide unit according to claim **1**, wherein said connection plate comprises a base portion and bent portions formed by bending both edge portions of the base portion and said second sealing members are fixed to outer side surfaces of the bend portions.

5. A linear motion slide unit according to claim **1**, wherein said second sealing members are formed by lip portions inclined towards a central side of the guide rail.

Fig.3

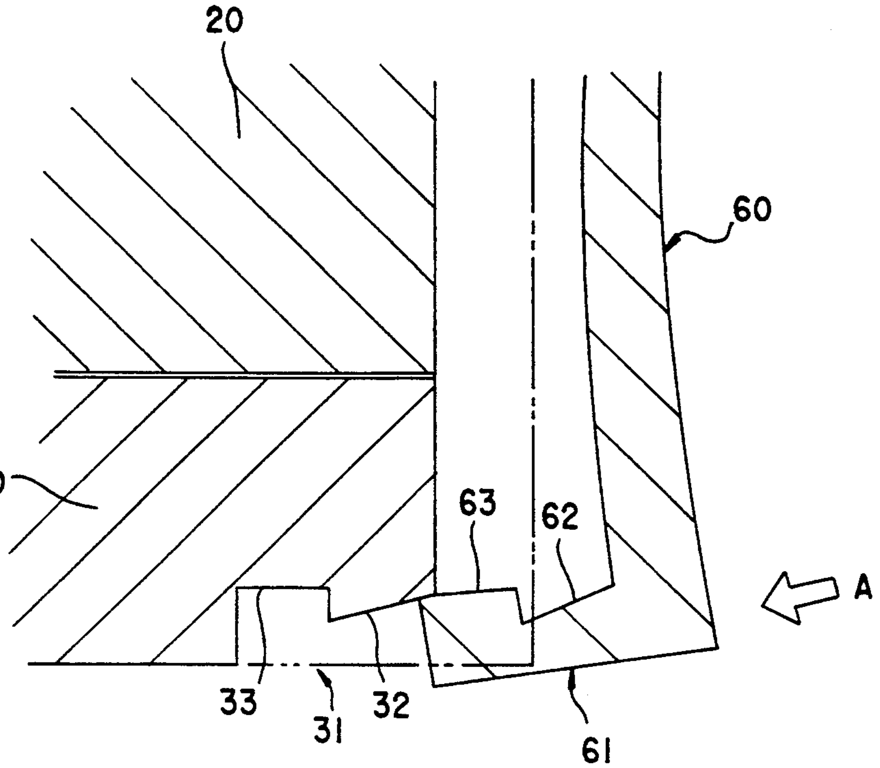

Fig.4

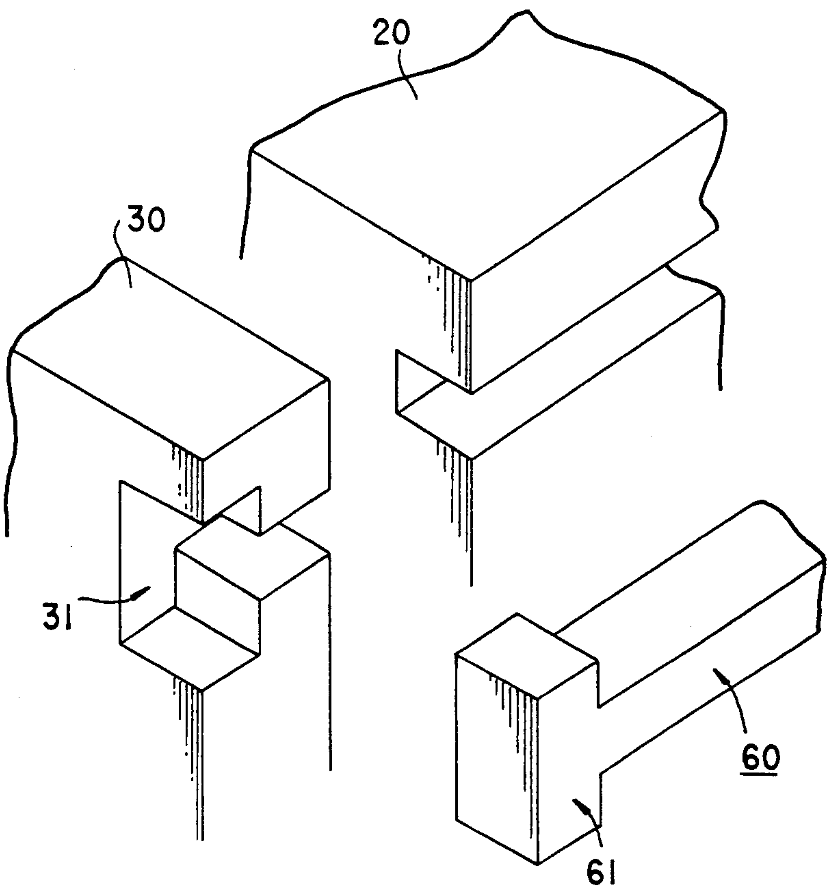

Fig.5

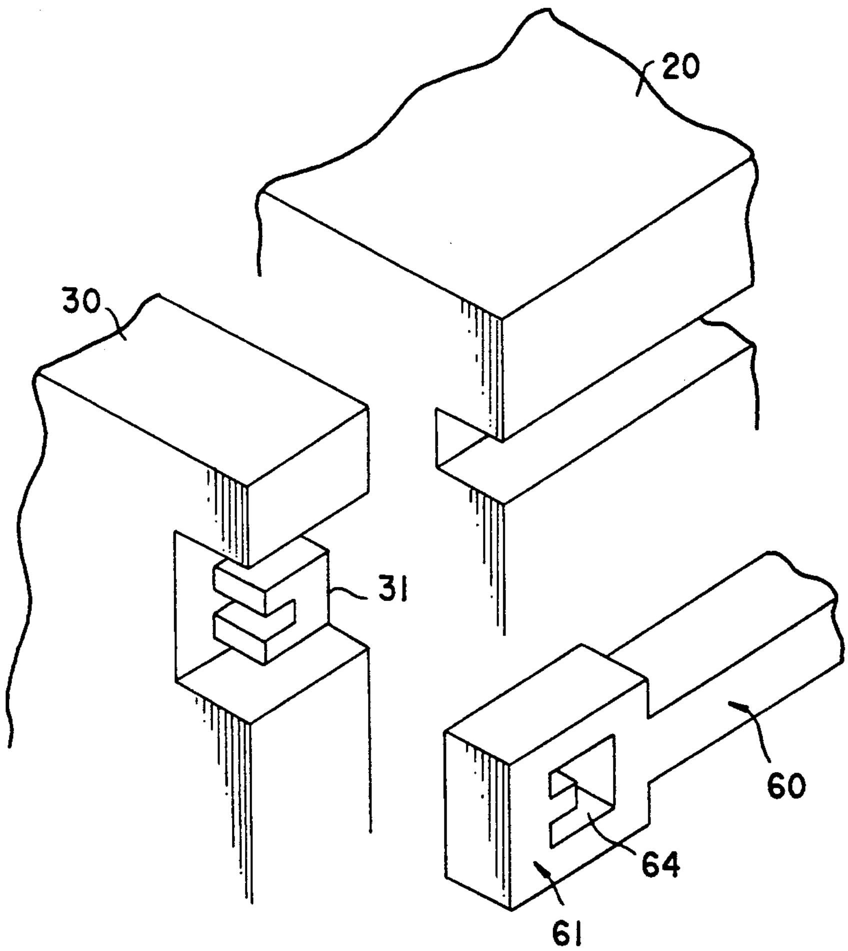

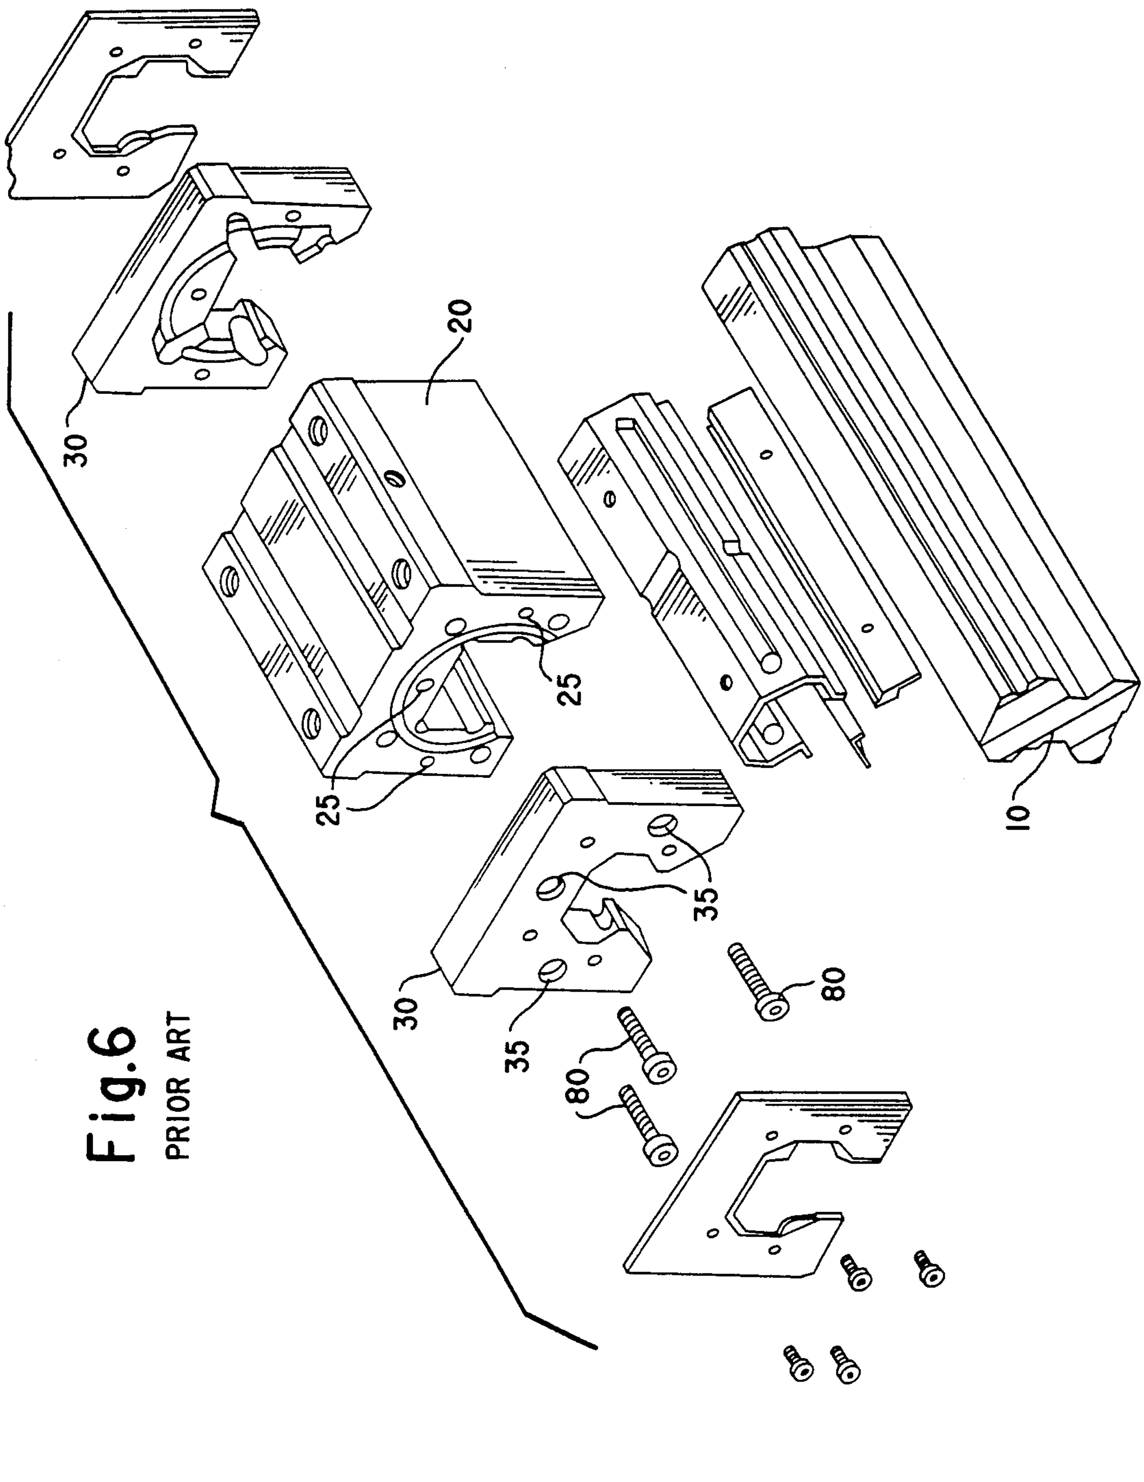

Fig.6
PRIOR ART

SIDE COVER FIXING STRUCTURE FOR LINEAR MOTION BEARING

TECHNICAL FIELD

The present invention relates to a side cover fixing structure in a linear motion bearing for fixing side covers on the bearing body.

BACKGROUND ART

The linear motion bearing is widely used as industrial machine elements such as a table saddle for a machine tool, a slide face of a machining center or a carriage of a conveyor.

The linear motion bearing of the prior art is constructed, as shown in FIG. **6**, to include: a track bed **10**; a bearing body **20** of a metal placed on the track bed **10**; a pair of side covers **30** and **30** of a synthetic resin fixed in abutment on the two end faces of the bearing body **20**; a number of balls **40** interposed between the bearing body **20** and the track bed **10**; and a not-shown retainer for preventing the balls **40** from coming out when the bearing body **20** is removed from the track bed **10**.

In the linear motion bearing thus constructed, the side covers **30** are fixed by using screws **80** on the two end faces of the bearing body **20**. Specifically, the side covers **30** of synthetic resin are formed with through holes **35** in their predetermined positions. Moreover, the metallic bearing body **20** is formed with tapped holes **25** in its corresponding positions. The screws are extended through the through holes **35** of the side covers **30** and fastened in the tapped holes **25** of the bearing body **20**.

In recent years, the linear motion bearing described above is used in OA equipment or electric appliances, too. In these examples of use, the linear motion bearing is generally small-sized and compact.

The tapping operations of the holes **25** in the bearing body **20** becomes the more difficult together with the screw fastening operations as the linear motion bearing has the smaller size.

An object of the present invention is to solve the aforementioned problems of the prior art and to provide a side cover fixing structure capable of fixing the side covers simply and inexpensively on the body of a small-sized linear motion bearing.

DISCLOSURE OF THE INVENTION

According to the present invention, there is provided a side cover fixing structure for a linear motion bearing, which structure comprises: a bearing body; a pair of side covers to be fixed in abutment on the two end faces of said bearing body and each having at least two retaining portions; and at least two connecting plates of an elastic member each having at its two ends hook portions to be retained by the retaining portions of said side covers, whereby said connecting plates fix said bearing body and said paired side covers integrally by having their two end hook portions retained by the corresponding retaining portions of said side covers.

In this technical means, the paired side covers are arranged in abutment against the two end faces of the bearing body. Each side cover is equipped with retaining portions in at least two portions, e.g., at the two side portions. Moreover, the connecting plates made of an elastic member have their two end hook portions so fitted on the retaining portions of the paired side covers as to cross the bearing body. As a result, the paired side covers are fixed on the two end faces of the bearing body by using at least two connecting plates.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is an exploded perspective view showing one embodiment of a linear motion bearing having a side cover fixing structure according to the present invention;

FIG. **2** is a perspective view showing the side cover fixing structure of FIG. **1** when the same is assembled;

FIG. **3** is a section showing a portion of the side cover fixing structure of FIG. **1** and taken along line III—III;

FIG. **4** is an exploded perspective view showing an essential portion of another embodiment of the side cover fixing structure according to the present invention;

FIG. **5** is an exploded perspective view showing an essential portion of still another embodiment of the side cover fixing structure according to the present invention; and

FIG. **6** is a perspective view showing the side cover fixing structure of the linear motion bearing of the prior art.

BEST MODE FOR CARRYING OUT THE INVENTION

A side cover fixing structure of a linear motion bearing according to the present invention will be described in detail in the following with reference to the accompanying drawings.

With reference to FIGS. **1** and **2**, there is shown one embodiment of the side cover fixing structure of the linear motion bearing according to the present invention.

The linear motion bearing, as shown, is basically constructed of components similar to those of the linear motion bearing of the prior art shown in FIG. **6**. Specifically, the linear motion bearing is constructed to include: a track bed **10**; a bearing body **20** of a metal placed on the track bed; a pair of side covers **30** of die cast metal or synthetic resin fixed in abutment on the two end faces of the bearing body **20**; a multiplicity of balls **40** interposed between the bearing body **20** and the track bed **10**; and sealed retainer holders **50** for preventing any invasion of foreign substances. These are components well known in the art, and their detailed description will be omitted. p

The present invention is characterized in that the paired side covers **30** and **30** are fixed in abutment on the two end faces of the bearing body **20**.

In the embodiment of FIGS. **1** and **2**, each side cover **30** is formed at its two end portions with retaining portions **31**. Each of these retaining portions **31** is formed of a slope **32** and a deeper recess **33**, as shown in FIG. **3**.

The side cover fixing structure according to the present invention further includes two connecting plates **60** and **60** made of an elastic member such as synthetic resin. Each of these connecting plates **60** is formed at its two ends with a hook portion **61** to be retained by the retaining portion **31** of the side cover **30**. As shown in FIG. **3**, the hook portion **61** is formed of a recess **62** and a flat face 63, which mate with the slope 32 and the recess 33 of the retaining portion 31, respectively. The recess 62 may preferably have its bottom face inclined at such an angle that it contacts in a face-to-face relation with the slope 32 of the retaining portion 31. As a result, the side covers 30 and 30 are firmly fixed on the two end faces of the bearing body 20.

Since the side cover 30 is formed with the slopes 32, as described above, the hook portions 61 of the connecting plates 60 are opened, as shown, if pushed from the side faces of the linear motion bearing, until they fitted on the retaining portions 31 formed on the two side portions of the side covers 30. As a result, the hook portions 61 of the connecting plates 60 can be prevented from coming out of the retaining portions 31 of the side covers 30.

Incidentally, the metallic bearing body 20 may preferably be formed, as in the shown embodiment, with grooves 21 for accommodating the step portions 64 of the connecting plates. Generally speaking, the bearing body 20 is manufactured by the cold drawing process so that the formation of the grooves 21 extending in the axial direction of the bearing body 20 will not lead to a rise in the production cost. Since the connecting plates 60 are fitted as a whole in the side faces of the bearing body 20, there are obtained advantages that the connecting plates 60 can be prevented from coming out even with the possible contacts with foreign substances and that the bearing body 20 can have its side faces retaining their roles as reference faces.

FIG. 4 shows another embodiment of the side cover fixing structure according to the present invention. In this embodiment, each connecting plate 60 has a T-shaped hook portions 61 whereas the side cover 30 has its retaining portions 31 recessed to fit the hook portions 61.

According to the present embodiment, the T-shaped hook portions 61 formed at the connecting plate 60 are fixedly fitted in the recesses of the side covers 30 so that the connecting plates 60 can be prevented from coming out.

FIG. 5 shows still another embodiment of the side cover fixing structure according to the present invention. In this embodiment, each connecting plate 60 is formed in its hook portions 61 with C-shaped recesses whereas the side cover 30 has its retaining portions 31 formed into projections which are fitted in the recess of the connecting plate 60.

In the present embodiment, the retaining portions 31 and the hook portions 61 are caused to engage in more portions than those of FIG. 4 so that the connecting plates 60 can be firmly fixed in the side covers 30.

The retaining portions 31 of the side covers 30 and the hook portions 61 of the connecting plates 60 should not be limited to those of the foregoing embodiments but could adopt various constructions. Moreover, the numbers and positions of the retaining portions 31 formed at the side covers 30 and the connecting plates 60 can be suitably selected, if necessary.

Next, the method of assembling the side cover fixing structure according to the present invention will be described in the following.

First of all, the paired side covers 30 and 30 are applied to and arranged on the two end faces of the bearing body 20. Next, one hook portion 61 of the first connecting plate 60 is retained by the retaining portion of one side cover 30. After this, the other hook portion 61 of the connecting plate 60 is retained by the retaining portion 31 of the other side cover 30. These operations are accomplished by pushing the other hook portion 61 of the connecting plate 60 strongly in the direction of arrow A, as shown in FIG. 3. Similar operations are carried out for the second connecting plate 60, thus fixing the paired side covers 30 and 30 on the two end faces of the bearing body 20.

INDUSTRIAL APPLICABILITY

As has been described hereinbefore, according to the side cover fixing structure of the present invention, the paired side covers are fixed on the two end faces of the bearing body by using the paired connecting plates so that the linear motion bearing can be advantageously practiced simply and inexpensively even it is small-sized. As a result, it is possible to automate the assembly of the small-sized linear motion bearing and to manufacture a more compact linear motion bearing than that of the prior art.

I claim:

1. A side cover fixing structure for a linear motion bearing, comprising:
   - a bearing body;
   - a pair of side covers to be fixed in abutment on the two end faces of said bearing body and each having at least two retaining portions; and
   - at least two connecting plates of an elastic member each having at its two ends hook portions to be retained by the retaining portions of said side covers, whereby said connecting plates fix said bearing body and said paired side covers integrally by having their two end hook portions retained by the corresponding retaining portions of said side covers.

2. A side cover fixing structure for a linear motion bearing according to claim (1), wherein each of the retaining portions of said side covers is formed of a slope and a deeper recess whereas said connecting plates have their hook portions shaped to mate the retaining portions of said side covers.

3. A side cover fixing structure for a linear motion bearing according to claim (1), wherein said connecting plates have their hook portions formed to have a shape of letter "T" whereas said side covers have their retaining portions are formed with recess for retaining the hook portions of said connecting plates.

4. A side cover fixing structure for a linear motion bearing according to claim (1), wherein said connecting plates have their hook portions formed to have C-shaped recesses whereas said side covers have their retaining portions formed into protrusions to be fitted in the recesses of said connecting plates. j

[57] **ABSTRACT**

According to a bearing and a table for linear sliding motion according to the invention, a sliding table is formed of a plurality of divided blocks which are aligned in one row and have load rolling surfaces on which rolling members rolls. By arbitrarily choosing a number of the divided blocks, a number of the load rolling members can be facilely increased depending on a size of the table to be linearly guided. Therefore, waving of the slide members can be minimized, and linearity of the movement thereof can be improved.

BEARING AND A TABLE FOR LINEAR SLIDING MOTION

TECHNICAL FIELD

The present invention relates a bearing and a table for linear sliding motion for linearly guiding a movable object to be slid, for example, in a slide component for machine tools such N.C. machines or industrial robots.

BACKGROUND ART

A conventional bearing for linear sliding motion of a type described above generally has a construction shown in FIG. 17. Specifically, it is formed of a track bed (or track member) (b) having rolling surfaces (b1) on which rolling members (a) such as balls roll in an axial direction; a slide bed (or slide member) (c) having load rolling surfaces (c1), which cooperate with the rolling surfaces (b1) to hold the rolling members (a) therebetween, and no-load rolling apertures (c2) corresponding to the load rolling surfaces (c1); and covers (d) for coupling and connecting the load rolling surfaces (c1) and the no-load rolling apertures (c2) to form endless paths for the rolling members (a). In this construction, the rolling member (a) rolls through load regions between the rolling surfaces b1 of the track member (b) and the load rolling surfaces (c1) of the slide member (c), whereby the slide bed (c) can linearly move along the track member (b) with a remarkably small frictional resistance.

A table for linear sliding motion, which supports a machine tool or a work for guiding them, generally has a construction shown in FIGS. 18 and 19, in which a plurality of track members (b) (two in the Figure) used for the bearings for the linear sliding motion are disposed on a fixing portion (e), and a plurality of sliding members (c) (two in the Figure) for carrying a table (f) are assembled to each track bed with a space between one another.

However, such bearings for the linear sliding motion have following disadvantages with respect to the motion of the slide members due to its construction.

First, minute vibration called as "waving" is generated in the slide members. In the bearing for the linear sliding motion including the rolling members which circulate and perform an endless movement for the slide member, the rolling members are generally in preloaded conditions when they roll through a load region in order to increase rigidity of the slide member with respect to the track member and prevent rattling thereof. Therefore, when the rolling members are forcedly entered into the load region or released from the load region, the slide member minutely deviates in vertical or lateral directions, which causes the minute vibration, i.e., waving during the movement of the slide member.

A second disadvantage relates to a linearity of a motion of the slide member. It is ideal for the slide bed to move linearly with respect to the fixing portion on which the track member is disposed. However, the motion thereof is inevitably affected by a mounting accuracy of the track member to the fixing portion and a machining accuracy of the rolling surfaces, and thus it is very difficult in practice to obtain a high linearity of the movement. If it is attempted to obtain the desired linearity of the movement by increasing the mounting accuracy of the track member and the machining accuracy of the rolling surfaces, disadvantages such as high costs and low productive efficiency will be caused. Therefore, in view of the above, the linearity of the movement can be improved only to a restricted extent.

The disadvantages of the motion of the slide member described above form an important factor which cannot be overlooked in machine tools or the like which are guided by the bearings for the linear motion during machining operations, because the waving of the slide members or the insufficient linearity of the movement causes deviation of the tools of the machine tools, and thus directly affects the machining accuracy of the products.

However, in the recent industrial application, demands for higher accuracies in various products, and thus demands for higher machining accuracies have been increased in the machines and apparatuses such as machine tools for machining these products.

Accordingly, the bearings for the linear sliding motion for performing linear guiding in various machines and apparatuses have been required to prevent the waving during movement or travelling of the slide beds and to improve the linearity of the movement.

On the other hand, with respect to the tables for the linear sliding motion, reduction of costs has been attempted by minimizing thicknesses of tables which are mounted on the slide members in the recent years. However, this adversely affects the rigidity, and specifically, this may cause deflection or the like in the tables which may reduce the machining accuracies of machine tools mounted thereon.

In view of the above demands and problems, it is an object of the invention to provide a bearing for linear sliding motion, which can minimize the waving of the slide member and improve the linearity of the movement.

Another object of the invention is to provide a table for linear sliding motion which allows machining with a high accuracy by a machine or apparatus such as a machine tool mounted thereon.

DISCLOSURE OF THE INVENTION

The inventor of the invention and others have earnestly studied to achieve the objects described above, and found that, as a number of rolling members which roll through a load region increases, a waving value of a slide bed decreases and also a linearity of a movement is improved. Based on this, with respect to a table for linearly sliding motion, a slide member having a length which is increased to a maximum allowable extent and corresponds to a size of a table for linear sliding motion may be manufactured and attached to a lower surface of the table, whereby the table for the linear sliding motion can have the waving value and linearity for the movement which are improved as compared with the prior art.

However, since tables have various sizes depending on machines and apparatus mounted thereon, it is not preferable, in view of productive efficiency, to manufacture slide members of various sizes in accordance with user's orders.

In view of this, the inventors and others have further studied and devised the present invention.

A bearing for linear sliding motion of the invention comprises a track bed provided with rolling surfaces for rolling members such as balls or rollers extending in a lengthwise direction; a slide member formed of a plurality of divided blocks which are provided with load rolling surfaces cooperating with the rolling surfaces to hold the rolling members therebetween, said divided blocks being joined together to continuously connect the load rolling surfaces; and rolling member circulating means which connects opposite ends of the continuously connected load rolling surfaces to form an endless circulation path for the rolling members.

A table for linear sliding motion of the invention comprises a track member provided with rolling surfaces for rolling members such as balls or rollers extending in a lengthwise direction; a slide member formed of a plurality of divided blocks which are provided with load rolling surfaces cooperating with the rolling surfaces to hold the rolling members therebetween, said divided blocks being joined together to continuously connect the load rolling surfaces; rolling member circulating means which connects opposite ends of the continuously connected load rolling surfaces to form an endless circulation path for the rolling members; and table for mounting a movable member to be guided linearly, said table being fixed to the slide member for movement in a lengthwise direction of the track member.

According to the subject of the invention, in which the slide is formed of divided blocks having the load rolling surfaces and jointed together, a number of the divided blocks may be appropriately varied, and for example, may be determined in accordance with sizes of the table to be linearly guided.

Further, the divided blocks may be varied with respect to a configuration, a number of the load rolling surfaces and a contact angle of the rolling members and others depending on a practical application of the bearing, and slide member of a bearing for linear sliding motion may be utilized.

Although the load rolling surfaces of the divided blocks may be formed by individually applying grinding or the like to the respective blocks, it is preferable to simultaneously form the load rolling surfaces on the divided blocks, which are fixed to a jig for handling it as one component, in order to improve continuity of the load rolling surfaces of the slide member i.e., an assembly of the blocks.

Various variations such as use of ball tubes may be applied to a specific construction of the rolling member circulating means, which serves to scoop and return balls from one end of the continuously connected load rolling surfaces to the other end and cooperates with the load region to form an endless circulation path for the rolling members.

Further, the rolling members may be appropriately selected from cylindrical rollers, barrel rollers, balls and others.

Generally, so-called crowning may be applied to the load rolling surfaces of the slide member in order to achieve smooth circulation of the rolling members, and specifically, opposite side regions of the load rolling surfaces may be ground to a relatively large extent as compared with a middle region to form sections of the load rolling surfaces of the side regions into substantially convexly curved shapes. However, in the present invention, the construction requires to apply the crowning only to the load rolling surfaces of the divided blocks (hereinafter referred to "end blocks") located at opposite ends of the slide member. Therefore, a pair of end blocks to which the crowning is applied may be assembled together with an intended number of divided blocks (hereinafter referred to as "middle blocks") to which the crowning is not applied. This facilitates manufacturing of the slide member having a length corresponding to the number of the middle blocks.

According to the subject of the invention described above, by appropriately selecting the number of the divided blocks, the slide member can be facilely manufactured to have a long length corresponding to a movable member such as a table to be linearly guided, and the number of the load rolling members which rolls through the load region can be increased in accordance with the increase of the length of the slide member.

BRIEF DESCRIPTION OF THE DRAWINGS

DESCRIPTION OF THE REFERENCE NUMERAL

1: track bed, **2**: slide bed, **2***a*: end block (divided block), **2***b*: middle block (divided block), **3**: cover (rolling member circulating means), **4**: ball (rolling member), **11**: rolling surface, **24**: load rolling surface

DETAILED DESCRIPTION OF THE INVENTION

A bearing and a table for linear sliding motion of the invention will be described with reference to the accompanying drawings.

FIGS. **1** and **2** illustrate a first embodiment of the bearing for the linear sliding motion of the invention. The bearing is formed of a track member **1** mounted on a stationary or fixing portion, a slide bed **2** disposed over the track member **1**, a pair of covers **3***a* and **3***b* (rolling member circulating means) attached to opposite ends of the slide member **2**, and a large number of balls (rolling members) which bear a load between the track member **1** and the slide member **2**.

As shown in FIG. **1**, the slide member is formed of end blocks **2***a* located at opposite ends thereof and two middle blocks **2***b* disposed therebetween. These blocks are connected by connecting bolts **51** through connecting plates **5**. As shown in FIGS. **3** and **4**, each of the blocks **2***a* and **2***b* has a base **21***a* (**21***b*) and a pair of wings **22***a* (**22***b*) extending downward therefrom to form an inverted C-shaped section, and is provided at an inner surface of each wing **22***a* (**22***b*) with vertically spaced two grooves **23***a* (**23***b*) extending in an axial direction. In each groove, there is formed a load rolling surface **24***a* (**24***b*) having a curved section of a radius of curvature larger than a radius of a ball **4** which rolls thereon. Both the sleeves **22** are provided with no-load rolling apertures **25***a* (**25***b*) which form parts of rolling member circulating means and respectively correspond to the load rolling surfaces **24***a* (**24***b*). Upper surfaces of the base **21***a* (**21***b*) form mounting surfaces **26***a* (**26***b*) on which a movable member such as a table is mounted, and are provided with tapped bolt holes **27***a* (**27***b*) engaging mounting bolts (not shown). In FIG. **3**, numerals **28** and **29** indicate ball retainers, which are fixed to the bases **21***a* (**21***b*) and the wings **22***a* (**22***b*) by screws (not shown), respectively, and serve to prevent the balls **4** from dropping from the grooves **23***a* (**23***b*) on the blocks **2** when the slide bed **2** is removed from the track member **1**. Numerals **30***a* (**30***b*) indicate bolt holes engaging the coupling bolts **51**.

In this embodiment, continuity of the load rolling surfaces **24***a* and **24***b* of the blocks **2***a* and **2***b* coupled together is improved by simultaneously grinding the four blocks **2***a* and **2***b* to form the load rolling surface **24**. That is; the four blocks **2***a* and **2***b* are coupled together when fixed to a machine tool, and are handled as one integral slide bed when the grinding is applied thereto.

Crowning is applied to the load rolling surfaces **24***a* of the end blocks **2***a* after the grinding so that the balls **4** may be smoothly forced into the load region and released therefrom. On the other hand, the covers **3** are made from synthetic resin and are provided, as shown in FIGS. **5**–**7**, at their inner sides with ball return paths **31** which connect the load rolling surfaces **24***a* formed on the end blocks **2***a* and the corresponding no-load rolling apertures **25***a*. These ball return paths **31** are formed by semicircular guide pieces **33** which have guide surfaces **32** continuing to the load rolling surfaces **24***a* and are fitted over ball guide grooves **34** formed in the covers **33**. Numerals **35** indicate through holes through which fixing bolts (not shown) screwed into the end blocks **2** are inserted.

The track member **1** has a rectangular cross-sectional shape as shown in FIGS. **9** and **10** which has opposite sides recessed into trapezoids and also has recessed right and left shoulders. On inclined surfaces which are faced obliquely downward and formed by the above trapezoidal as well as inclined surfaces which are faced obliquely upward and formed by the recessed shoulders, there are provided rolling surfaces **11** which correspond to the load rolling surfaces **24***a* and **24***b* of the end blocks **2***a* and the middle blocks **2***b*, respectively. Numerals **12** indicate attaching holes through which fixing bolts (not shown) are inserted for engaging the fixing portion.

According to the bearing for the linear sliding motion of the invention thus constructed, as shown in FIG. **11**, a pair of end blocks **2***a* and the two middle blocks **2***b* are coupled together to form the long load rolling surface **24** by the continuous load rolling surfaces **24***a* and **24***b* of the blocks **2***a* and **2***b*, and also the slide member **2** provided with the no-load rolling apertures **25** corresponding to the load rolling surfaces **24** are obtained therefrom. Further, by attaching the covers **3** to the end blocks **2***a*, the endless ball circulation paths which connect the load rolling surfaces **24** and the no-load rolling apertures **25** of the slide member **2** are formed, whereby the slide bed **2** shown in FIG. **1** is completed.

FIG. **12** shows a first embodiment of a table for the linear sliding motion including two sets of the bearing for the linear sliding motion of the embodiment described above. The track member **1** are disposed on the fixing portion with a predetermined space between one another, and a table **7** is fixed to the slide members **2**.

With respect to the manufacturing of the table for the linear sliding motion shown in FIG. **12**, since the number of the middle blocks **2***b* can be appropriately determined in the bearing for the linear sliding motion of the embodiment, the slide members **2** having lengths depending on the sizes of the area in which the slide members **2** are disposed can be facilely manufactured.

Accordingly, it is possible to increase the number of the load balls **4** rolling between the load rolling surfaces **24** of the slide members **2** and the rolling surfaces **11** of the track beds **1** in accordance with the sizes of the table **7**, so that waving in the vertical and/or lateral directions, which may be caused by circulation of the balls **4**, can be minimized, and the linearity of the movement can be increased.

Since the lengths of the slide members **2** are increased depending on the sizes of the table **7**, a contact area between the slide members **2** and the table **7** can be increased, so that the rigidity of the table can be increased, as compared with the conventional bearing for the linear sliding motion shown in FIG. **20**.

In order to confirm the effectiveness of the invention, the inventors of the application and others have actually determined waving values of the table for the linear sliding motion shown in FIG. **12**. The measured results are as follows. For comparison, similar measurement has been made with respect to the table for the linear sliding motion employing the conventional bearing for the linear sliding motion shown in FIGS. **18** and **19** (this table will be called as a "comparison example"), and the result of this measurement also will be described below.

The slide bed **2** used in the experiment is slightly different from that of the first embodiment in that the slide member **2** is formed of four conventional bearing blocks **2***c* coupled together. Therefore, as shown in FIG. **15**, the crowning has been applied to the load rolling surface **24***c* of each block **2**. However, other structures such as the load rolling apertures **25***c* are similar to those of the bearing of the first embodiment.

With respect to the table for the linear sliding motion of the invention, variation of the waving values which may be caused by the various coupling states between the blocks **2***a* and **2***b* and the table **7** were determined by measuring the waving values in a case (experiment (1)) in which only the attaching bolts for the bolt holes **27***a* in the end blocks **2***a* were fastened and in a case (experiment (2)) in which all the attaching bolts for the bolt holes **27***a* and **27***b* in the end blocks **2***a* and the middle blocks **2***b* were fastened (see FIG. **13**).

The waving values were determined at points of distances and heights of A=97 mm, B=107 mm in FIGS. **13**, **14**, **18** and **19**, and C=360 mm. Spaces between the track beds in the embodiment and the comparison example are equal to each other, i.e., D=315 mm. The slide bed of the embodiment has a length of

E=341 mm, and the space between the slide members in the comparison example is 341 mm (F=341 mm).

The waving values obtained from the experiments are as follows.

Experiment (1)
vertical direction: 0.11 μm
lateral direction: 0.09 μm

Experiment (2)
vertical direction: 0.095 μm
lateral direction: 0.073 μm

Comparison Example
vertical direction: 0.2∼0.25 μm
lateral direction: 0.2∼0.25 μm

As can be seen from the results described above, in the table for the linear sliding motion using the bearing for the linear sliding motion according to the invention has the waving values which are substantially half or less than those of the comparison example, and thus the effectiveness of the invention can be confirmed. Further, it has been found that the waving values are improved in the bearing for the linear sliding motion according to the invention, if all the blocks c are fixed to the table.

The bearing for the linear sliding motion of the invention is not restricted to the first embodiment described-above, and, for example, it may have a sectional configuration as shown in FIG. **16**. Structures in FIG. **16** are similar to those described above, except for the sectional configuration of the block *2a* (*2b*), and thus the same reference numerals are allotted thereto without detailed description thereof.

INDUSTRIAL APPLICABILITY

According to the bearing for the linear sliding motion of the invention, as described hereinabove, the slide member can be constructed by coupling the divided blocks and thus the number of the load rolling members can be facilely increased in accordance with the sizes of the table to be linearly guided, so that the waving of the slide member can be minimized and the linearity of the movement can be increased.

According to the table for the linear sliding motion of the invention which employs these bearings, the movable member such as a machine tool mounted thereon can be smoothly and linearly guided with a high linearity, and thus works can be machined with a high accuracy.

Further, since the table can be supported by the slide members having the lengths corresponding to the sizes of the table, the table for the linear sliding motion can have a high rigidity, whereby the thickness can be reduced for achieving low cost.

What is claimed is:

1. A bearing for linear sliding motion, comprising:

a track member provided with rolling surfaces for rolling members such as balls or rollers extending in a lengthwise direction;

a slide member formed of a plurality of divided blocks which are provided with load rolling surfaces which in cooperation with said rolling surfaces and said rolling members supported therebetween, serve to transfer a load between said slide member and said track member, said divided blocks being jointed together to continuously connect said load rolling surfaces; and

rolling member circulating means for connecting opposing ends of said continuously connected load rolling surfaces to form an endless circulation path for said rolling members.

2. A bearing as claimed in claim **1** wherein said slide member is formed of a pair of end blocks having load rolling surfaces to which crowning is applied, and at least one middle block disposed between said end blocks.

3. A table for linear sliding motion, comprising: a track member provided with rolling surfaces for rolling members such as balls or rollers extending in a lengthwise direction;

a slide member formed of a plurality of divided blocks which are provided with load rolling surfaces which, in cooperation with said rolling surfaces and said rolling members supported therebetween, serve to transfer a load between said slide member and said track member, said divided blocks being jointed together to continuously connect said load rolling surfaces;

rolling member circulating means for connecting opposing ends of said continuously connected load rolling surfaces to form an endless circulation path for said rolling members; and

a table for supporting a movable member to be guided linearly, said table being fixed to said slide member for movement in a lengthwise direction of said track member.

[57] **ABSTRACT**

A reciprocating device has a construction, in which a slider is formed by fixing a table member to a bearing casing which is movable inside a track bed having a C-shaped section in a longitudinal direction thereof, and a continuous drive is disposed along the track bed for reciprocating the slider. A weight and sizes of the device can be reduced, and reciprocating motion without a pitching motion can be achieved. Accordingly, the invention can prevent generation of uncomfortable noises during a movement of the slider, and also can prevent reduction of durability of the device which may be caused by irregular wear of a bearing for guiding the slider.

RECIPROCATING DEVICE

FIELD OF THE INVENTION AND RELATED ART STATEMENT

The present invention relates to a reciprocating device particularly for smoothly and linearly reciprocating a predetermined member or object to which a load is applied.

Such reciprocating devices are well known that a large number of balls are rotatably disposed in endless paths and these balls rotate and circulate through the endless paths. An example of such reciprocating devices is disclosed in the Japanese Laid-Open Patent publication No. 1-320317 (320317/1989).

The reciprocating device disclosed in this publication is basically formed of, as shown in FIGS. 7–10, an elongated guide casing **60**, a guide rail **62** disposed in the guide casing **60** and extending along a longitudinal axis thereof, a traveler **64** which is slidable along the guide rail **62**, linear bearing mechanisms each having a large number of balls **66a** which individually rotate in a pair of vertically spaced endless paths, the linear bearing mechanisms being disposed between the guide rail **62** and the traveler **64**, and a linear drive device **68** for moving the traveler **64** with respect to the guide rail **62**.

This linear drive device **68** is formed of, as best shown in FIG. **10**, a flexible tension member, i.e., a toothed belt **74** which extends from the traveler **64**, is deflected at opposite end areas of the guide casing **60** toward the traveler **64** by deflection guide rolls **70** and **72** and is fixed thereto. This toothed belt **74** runs in a plane perpendicular to the endless paths of the linear bearings **66**, and has a middle region **74a** which runs along a bottom surface of the guide casing **60** in order to achieve a compact construction of the whole device. Therefore, the connecting points of the traveler **64** and the toothed belt **74** are spaced by a relatively long distance from a position at which the balls **66a** of the linear bearing mechanisms **66** are supported by the ball supporting paths of the guide rail **62**, because the deflection guide rolls **70** and **72** have large diameters.

This distance is also increased by a fact that the employed linear bearing mechanisms **66** have pairs of vertically spaced endless paths.

As described above, in the prior art reciprocating device, a point of application of the force for driving the device is spaced by a considerably long distance from a position at which the balls are supported by the ball supporting path grooves of the guide rail **62**, so that a large angular moment is applied to a driven member. Therefore, a wavy motion or pitching motion is caused in the driven member during reciprocating, which prevents smooth transportation. This also causes noise and an irregular wear of bearing surfaces, resulting in reduction of durability.

OBJECT AND SUMMARY OF THE INVENTION

It is an object of the invention to overcome the problems of the prior art described above, to prevent a wavy motion which may be caused when a reciprocating device is driven and to reduce noise generated when the device is driven.

A reciprocating device according to the invention comprises: a track bed having a base and a pair of flanges, which are perpendicularly projected from the base with a predetermined space between each other and each are provided at the inner surface with one ball rolling groove extending in a reciprocating direction; a bearing casing formed of a pair of upper and lower plates provided with annular grooves and coupled together, said coupled plates forming a pair of endless ball tracks each of which is formed of a linear load ball region, a no-load ball region and turning regions connecting them; a large number of balls which circulate along the endless ball tracks in the bearing casing, said load ball regions being provided with recesses through which the balls partially project and are rotatably fitted in the ball rolling grooves in the track bed for slidably supporting the bearing casing with respect to the track bed; a table member fixed to an upper portion of the bearing casing for cooperating with the bearing casing to form a slider; and drive means which runs in a plane parallel to the endless ball tracks and having a portion fixed to the slider for reciprocatively driving the slider with respect to the track bed.

According to the features of the invention described above, the drive means such as a chain, wire or belt which runs in the plane parallel to the endless tracks is reciprocated by an appropriate drive source, e.g., a motor. Thereby, the bearing casing and the table member are smoothly reciprocated with respect to the track bed by means of the balls which partially project through the recesses provided in the no-load ball regions in the endless ball tracks and are fitted in the ball rolling grooves. Since the belt or the like runs in the plane parallel to the endless ball tracks, a distance from a point of application of a driving force by the motor to the belt or the like to supporting points in which the balls are supported by the rolling grooves is reduced. Further, the bearing casing is formed of the paired upper and lower plates provided with the concave grooves and these plates are coupled to form a pair of the endless ball tracks including the linear load ball regions, no-load ball regions and turning regions connecting them. Therefore, the bearing casing has a reduced vertical thickness, and thus the whole device has a small height. Thereby, the table member with an object mounted thereon has a small inertia force when it starts or stops.

According to the reciprocating device of the invention, since there is a short distance between the point at which the driving force is applied by the drive means such as a motor to the driven means and the supporting points at which the balls are supported by the ball rolling grooves, a moment applied to the slider formed of the bearing casing and the table member is reduced, and thus wavy motion of an assembly which may be caused by the moment is suppressed.

Therefore, the reciprocating device of the invention enables remarkably smooth reciprocating motion, as compared with the prior art, and also can reduce noises during operations.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. **1** is a plan view illustrating an embodiment of the reciprocating device according to the invention, in which an upper half of the Figure shows a portion lower than a belt and a lower half shows a top view;

FIG. **2** is a side view of a reciprocating device shown in FIG. **1**;

FIG. **3** is a cross section taken along line III—III in FIG. **2**;

FIG. **4** is a schematic view for illustrating a relationship between a ball and a ball rolling groove;

FIG. 5 is a schematic view showing one of tongues provided at opposite ends of recesses;

FIG. 6 is a cross section corresponding to FIG. 3 and illustrating an embodiment different from the reciprocating device shown in FIGS. 1-3;

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Specific embodiments of a reciprocating device of the invention will be described below with reference to the accompanying drawings.

A reciprocating device 2 according to the invention is formed, as shown in FIGS. 1-3, a track bed 30, a slider 10 having a bearing casing 6 which is reciprocatively slidable along the track bed 30 and a table member 8 fixed to an upper portion of the bearing casing 6, pulleys mounted at longitudinally opposite ends of the track bed 30 and a belt 24 retained around these pulleys 12 and 14 for driving the slider 10.

The track bed 30 has a C-shaped section and is formed of a base 30*b* and a pair of flanges 30*a* perpendicularly projected from opposite sides of the base 30*b*. At an inner side of each flange 30*a*, one ball rolling groove 34 linearly extends parallel to a running direction of the belt 24 for supporting balls 32 in the bearing casing 6, as will be described later. As shown in FIG. 4, the ball rolling groove 34 is formed of two ball rolling surfaces 34*a* and 34*b* which intersects each other and has a cross section of a Gothic arch shape. In FIG. 3, the base 30*b* and the paired flanges 30*a* of the track bed 30 are formed by an integral member. However, members which have L-shaped cross sections and are provided with the ball rolling grooves 34 may be disposed on the upper surface of the base with the ball rolling grooves 34 faced inwardly.

Brackets 4*a* and 4*b* are fixed at the opposite ends of the track bed 30 for supporting the pulleys 12 and 14, respectively. In the Figure, the pulley 12 is an idle pulley and is rotatably supported by a shaft 16 mounted in the bracket 4*a*. The pulley 14 is a drive pulley, above which an electrical motor 20, i.e., a step motor is disposed and is fastened to the bracket 4*b* by bolts 18. The pulley 14 is fixed to a rotary shaft 22 of the electric motor 20. The belt 24 is retained around the pulleys 12 and 14. The pulleys 12 and 14 are provided at their inner surfaces with a plurality of teeth 26, which engage teeth 26 provided at engagement grooves 28 of the pulleys 12 and 14 for enabling accurate motion control without slip. If the accurate motion control is not required, the teeth 26 of the belt 24 and the engagement grooves 28 of the pulleys 12 and 14 may be eliminated.

The pulley 12 and the belt 24 are covered from the upper side with a cover 36 having a C-shaped section, so that the pulley 12 and the belt 24 may not be exposed to the exterior and an article or member (not shown) on the table member 8 may not fall into the track bed. The cover 36 is fixed at its opposite ends to the brackets 4*a* and 4*b*.

Then, description will be made with respect to a slider which is reciprocated inside the track bed 30 by the belt 24. As shown in FIGS. 2 and 3, this slider is formed of the bearing casing 6 and the table member 8.

The table member 8 is located above the track bed 30 and the bearing casing 6. The table member 8 has a substantially rectangular shape in a top view, and has a hollow rectangular cross section recessed at an upper portion as shown in FIG. 3. The table member 8 may be manufactured from a sheet by a press working. A hollow portion in the table member 8 forms a space through which the belt 24 retained around the pulleys 12 and 14 and the cover 36 pass. The table member 8 reciprocates, surrounding the belt 24 and the cover 36. An elongated fixing block member 38 is fixed onto the bottom portion of the table member 8 by bolts 40. An attaching block 42 is engaged to the fixing block member 38 by bolts 44. The belt 24 has a portion pinched between the fixing block member 38 and the attaching block 42, and thus is fixed to the table member 8.

In FIG. 3, although the cover 36 is located at the hollow portion in the table member 8, it may be located outside the table member 8 covering an opening of the table member 8.

The table member 8 is fixed at a position above the bearing casing 6 by appropriate means such as welding.

The bearing casing 6 is formed of a pair of upper and lower plates 6*a*, each of which is provided with a pair of annularly extending grooves forming upper and lower halves of a pair of endless ball tracks 46. Each track 46 is formed of a linear load ball region 6*b*, a no-load ball region 6*c* and return regions (not shown) connecting them.

Each plate 6*a* is manufactured by a press working of, e.g., a thin steel plate. The bearing casing 6 is an assembly of the paired plates 6*a* which are opposed to each other and are jointed by appropriate means such as spot welding or riveting in the illustrated embodiment. The bearing casing 6 has a wear resistance increased by surface hardening such as nitriding.

The bearing casing 6 is provided at its opposite side walls defining the linear load ball regions 6*b* with windows or recesses 48. The balls 32 located at the linear load ball regions 6*b* partially project outwardly through the recesses 48. The balls 32 projected from the endless ball tracks to the outside of the bearing casing 6 are rotatably fitted with the ball rolling grooves 34 in the track bed 30 described above. Since the ball rolling grooves 34 have the cross sections of the Gothic arch shapes defined by the ball rolling surfaces 34*a* and 34*b*, as described before, each ball 32 projected through the recess 48 contacts the surface of the ball rolling groove 34 through two points, as shown in FIG. 4. Therefore, as compared with the prior art device in which each ball contacts the surface of the ball rolling groove through one point, the illustrated embodiment can increase the stability of movement with respect to-a moment load.

According to the construction described above, since the bearing casing 6 can freely reciprocate in the track bed owing to rolling of the balls 32, the belt 24 fixed to the table member 8 may be rotated through a predetermined extent by the electric motor 20 for applying a reciprocating motion of a stroke corresponding to the rotated extent of the belt 24 to the slider 10.

Further, as shown in FIGS. 2 and 5, at opposite ends of each recess 48 provided at the load ball region in the bearing casing 6, there are provided tongues 50 extending into spaces between the balls 32 located at the endmost positions of the recess 48 and a central portion of the ball rolling groove **34** of the Gothic arch shape. The tongues **50** serves to enable smooth entry of the loaded balls **32**, which are rotated by the movement of the bearing casing **6**, into the no-load region in the endless track **46**. Since the balls are smoothly scooped from the load regions to the no-load regions by the tongues **50** provided at the opposite ends of the recesses, noises which may be caused by collision of the balls can be reduced.

In the above embodiment, the belt **24** is disposed at the hollow portion of the table member **8**. However, as shown in FIG. **6**, the belt **24** may be disposed below the slider **10** formed of the bearing casing **6** and the table member **8** and may be accommodated in the track bed **30**.

What is claimed is:

1. A reciprocating device comprising:

a track bed having a base and a pair of flanges perpendicularly projected from said base with a predetermined space between each flange and each flange is provided at an inner surface with one ball rolling groove extending in a reciprocating direction;

a bearing casing formed of a pair of upper and lower plates provided with annular grooves and coupled together, said coupled plates forming a pair of endless ball tracks each of which is formed of a linear load ball region, a no-load ball region and turning regions connecting them;

a large number of balls which circulate along said endless ball tracks in said bearing casing, said load ball regions being provided with recesses through which said balls partially project and are rotatably fitted in said ball rolling grooves in said track bed for slidably supporting said bearing casing with respect to said track bed;

a plate-like table member fixed to an upper portion of said bearing casing and cooperating with said bearing casing to form a slider; and

drive means including a motor, a continuous drive member driven by said motor, and a pair of pullies with each pulley rotatably mounted at one end of said track with said driven member rounded about each of said pullies and running in a plane parallel to said endless ball tracks; and

means fixing said continuous drive member to said slider, whereby said motor reciprocatively drives said continuous drive member and said slider with respect to said track bed.

2. A reciprocating device as claimed in claim **1** wherein said continuous drive member is a belt.

3. A reciprocating device as claimed in claim **1** wherein each of said ball rolling grooves in the track bed is defined by two ball rolling surfaces intersecting each other, and has a cross section of a Gothic arch shape.

4. A reciprocating device as claimed in claim **1** wherein said bearing casing is provided at opposite ends of said recesses formed in the load ball regions with tongues extending into spaces between said balls and central portions of said ball rolling grooves, respectively.

5. A reciprocating device as claimed in claim **1** wherein said continuous drive member is a chain.

6. A reciprocating device as claimed in claim **1** wherein said continuous drive member is a wire.

7. A reciprocating device as claimed in claim **1** wherein said means fixing said drive member to said slider is fixed to an upper portion of said table member.

8. A reciprocating device as claimed in claim **1** wherein said means fixing said drive member to said slider is fixed to a lower portion of said bearing casing and said drive member rounds said pullies internally of a channel formed by said track bed.

9. A reciprocating device as claimed in claim **1** wherein said pullies are mounted for rotation on vertical spindles.

RECTILINEAR SLIDING BEARING AND ASSEMBLING METHOD THEREOF

TECHNICAL FIELD

This invention relates to a rectilinear sliding bearing for rectilinearly guiding a moving body such as a table in a slide section of NC machines, machine tools, industrial robots, etc., and to a method of assembling the rectilinear sliding bearing to the moving body.

BACKGROUND ART

A conventional rectilinear sliding bearing comprises a rail to be fixed to a fixing section of a machine or the like which has axially-extending rolling surfaces on which rolling elements roll, a slider movable along the rail which has a load zone including load rolling surfaces provided in confronting relation to the rolling surfaces of the rail and a no-load zone for connecting both ends of the load zone, the two zones defining endless tracks, and a number of rolling elements for bearing loads between the load rolling surfaces of the slider and the rolling surfaces of the rail while circulating through the endless tracks. In practice, for example, a plurality of such rails are laid in parallel on the fixing section, and a moving body such as a table is connected to the slider.

This type of rectilinear sliding bearing can possess the so-called automatic adjusting function (of reducing a moment load acting on the bearing) by making the angle of contact of the load rolling surface with the rolling element close to the angle of contact of an outer ring with a ball in front combination form of an angular contact ball bearing (which is one type of rotary bearing) to short the distance between two working points appearing when loads act on the bearing. On the other hand, the bearing can also possess the so-called automatic aligning function (of causing a moment load acting on the slider to be effectively absorbed between a bearing race and a block) by dividing the slider having the automatic adjusting function into a substantially cylindrical bearing race having endless tracks and a block having a table attaching surface which is fitted on the bearing race.

In these rectilinear sliding bearings, even when there is the attaching error of the rail relative to the fixing section (such as the error in parallelism or, level of two or more rails), the slider can be smoothly moved and the moving body can be rectilinearly guided with accuracy.

However, where the rail has some vertical waving resulting from the disorder of the surface of the fixing section on which the rail is laid, improper tightening of rail fixing bolts, etc., the slider moving along such a rail undergoes pitching in the moving direction, so that the machining accuracy of a machine tool, for example, mounted on the moving body is degraded.

To overcome such a defect, Japanese Patent Laid-Open No. 62-188636 has proposed a rectilinear guide device. This, as shown in FIGS. 21 and 22, is characterized in that a gap retaining washer (c) is interposed between a slider (a) and a moving body (b) to retain a gap between them, and an attaching bolt (d) is passed through the gap retaining washer (c) and screwed into the slider (a) to connect the slider (a) and the moving body (b) together, whereby the structural error of rail (e) can be absorbed or moderated by means of the relative displacement between the slider (a) and the moving body (d) that results from the elastic deformation of the attaching bolt (d) (specifically, by a sliding contact action between an arcuate convex surface (f) of the gap retaining washer (c) and an arcuate concave surface (g) of the slider (a) or moving body (b)). In this rectilinear guide device, the pitching of the slider (a) is absorbed between the slider (a) and the moving body (b); therefore, the positional accuracy in movement of the moving body (b) is enhanced to overcome the foregoing defect.

However, the proposed rectilinear guide device has other defects. First, since the sliding contact action between the gap retaining washer (c) and the slider (a) or moving body (b) is utilized, when the amount of tightening of the attaching bolt (d) is large or the moving body (b) suffers a large load/weight, the coupling force between the slider (a) and the moving body (b) becomes strong, and a large frictional force acts between the arcuate convex surface (f) and the arcuate concave surface (g), whereby the function of relative displacement owing to sliding contact cannot be exerted sufficiently.

Second, if the area of sliding contact is decreased for the purpose of sufficiently exerting the function of relative displacement owing to sliding contact, a concentrated load acts on the slider (a) and the moving body (b), whereby the individual components (a), (b) tend to be deformed or damaged.

In view of the foregoing defects, it is an object of the present invention to provide a rectilinear sliding bearing of high reliability which can effectively absorb or moderate the attaching error of a rail.

It is another object of the present invention to provide a method of assembling a rectilinear sliding bearing which makes it possible to accomplish the first object.

DISCLOSURE OF THE INVENTION

According to a first feature of the present invention, a rectilinear sliding bearing comprises a slider of substantially C-shape in cross section having a horizontal portion, a pair of wing portions extending downward from both ends of the horizontal portion, a concave portion opened on the lower side which is defined by the horizontal portion and the two wing portions, an attaching surface to which a moving body such as a table is fixed by means of coupling bolts, a downward-facing upper load rolling surface and an upward-facing lower load rolling surface axially formed in the inner surface of each of the wing portions, and no-load rolling paths for defining endless tracks in conjunction with the upper and lower load rolling surfaces; a rail having rolling surfaces formed in confronting relation to the upper and lower load rolling surfaces along which the slider moves; and a number of rolling elements, such as balls or rollers, for bearing loads between the upper and lower load rolling surfaces of the slider and the rolling surfaces of the rail while circulating through the endless tracks; and is characterized in that the attaching surface of the slider is made in the form of a curved surface having a small radius of curvature in the moving direction so that when the moving body is fixed by tightening the coupling bolts, the attaching surface is brought into pressure contact with the moving body to undergo elastic deformation, and the elastic deformation of the attaching surface causes relative displacement between the slider and the moving body, thereby absorbing or moderating the structural error of the rail.

According to a second feature of the present invention, the foregoing first rectilinear sliding bearing is modified so that the slider is composed of a bearing race formed by cutting off an axially-extending portion of a cylindrical body to define the concave portion opened on the lower side, the inner surface of the concave portion having the upper and lower load rolling surfaces; and a block fitted on the bearing race and having the attaching surface to which the moving body such as a table is fixed by means of the coupling bolts.

According to a third feature of the present invention, the foregoing first rectilinear sliding bearing is modified so that the slider has a horizontal portion, tow wing portions extending downward from both ends of the horizontal portion, a concave portion opened in an obliquely downward direction which is defined by the horizontal portion and the two wing portions, an attaching surface to which a moving body such as a table is fixed by means of coupling bolts, a downwardly-inclined load rolling surface axially formed in the inner surface of one wing portion, an upwardly-inclined load rolling surface axially formed in the inner surface of the other wing portion, and no-load rolling paths for defining endless tracks in conjunction with the load rolling surfaces.

According to the present invention, a method of assembling a rectilinear sliding bearing in which a slider moves rectilinearly along a rail with interposition of a number of endlessly-circulatable rolling elements, such as balls or rollers, by fixing a moving body such as a table to the slider, comprises the steps of making the moving-body attaching surface of the slider into the form of a curved surface having a small radius of curvature in the moving direction, and bringing the moving body into pressure contact with the attaching surface by tightening coupling bolts to cause the attaching surface to undergo elastic deformation, whereby the elastic deformation of the attaching surface causes relative displacement between the slider and the moving body to absorb or moderate the structural error of the rail.

The workings of the foregoing technical matter will be described with reference to FIG. 20.

Since either an attaching surface (j) of a slider (h) or a surface (k) to be attached of a moving body (i) is curved (the surface of the slider (h) is curved in the drawing), before tightening coupling bolts (l), only the top of the curved surface (j) is in contact with the flat surface (k) (see FIG. 20(*a*)).

When the coupling bolts (l) are tightened, the slider (h) with the curved surface (j) undergoes elastic deformation if the rigidity of the moving body (i) with the flat surface (k) is sufficiently high, and the area of contact between the slider (h) and the moving body (i) increases with the amount of tightening of the coupling bolts (l) (see FIG. 20(*b*)).

The pressure of surface contact in a contacting zone is the highest at the center X of the curved surface, decreases gradually as departing from the center X, and becomes substantially zero at each Y of the contacting zone. Therefore, when the slider (h) itself causes pitching in the moving direction, the coupling bolts undergo elastic deformation, such as elongation or nontraction, the slider (h) rolls in relation to the moving body (i) to shift the contacting zone between them as shown in FIG. 20(*c*), and thus, pitching is prevented from transferring to the moving body (i).

In FIG. 20, to facilitate understanding of the foregoing fundamental action, the radius of curvature of the attaching surface is shown in exaggerated form.

In the present invention, a small radius of curvature being given to the moving-body attaching surface of the slider is determined on the basis of an estimated magnitude of the attaching error of the rail. When the rail itself causes large vertical waving after being attached to a fixing section, the radius of curvature of the attaching surface is made somewhat larger to make difficult the transfer of the pitching of the slider to the moving body. For example, where the axial or longitudinal length of the slider is 100 mm, the difference between the sectional height at the center of the attaching surface of the slider and the sectional height at either axial end of the slider is set to about 0.01 mm to 0.05 mm.

The assembling method of the present invention is applicable to any slider of the foregoing three kinds of rectilinear sliding bearings, provided that the slider freely slidable on the rail has the endless tracks through which the rolling elements circulate and the curved moving-body attaching surface has a small radius of curvature. To enhance the moving accuracy of the moving body being attached to the slider, it is preferable that each of the two wing portions of the slider should have the downward-facing upper load rolling surface and the upward-facing lower load rolling surface to give the automatic adjusting function to the slider as is the case of the first kind of rectilinear sliding bearing. Further, it is preferable that the slider should be divided into the bearing race and the block to give the automatic aligning function to the slider as is the case of the second kind of rectilinear sliding bearing. Further, the moving-body attaching surface may be formed integrally on the slider, or a separate member having such an attaching surface may be mounted on the slider.

The number of endless tracks, the angle of inclination of the load rolling surface, and the like may be changed or modified depending on the field of applications of the bearing, the structure of the slider, and the like. Further, the no-load rolling path may be provided by boring a no-load rolling hole in the slider or attaching a rolling-element retainer to the slider.

The rolling element which circulates through the endless track may be in the form of a cylindrical roller, barrel-shaped roller, ball, etc.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a plan view showing a first embodiment of a rectilinear sliding bearing according to the present invention;

FIG. 2 is a side view corresponding to FIG. 1;

FIG. 3 is a sectional front view showing the rectilinear sliding bearing in assembled form according to the first embodiment;

FIGS. 4 and 5 are a front view and a side view, respectively, showing a slide body of the rectilinear sliding bearing according to the first embodiment;

FIGS. 6 and 7 are a perspective view and a sectional view, respectively, showing a rail according to the first embodiment;

FIG. 8 is a front view showing a cover according to the first embodiment;

FIG. 9 is a sectional view taken along line I—I in FIG. 8;

FIG. 10 is a sectional view taken along line II—II in FIG. 9;

FIG. 11 is a perspective view showing a guide piece according to the first embodiment;

FIG. 12 is a sectional front view showing the rectilinear sliding bearing according to the first embodiment in which a conical spring washer is attached to a coupling bolt;

FIG. 13 is a sectional view showing a load working point in the slide body according to the first embodiment;

FIG. 14 is a schematic perspective view showing a spacer;

FIGS. 15 and 16 are a side view and a sectional front view, respectively, showing a second embodiment of the rectilinear sliding bearing according to the present invention;

FIGS. 17, 18 and 19 are a plan view, a side view and a sectional front view, respectively, showing a third embodiment of the rectilinear sliding bearing according to the present invention;

FIG. 20 is an explanatory view showing a fundamental method of assembling the rectilinear sliding bearing according to the present invention; and

FIGS. 21 and 22 are a side view and da sectional front view, respectively, showing a conventional bearing.

BEST MODE FOR CARRYING OUT THE INVENTION

A rectilinear sliding bearing and an assembling method thereof of the present invention will now be described in greater detail with reference to the accompanying drawings.

FIRST EMBODIMENT

FIGS. 1 through 11 show a first embodiment of the rectilinear sliding bearing according to the present invention.

The rectilinear sliding bearing comprises a slide body 1 of substantially C-shape in cross section which has a horizontal portion 1*a*, left and right wing portions 1*b* extending downward from both ends of the horizontal portion, and a concave portion opened on the lower side; a pair of covers 3 attached to the front and rear ends of the slide body 1; a pair of ball retainers 6 provided inside the left and right wing portions 1*b* of the slide body 1; a rail 2 fixed to a machine or the like by means of fixing bolts acting as fixing means; and a number of balls 4 for bearing loads between the slide body 1 and the rail 2 while circulating through endless ball tracks defined by the slide body 1 and the covers 3.

As shown in FIGS. 4 and 5, the slide body 1 is substantially C-shaped in cross section, and the inner surface of each of the left and right wing portions 1*b* has upper and lower load rolling surfaces 11 and 12 extending in the axial direction whose radius of curvature is larger than the radius of the balls. The normal line of the upper load rolling surface 11 is inclined downward at 45 degrees to the horizontal and the normal line of the lower load rolling surface 12 is inclined upward at the same angle. Each of the left and right wing portions 1*b* has no-load rolling holes 13 formed therein correspondingly to the upper and lower load rolling surfaces 11 and 12. The slide body 1 has on its upper side an attaching surface 14 which is curved in the moving or axial direction with a small radius of curvature, and attaching holes 15 formed therein in which coupling bolts 51 passing through a moving body 5 from top to bottom are fitted. Reference symbol 16 designates screw holes in which fixing or attaching bolts 31 for the covers 3 are fitted.

Each of the covers 3 made of synthetic resin is fixed to either axial end of the slide body 1 by the fixing bolts 31. As shown in FIGS. 8 through 11, each cover 3 has ball turning paths 32 formed therein for connecting the load rolling surfaces 11 and 12 and the corresponding no-load rolling holes 13 of the slide body 1. Each ball turning path 32 is completed by fitting a semi-circular guide piece 33 (having a guide surface 34 made compatible with the load rolling surface 11, 12) in each ball guide groove 35 formed in each cover 3. Reference symbol 36 designates an attaching hole through which the fixing bolt 31 is passed.

Each of the ball retainers 6 is fabricated by stamping a metal plate as to have a substantially L-shape in cross section and two elongate holes whose width is smaller than the diameter of the balls 4. Each ball retainer 6 acts to eject the balls 4 rolling on the load rolling surfaces 11 and 12 from the elongate holes and bring them into contact with the rolling surfaces of the rail 2, and also to prevent the balls 4 from coming off the load rolling surfaces 11 and 12 of the slide body 1 when a slider B is detached from the rail 2.

The slider B having the endless tracks through which the balls 4 circulate is completed by attaching the covers 3 and the ball retainers 6 to the slide body 1.

The rail 2 is fabricated by cutting off a part of trapezoidal shape in cross section from either lateral side of a raw body of rectangular shape in cross section and cutting off left and right shoulder portions. Each downward-facing oblique surface formed by cutting off the trapezoidal part defines a lower rolling surface 22 corresponding to the lower load rolling surface 12 formed in the inner surface of the wing portion 1*b* of the slide body, and each upward-facing oblique surface formed by cutting off the shoulder portion defines an upper rolling surface 21 corresponding to the upper load rolling surface 11 formed also in the inner surface of the wing portion 1*b* of the slide body. The rail 2 has fixing-bold insertion holes 23 formed in a central portion orthogonally to the upper surface at adequate intervals in the longitudinal direction thereof, through which fixing bolts 24 to be screwed to a fixing section 7 are passed.

To assemble the rectilinear sliding bearing of the foregoing structure to a rectilinear sliding table for guiding a machine in rectilinear reciprocative motion, as shown in FIG. 3, the rail 2 is fixed to the fixing section 7 such as a bed by means of the fixing bolts 24, and the moving body 5 is fixed by means of the coupling bolts 51 to the attaching surface 14 of the slider B capable of moving along the rail 2.

In this assembling process, the attaching surface or curved surface 14 of the slide body 1 is compressed by tightening the coupling bolts 51, whereby the slider B and the moving body 5 are fixed together. At this time, the coupling bolts 51 undergo elastic deformation, such as elongation or contraction, and the slider B and the moving body 5 are brought into rolling contact with each other, thereby causing relative displacement.

Therefore, when the slider B receives external vertical loads because of the presence of the attaching error and the like of the rail 2, relative displacement occurs between the slider B and the moving body 5, whereby fluctuations in posture of the slider B owing to external loads are absorbed or moderated, so that the accuracy in rectilinear motion of the moving body 5 is kept high.

In this embodiment, the angle of contact of the balls 4 with the load rolling surfaces 11 and 12 and with the rolling surfaces 21 and 22 in relation to the horizontal is

45 degrees over the whole length of the endless track; thus, the rectilinear sliding bearing is similar in ball contact angle to a so-called angular contact bearing (which is one type of rotary bearing). Therefore, a load working point when a load acts on the slider B is located at P_1 and P_2 as shown in FIG. **13**, so that the distance L between these working points becomes short. Consequently, even when loads acting at P_1 and P_2 are not in balance, a moment load acting on the slider B can be reduced, that is, the rectilinear sliding bearing has the so-called automatic adjusting function. Accordingly, with the advantage that the moving body **5** and the slider B can undergo relative displacement, the present invention can absorb the attaching error of the rail **2** to smoothly guide the moving body **5** in rectilinear motion with accuracy.

SECOND EMBODIMENT

Although the first embodiment includes the curved attaching surface **14** provided on the slider B of the rectilinear sliding bearing having the automatic adjusting function, this second embodiment is implemented by applying the present invention to a rectilinear sliding bearing having the so-called automatic aligning function.

FIGS. **15** and **16** show a second embodiment of the rectilinear sliding bearing. That is, the slider B comprises a bearing race **9** made of a cylindrical body those axially-extending portion is cut off to define a concave portion opened on the lower side (an upper half portion of the rail **2** is passed through this concave portion with a certain gap left between them), and a block **1** which has an attaching surface **14** for fixing the moving body **4** by means of the coupling bolts **51** and surrounds the bearing race **9** tightly. The angle of contact of the balls **4** with the load rolling surfaces **11** and **12** differs from that of the first embodiment. Other structural points of the second embodiment are substantially identical with those of the first embodiment.

In the bearing race **9**, the inner surface of the concave portion has two upper load rolling surfaces **11** and two lower load rolling surfaces **12** extending in the axial direction, the upper load rolling surface **11** faces downward orthogonally to the horizontal plane, the lower load rolling surface **12** faces upward at 30 degrees to the horizontal plane, and upon contact of the balls **4**, the automatic adjusting function as in the first embodiment acts on the bearing race **9**. A ball retainer **6** is provided inside the concave portion of the bearing race **9** as to cover the load rolling surfaces **11** and **12**, and in conjunction with the inner surface of the bearing race **9**, defines endless ball tracks.

The block **1** has a curved surface on the upper side which defines an attaching surface **14** for the moving body **5** as in the first embodiment, and a concave portion on the lower side which receives the bearing race **9**.

In this second embodiment, when a moment load acts on the slider B, relative displacement occurs between the bearing race **9** and the block **1**, whereby no excessice load is imposed on the balls **4**, so that the balls **4** can slide on the rail **2**.

Therefore, because of the presence of the curved attaching surface **14** of the slider B, the accuracy in rectilinear motion of the moving body **5** is never influenced by the pitching of the slider B resulting from the waving of the rail **2**, and the moving body **5** can be smoothly guided even where the attaching error of the rail **2** is comparatively large.

THIRD EMBODIMENT

This embodiment is substantially identical with the first embodiment, except that the shape of the slider B, the angle of contact of the balls **4**, and the number of endless tracks differ from those of the first embodiment.

As shown in FIGS. **17** through **19**, the slider B comprises a slide body **1** of substantially L-shape in cross section which has a horizontal portion **1***a*, two wing portions **1***b* extending downward from both ends of the horizontal portion, and a concave portion opened in an obliquely downward direction; a pair of covers **3** attached to the front and rear end face of the slide body **1**; and ball retainers **6** attached to the lower ends of the wing portions **1***b*.

The inner surface of each of the wing portions **1***b* of the slide body has a load rolling surface **11, 12**; a no-load rolling hole **13** is formed in each wing portion correspondingly to the load rolling surface **11, 12**; and these load rolling surfaces and no-load rolling holes in conjunction with the ball retainers **6** and ball turning paths formed in the covers **3** define endless ball tracks. A moving-body attaching surface **14** of the slide body **1** is curved as in the first embodiment. Reference symbol **10** designates a sidewise pressure bolt for pressing one side face of the slide body **1** to apply pre-load to the balls **4**.

Therefore, in this third embodiment also, the coupling bolts **51** underto elastic deformation, such as elongation or contraction, and the slider B and the moving body **5** are brought into rolling contact with each other to cause relative displacement, so that because of the presence of the curved attaching surface **14**, the accuracy in rectilinear motion of the moving body **5** is never influenced by the pitching of the slider B resulting from the waving of the rail **2**.

Each of the foregoing embodiments uses the coupling bolts **51** which completely connect the slider B and the moving body **5** together while allowing them to undergo relative displacement. However, where a conical spring washer **53** is interposed between the moving body **5** and the coupling bolt **51** as shown in FIG. **12** and the coupling bolt **51** is fastened to such an extent as not to completely compress the conical spring washer **53**, relative displacement occurs easily between the slider B and the moving body **5**; in this case, even small fluctuations in posture of the slider B can be absorbed or moderated, thereby improving the accuracy in rectilinear motion of the moving body **5**.

As will be appreciated, several components of the second and third embodiments which are identical with or correspond to those of the first embodiment are designated by the same reference symbol, with their description not duplicated.

Each of the foregoing embodiments shows the attaching surface directly provided on the upper side of the slide body. However, the present invention may be implemented by the use of a spacer **8** as shown in FIG. **14**.

This spacer **8** is in the form of a substantially flat plate with through holes **82** for the coupling bolts **51**, whose one face is curved to define a curved surface **81**. To assemble the rectilinear sliding bearing of the present invention, the spacer **8** is interposed between the slide body **1** and the moving body **5** where the respective attaching surfaces of the slide body **1** and the moving body **5** are flat.

Therefore, by the use of the spacer **8**, the assembling method of the present invention can be readily practiced in or applied to the conventional rectilinear sliding bearing whose attaching surface **14** for the moving body **5** is flat, this resulting in the same effect as is the case of the rectilinear sliding bearing according to the present invention.

Here, it is no matter whether the curved surface **81** faces the slider B or the moving body **5**.

In the drawings showing the embodiments, to facilitate understanding of the present invention, the radius of curvature of the attaching surface is shown in exaggerated form to such an extent that anyone can visually perceive it.

INDUSTRIAL APPLICABILITY

As described above, according to the rectilinear sliding bearing and the assembling method thereof of the present invention, the pitching of the slider resulting from the attaching error of the rail can be absorbed or moderated, the positional accuracy of the moving body can be enhanced, and the machining accuracy of a machine tool or the like mounted on the moving body can be improved.

Further, the slider and the moving body are brought into tolling contact with each other to undergo relative displacement, and such relative displacement is not impeded by the frictional force between them; therefore, the foregoing effect can always be exerted.

Further, the curved surface is compressed in proportion to the amount of tightening of the coupling bolt and the amount of load/weight of the moving body to result in a corresponding area of surface contact between the slider and the moving body; therefore, loads never act on one point of the slider concentratedly, and the durability of the slider can be enhanced.

What is claimed is:

1. A rectilinear sliding bearing comprising

a slider of subtantially C-shape in cross section having a horizontal portion, a pair of wing portions extending downward from both ends of the horizontal portion, a concave portion opened on the lower side which is defined by the horizontal portion and the two wing portions, an attaching surface to which a moving body such as a table is fixed by means of coupling bolts, a downward-facing upper load rolling surface and an upward-facing lower load rolling surface axially formed in the inner surface of each of the wing portions, and no-load rolling paths for defining endless tracks in conjunction with the upper and lower load rolling surfaces.

a rail having rolling surfaces formed in confronting relation to the upper and lower load rolling surfaces along which the slider moves, and

a number of rolling elements, such as balls or rollers, for bearing loads between the upper and lower load rolling surfaces of the slider and the rolling surfaces of the rail while circulating through the endless tracks,

chracterized in that the attaching surface of the slider is made in the form of a curved surface having a small radius of curvature in the moving direction so that when the moving body is fixed by tightening the coupling bolts, the attaching surface is brought into pressure contact with the moving body to undergo elastic deformation, and the elastic deformation of the attaching surface causes relative displacement between the slider and the moving body, thereby absorbing or moderating the structural error of the rail.

2. A rectilinear sliding bearing according to claim **1**, wherein the slider is composed of

a bearing race formed by cutting off an axially-extending portion of a cylindrical body to define the concave portion opened on the lower side, the inner surface of the concave portion having the upper and lower load rolling surfaces, and

a block fitted on the bearing race and having the attaching surface to which the moving body such as a table is fixed by means of the coupling bolts.

3. A rectilinear sliding bearing comprising

a slider having a horizontal portion, two wing portions extending downward from both ends of the horizontal portion, a concave portion opened in an obliquely downward direction which is defined by the horizontal portion and the two wing portions, an attaching surface to which a moving body such as a table is fixed by means of coupling bolts, a downwardly-inclined load rolling surface axially formed in the inner surface of one wing portion, an upwardly-inclined load rolling surface axially formed in the inner surface of the other wing portion, and no-load rolling paths for defining endless tracks in conjunction with the load rolling surfaces,

a rail having rolling surfaces formed in confronting relation to the load rolling surfaces along which the slider moves, and

a number of rolling elements, such as balls or rollers, for bearing loads between the load rolling surfaces of the slider and the rolling surfaces of the rail while circulating through the endless tracks,

characterized in that the attaching surface of the slider is made in the form of a curved surface having a small radius of curvature in the moving direction so that when the moving body is fixed by tightening the coupling bolts, the attaching surface is brought into pressure contact with the moving body to undergo elastic deformation, and the elastic deformation of the attaching surfaces causes relative displacement between the slider and the moving body, thereby absorbing or moderating the structural error of the rail.

4. A method of assembling a rectilinear sliding bearing in which a slider moves rectilinearly along a rail with interposition of a number of endlessly-circulatable rolling elements, such as balls or rollers, by fixing a moving body such as a table to the slider, comprising the steps of

making the moving-body attaching surface of the slider into the form of a curved surface having a small radius of curvature in the moving direction, and

bringing the moving body into pressure contact with the attaching surface by tightening coupling bolts to cause the attaching surface to undergo elastic deformation,

whereby the elastic deformation of the attaching surface causes relative displacement between the slider and the moving body to absorb or moderate the structural error of the rail.

[57] **ABSTRACT**

Herein disclosed are a linear sliding bearing and a linear sliding table, in which rollers have their sides pressed to suppress their rolling motions by the frictional force so that the sliding resistance of a sliding bed sliding on a track base may be increased. Since a predetermined rigidity can be attained even in the axial direction of the track base by increasing or decreasing the sliding resistance arbitrarily, a workpiece of high machining precision can be achieved when the bearing or table is used in a machine apparatus such as a machine tool.

LINEAR SLIDING BEARING AND LINEAR SLIDING TABLE

TECHNICAL FIELD

The present invention relates to a linear sliding bearing for linearly guiding a moving member to be slid in a machine tool such as a NC machine or a slide of an industrial robot.

BACKGROUND ART

In case a workpiece is to be machined by a machine tool, for example, loads accompanying the machining in various directions are generally exerted between the machine tool and the workpiece, although depending upon the kinds of machining such as cutting or polishing, the material of the workpiece or the machining conditions. The loads act as reaction forces upon the machine tool and the workpiece. If the machine tool and the workpiece are completely fixed at the instant of machining against the loads, the machining can be ideally accomplished in a drastically improved precision.

In the case of machining of the workpiece using such machine tool, one of the machine tool or the workpiece is fixed whereas the other is moved by means of a mechanism such as a linear sliding bearing.

The linear sliding bearing known to used for this purpose is constructed to include: a track base having axial races; a sliding bed having endless tracks which are formed of load regions having load races facing the races of the track base and no-load regions providing the communicating connections between the two ends of the load regions; and rollers circulating in the endless tracks for bearing the loads between the races of the track base and the load races of the sliding bed. Thus, the linear sliding bearing can bear the loads in the four directions, i.e., radial, inversely radial and rightward and leftward directions. In the linear sliding bearing of this kind, moreover, the rigidities in the four directions are enhanced by applying a prepressure to the rollers to bear the four-directional loads to be generated between the machine tool and the workpiece during the machining, so that the accompanying chatter marks and vibrations may be suppressed as much as possible to improve the machining precision. In connection with the axial direction of the track base, on the other hand, frictions in the movements are suppressed with a view to lightening the loads upon the feeding drive system such as a feeder of screw and nut type or a motor mechanism. The rigidity necessary for the machining in the axial direction of the track base relies exclusively upon that of the feeding drive system.

Incidentally, the rigidity of the feeding drive system is determined, if the system is the feeder of screw and nut type, by the rigidity of the feed screw or nut itself, the rigidity of the support of the feed screw or nut, and the rigidity of the motor for applying a rotating force to the feed screw. In order to increase the rigidity of the feeding drive system, it is necessary to enlarge the size of the feed screw or nut or to raise the output of the motor. Thus, the increase in the rigidity of the feeding drive system is intrinsically limited by the problems which are caused by increasing the size of the apparatus or by raising the cost for the feeding drive system.

As various products are required to be the more precise in the industry of recent years, a machine apparatus such as the machine tool for machining the products is required to have its machining precision improved the better. Thus, the linear sliding bearing taking a leading role for the machining precision of the various machine apparatus is requested to improve the machining precision.

It is, therefore, an object of the present invention to provide a linear sliding bearing which can have not only the rigidities of four directions, i.e., the radial, inversely radial, rightward and leftward directions but also a predetermined rigidity in the axial direction of the track base.

Another object of the present invention is to provide a linear sliding bearing which can apply the rigidity in the axial direction of the track base, if necessary, and adjust the level of the rigidity.

Still another object of the present invention is to provide a linear sliding table which can mount a machine apparatus such as a machine tool for machining of high precision.

DISCLOSURE OF THE INVENTION

According to the present invention, there is provided a linear sliding bearing comprising: a track base having axial roller races and fixed to a machine apparatus or the like; a sliding bed formed with endless tracks, which have load regions having load races facing said roller races and no-load regions for effecting the communicating connections between the two ends of said load regions, and made movable along said track base; and a multiplicity of rollers circulating in said endless tracks for bearing the load between the load races of said sliding bed and the races of said track base, wherein the improvement resides in that said sliding bed includes: side walls extending along one-end sides of said load races for regulating the axial movements of load rollers rolling on said load races; and pressure means for pressing the one-end sides of said load rollers in the axial direction and the other sides onto said side walls.

According to the present invention, there is provided a linear sliding table placed on the upper surface of a sliding bed of a bearing which comprises: a track base having axial roller races and fixed to a machine apparatus or the like; a sliding bed formed with endless tracks, which have load regions having load races facing said roller races and no-load regions for effecting the communicating connections between the two ends of said load regions, and made movable along said track base; and a multiplicity of rollers circulating in said endless tracks for bearing the load between the load races of said sliding bed and the races of said track base, said sliding bed including: side walls extending along one-end sides of said load races for regulating the axial movements of load rollers rolling on said load races; and pressure means for pressing the one-end sides of said load rollers in the axial direction and the other sides onto said side walls.

In these linear sliding bearing and table, moreover, the pressure means presses the one-end sides of the load rollers in the axial direction and the other sides to the side walls formed on the sliding bed or beds. As a result, the rollers have their two-end sides pressed onto the pressure means and the sliding bed or beds so that their rolling motions are suppressed by the frictional forces to increase the sliding resistances of the sliding bed or beds rolling on the track base or bases.

In this technical means, the sliding bed can be selected from a suitable structure if it has the endless tracks for circulating the rollers and can slide freely on the track base and if it has the side walls for regulating the axial movements of the load rollers. The structure conceivable can be exemplified in various manners: by one including a horizontal portion and a pair of skirts depending from the two sides of the horizontal portion to form a recess in its lower side and formed with a pair of righthand and lefthand upper load races and lower load races extending axially on their inner sides; by a generally inverted L-shape which has a horizontal portion and skirts depending from one end of the horizontal portion and which has load regions extending along the lower side of the horizontal portion and the inner sides of the skirts and depends from the tack base; or by a generally rectangle having load regions extending axially along its sides and arranged along the sides of the track base. Incidentally, the aforementioned side walls to be given to the sliding bed may be formed directly on the sliding bed or indirectly on another member to be attached to the sliding bed.

On the other hand, the aforementioned endless tracks may be suitably exemplified by changing the designs of their numbers or the angle of inclination of the load races in accordance with the usage of the bearings or the structure of the sliding bed. Moreover, the no-load regions may be suitably exemplified by forming the no-load rolling holes in the sliding bed or the no-load rolling tracks by roller retainers to be attached from the outside to the sliding bed.

On the other hand, the rollers to be circulated in the aforementioned endless tracks may be suitably selected from cylindrical rollers or barrel-shaped rollers. In the former case using the cylindrical rollers, the load races of the sliding bed and the races of the track base are planar along the circumferences of the rollers. In the latter case using the barrel-shaped rollers, the load races and the races are curved.

On the other hand, the pressure means may be suitably exemplified by changing the designs of the structure or shape if it can press the one-end sides of the load rollers in their axial direction and the other sides to the aforementioned side walls. In order to simplify the apparatus structure, it is preferable to form the retaining surfaces for preventing the load rollers from coming out under non-pressure conditions, at the leading ends of the pressure surfaces for pressing the sides of the load rollers. In order to make the linear sliding bearing compact, moreover, the pressure means may preferably be so attached to the sliding bed as is positioned in the gap between the track base and the sliding bed and as will press the load rollers of two rows simultaneously. In order to prevent the pressed load rollers from being abruptly locked, still moreover, the pressure means may preferably press the load rollers of that of several rows, which must bear the highest load. Incidentally, the method for the pressure means to apply the pressure may be exemplified by changing the designs, e.g., by actuating the pressure means continuously by means of the fastening forces of bolts or the elastic forces of springs, or by actuating the pressure means instantly in the required place of the track base by means of a fluid such as oil.

Furthermore, the bearings of the aforementioned linear sliding table may be suitably exemplified by deciding the number of bearings to be disposed below the table in dependence upon the width of the table or the load to be exerted upon the table.

BRIEF DESCRIPTION OF DRAWINGS

FIG. **1** is a front elevation showing a first embodiment of a linear sliding bearing according to the present invention; FIGS. **2** and **3** are a side elevation and a top plan view of the linear sliding bearing of the first embodiment; FIG. **4** is a cut-away perspective view showing the linear sliding bearing according to the first embodiment; FIG. **5** is a section taken along line I—I of FIG. **3**; FIG. **6** is a section taken along line II—II of FIG. **3**; FIG. **7** is a top plan view showing a braking plate exemplifying the pressure means of the linear sliding bearing according to the first embodiment; FIG. **8** is a section taken along line III—III of FIG. **7**; FIG. **9** is a section taken along line IV—IV of FIG. **7**; FIG. **10** is an exploded perspective view showing the assembly of the braking plate of the linear sliding bearing according to the first embodiment; FIG. **11** is a section showing an essential portion in the state, in which no oil pressure is applied to the braking plate while the linear sliding bearing according to the first embodiment is used; FIG. **12** is a section showing an essential portion in the state, in which an oil pressure is applied to the braking plate while the linear sliding bearing according to the first embodiment is used; FIG. **13** is a sectional front elevation showing a second embodiment of the linear sliding bearing of the present invention; FIG. **14** is a sectional front elevation showing a third embodiment of the linear sliding bearing of the present invention; FIG. **15** is a sectional front elevation showing a fourth embodiment of the linear sliding bearing of the present invention; and FIG. **16** is a sectional front elevation showing an embodiment of the linear sliding table according to the present invention.

BEST MODE FOR CARRYING OUT THE INVENTION

A linear sliding bearing and a linear sliding table will be described in detail in the following with reference to the accompanying drawings.

First Embodiment

The linear sliding bearing according to the present embodiment is constructed, as shown in FIGS. **4** and **5**, to include: a sliding bed **1** formed generally into a C-shaped section having a horizontal portion **1***a* and righthand and lefthand skirts **1***b* depending from the two ends of the horizontal portion **1***a* to leave a groove in its lower side; a pair of roller guides **6** mounted on the lower ends of the righthand and lefthand skirts **1***b* of the sliding bed **1**; a track base **2** fixed to a machine apparatus by fixing means such as fixing bolts; a number of rollers **4** circulating in an endless roller race formed in the sliding bed **1** for bearing a load between the sliding bed **1** and the track base **2**; and a braking plate **5** positioned between the lower side of the horizontal portion **1***a* and the upper surface of the track base **2** and made suitably movable up and down in accordance with the pressure of a fluid introduced from the sliding bed **1** for pushing the sides of load rollers **4***a* rolling on a load race formed on the sliding bed **1**.

The sliding bed **1** constitutes load regions of an upper endless roller track and a lower endless roller track in the axial direction, respectively, on the two ends of the lower side of the horizontal portion **1***a* and the lower ends of the inner surfaces of the righthand and lefthand skirts **1***b*. The load regions are formed with load races on which the rollers **4** are caused to roll. Above the righthand and lefthand skirts **1***b*, moreover, there are formed relief roller tracks **11** which correspond to the load regions of the upper endless roller tracks. On the other hand, the righthand and lefthand skirts **1***b* are formed at their lower ends with no-load regions which correspond to the load regions of the lower endless roller tracks. At the lower ends of the load races of the righthand and lefthand upper endless roller tracks, moreover, there are formed side walls **12** for regulating the axial movements of the load rollers **4***a* which are caused to roll on those load races. Incidentally, the aforementioned load regions are inclined at such predetermined angles that their four races are parallel with the upper races and the lower races of the track base **2** when the bearing of the present invention is assembled. The sliding bed **1** is formed at its two widthwise end portions with mounting holes **13** into which mounting bolts are inserted from the lower to upper surfaces. On the other hand, the lower side of the horizontal portion **1***a* of the sliding bed **1** provides a portion for mounting the braking plate **5** acting as pressure means for pushing the sides of the load rollers **4***a* and is formed at its center with an oil hole **14** which extends vertically therethrough to admit the oil for applying the pressure to the braking plate **5**. The lower side of the horizontal portion **1***a* is further formed with mounting holes **15** which are to be engaged with screws extending through the braking plate **5**.

To each of the longitudinal end portions of the sliding bed **1** described above, there is fixed by fixing bolts **31** a cover **3** which is made of a synthetic resin. These covers **3** are formed with grooves for establishing the communicating connections between the load regions formed in the sliding bed **1** and the corresponding relief roller tracks **11** or the no-load regions.

On the other hands, the aforementioned roller guides **6** are formed to have a generally L-shaped section by pressing a metallic plate or injection-molding a hard synthetic resin, as shown in FIG. **5**, and are secured to the lower ends of the righthand and lefthand skirts 1b of the sliding bed **1** by means of screws. Thus, the load and no-load regions formed at the lower ends of the righthand and lefthand skirts **1***b* form the endless roller tracks to guide the individual rollers, together with the roller turning portions which are formed in the covers **3**.

On the other hand, the aforementioned track base **2** is formed into such a section that a rectangle has its two sides notched to form a trapezoid whose two side shoulders further notched to form downward slopes and upward slopes. Of these slopes, the lower ones provide lower races **21** which correspond to the lower endless roller tracks formed a the lower ends of the skirts **1***b* of the sliding bed **1**, whereas the upper ones provide upper races **22** which correspond to the upper endless roller tracks formed at the two ends of the lower side of the horizontal portion **1***a* of the sliding bed **1**. Moreover, the track base **2** is formed at its central portion with fixing bolt mounting holes **23** for receiving fixing bolts which are fastened to a stationary portion. The bolt mounting holes **23** are vertically extended in the upper surface of the track base **2** and are bored at a suitable spacing in the longitudinal direction of the track base **2**.

As shown in FIG. **5** or **6**, the aforementioned braking plate **5** is a generally plane plate having a rectangular shape, which is positioned, when assembled, in the gap between the lower side of the horizontal portion **1***a* of the sliding bed **1** and the upper surface of the track base **2**. The braking plate **5** is made of a softer material such as brass than that of the rollers and is given functions to push, if necessary, the sides of the load rollers **4***a* rolling on the upper races of the track base **2** and to align and retain the load rollers **4***a*. As better seen from FIGS. **7**, **8** and **9**, the braking plate **5** its upper surface recessed to form an oil pocket **51** which is to be filled up with the oil flowing into and out of the oil hole **14** formed in the center of the horizontal portion **1***a* of the sliding bed **1**. The braking plate **5** is formed on its two widthwise end portions with pressure surfaces **52** which are sloped to face downward the sides of the load rollers **4***a*, when the bearing is assembled, thereby to suitably press the sides of the load rollers **4***a* rolling on the upper races of the track base **2**. Those pressure surfaces **52** are longitudinally formed at their lower ends with retaining surfaces **53** for preventing the load rollers **4***a* rolling on the upper roller tracks of the track base **2** from coming out so that they may be associated with the side walls **12** formed in the sliding bed **1**, to prevent the load rollers **4***a* from coming out. Moreover, the braking plate **5** is formed at its widthwise center with through holes **54** which are vertically extended from the bottom to the top for receiving screws to be fastened to the lower side of the horizontal portion **1***a* of the sliding bed **1**. Here, the lower side and pressure surfaces **52** of the braking plate **5** are so finished that the gap between the lower side of the braking plate **5** and the upper surface of the track base **2** may be larger, when the bearing is assembled, than that between the pressure surfaces **52** and the sides of the load rollers **4***a* belonging to the upper endless roller tracks.

The braking plate **5** thus constructed is mounted in the sliding bed **1**, as better seen from FIG. **10**, by fitting an 0-ring **7** in the inner periphery of the aforementioned oil pocket **51** for preventing the oil leakage, by inserting screws **9** together with dishspring washers **8** into the lower sides of the aforementioned through holes **54** and by fastening the screws **9** in the mounting holes formed in the lower side of the horizontal portion **1***a* of the sliding bed **1**. At this time, the fastening forces of the screws **9** are decided: such that the dish-spring washers **8** sandwiched between the heads of the screws **9** and the lower side of the braking plate **5** are freely subjected to elastic deformations by the pressures exerted upon the braking plate **5** whereas the aforementioned 0-ring **7** is always retained in close contact with the lower side of the horizontal portion **1***a;* and such that the braking plate **5** is pushed up to the lower side of the horizontal portion **1***a* of the sliding bed **1** by the elastic forces of the dish-spring washers **8** when no pressure is applied to the braking plate **5**.

The linear sliding bearing thus constructed according to the present embodiment is used by fixing the track base **2** to the machine apparatus by means of the fixing bolts, by mounting a table carrying a variety of machine tools on the sliding bed **1** sliding along the track base **2** by means of the mounting bolts, by connecting a hydraulic apparatus (although not shown) to be driven in response to an instruction signal outputted from a control unit (although not shown) to the oil hole **14** of the sliding bed **1**, and by applying an arbitrary pressure to the oil which fills up the oil pocket **51** of the braking plate **5** in a necessary place over the track base **2**.

In case, at this time, no oil pressure is applied to the oil pocket **51**, the braking plate **5** is raised to the lower side of the horizontal portion **1***a* of the sliding bed **1** by the elastic forces of the dish-spring washers **8** to keep its pressure surfaces **52** away from contact with the sides of the load rollers **4***a* rolling on the upper races of the track base **2**, so that the load rollers **4***a* can freely roll on the races of the track base **2** to slide the sliding bed **1** on the track base **2** with a slight sliding resistance (as seen from FIG. **11**). In case, on the contrary, the oil pressure P is applied to the oil pocket **51**, it pushes the braking plate **5** downward so that the pressure surfaces **52** of the braking plate **5** push the one-end sides of the load rollers **4***a* in the axial direction to bring the other sides of the load rollers **4***a* into contact with the side walls **12** formed on the sliding bed **1**. As a result, fricitonal forces are established between the sides of the load rollers **4***a* and the pressure surfaces **52** and the side walls **12** to increase the rolling resistances of the load rollers **4***a* so that high sliding resistances are exerted upon the sliding bed **1** sliding on the tack base **2** (as seen from FIG. **12**).

Thus, in the linear sliding bearing of the present embodiment, the sliding resistance of the sliding bed **1** can be increased by applying the pressure to the oil pocket **51** of the braking plate **5**, thereby to strengthen the axial rigidity of the track base **2** of the linear sliding bearing.

In the linear sliding bearing of the present embodiment, moreover, the oil pressure to be applied to the oil pocket **51** can be suitably adjusted to establish the axial rigidity of the track base **2**, if necessary, and to adjust it to an arbitrary level.

Second Embodiment

A linear sliding bearing according to the present embodiment is substantially identical to that of the first embodiment except in that two braking plate **5** are disposed at the inner sides of the righthand and lefthand skirts **1***b* of the sliding bed **1** to push the sides of two rows of load rollers **4***a* rolling on the upper and lower races of the track base **2**, as shown in FIG. **13**.

The sliding bed **1** is formed between the load regions of the upper endless roller track and the lower endless roller track with grooves for housing the braking plates **5** and at its righthand and lefthand skirts **1***b* with bolt mounting through holes in which are fastened pressure bolts **10** for pressing the braking plates **5**.

Thus, the braking plates are housed in the grooves, and the pressure bolts **10** fitted in their mounting holes are driven forward internally of the skirts. Then, the fastening forces of the pressure bolts **10** are exerted as the pressures upon the braking plates **5** so that the braking plates **5** push the sides of the load rollers **4***a* rolling in the load regions. As a result, the sliding resistance of the sliding bed **1** is increased as in the first embodiment.

Thus, in the linear sliding bearing of the present embodiment, the axial rigidity of the track base **2** can be strengthened by adjusting the turns of the pressure bolts **10**.

Third Embodiment

A linear sliding bearing according to the present embodiment is substantially identical to that of the first embodiment except in that adjust bolts **10** are extended through the sliding base **1** from the to horizontal surface to engage with the braking plates **5** positioned at the inner sides of the righthand and lefthand skirts of the sliding bed **1** so that they may be fastened to raise the braking plates **5** to push the sides of the load rollers **4***a* rolling on the upper races of the track base **2**, as shown in FIG. **14**. The axial rigidity of the track base **2** can also be strengthened according to the present embodiment.

Fourth Embodiment

A linear sliding bearing according to the present embodiment is a modification of the third embodiment and is substantially identical to that of the third embodiment except in that the angle of inclination of the load races of the upper endless roller tracks whereas the braking plate **5** is arranged at the lower side of the horizontal portion **1***a* of the sliding bed **1**, as shown in FIG. **15**, so that the sides of the righthand and lefthand upper load rollers **4***a* may be pushed by the single adjust bolt **10**.

Fifth Embodiment

FIG. **16** shows an embodiment of the linear sliding table according to the present invention. A pair of righthand and lefthand track bases **2** are arranged in parallel at a suitable spacing, and a pair of righthand and lefthand sliding beds **1** having braking plates **5** are slid along the external sides of the track bases **2**. A table T is mounted to ride over the paired sliding beds **1** so that it may linearly guide a machine apparatus carried thereon.

According to the linear sliding table of the present embodiment, like the linear sliding bearings of the foregoing embodiments, the sliding resistance can be increased, while the sliding beds **1** are sliding on the track bases **2**, to strengthen the rigidity of the linear sliding table in the axial direction of the track bases.

Industrial Applicability

As has been described hereinbefore, according to the linear sliding bearing of the present invention, the sliding resistance of the sliding bed siding on the track base can be adjusted to apply or adjust the rigidity in the axial direction of the track base, if necessary.

By applying a strong pressure to the load rollers by the pressure means to prevent the load rollers from rolling, moreover, the sliding bed can be continuously fixed in one portion on the tack base so that the pressure means can function as the locking mechanism of the linear sliding bearing.

According to the linear sliding table of the present invention, still moreover, like the aforementioned linear sliding bearing, the rigidity in the axial direction of the track bases can be applied to the table or adjusted so that a workpiece can be machined highly precisely in case the machine apparatus such as a machine tool is placed on the table.

I claim:

1. A linear sliding bearing comprising: a track base having axial roller races and fixed to a machine apparatus; a sliding bed formed with endless tracks, which have load regions having load races facing said roller races and no-load regions for effecting the communicating connections between the two ends of said load regions, and made movable along said track base; and a multiplicity of rollers circulating in said endless tracks for bearing the load between the load races of said sliding bed and the races of said track base, wherein the improvement resides in that said sliding bed includes: side walls extending along one-end sides of said load races for regulating the axial movements of load rollers rolling on said load races; and pressure means for pressing the one-end sides of said load rollers in the axial direction and the other sides onto said side walls.

2. A linear sliding bearing as set forth in claim **1**, wherein said sliding bed includes a horizontal portion and a pair of skirts depending from the two dies of said horizontal portion to form a recess in its lower side, said skirts being formed with a pair of righthand and lefthand upper load races and lower load races extending axially on their inner sides, and wherein said pressure means arranged at the lower side of said horizontal portion for pressing the load rollers rolling on said righthand and lefthand load races.

3. A linear sliding bearing as set forth in claim **1**, wherein said sliding bed includes a horizontal portion and a pair of skirts depending from the two dies of said horizontal portion to form a recess in its lower side, said skirts being formed with a pair of righthand and lefthand upper load races and lower load races extending axially on their inner sides, and wherein said pressure means arranged at the inner side of said skirt portion for pressing at least either those of the load rollers, which roll on said upper load races and said lower load races.

4. A linear sliding bearing as set forth in claim **1**, wherein said sliding bed is formed into a generally rectangular shape and longitudinally along its one side with a pair of upper and lower load races, and wherein said pressure means arranged between said upper load races and said lower load races for pressing at least either those of the load rollers, which roll on said upper load races and said lower load races.

5. A linear sliding bearing as set forth in any one of claims **1** to **4**, wherein said pressure means is formed, at the leading end of a pressure surface for pressing the sides of said load rollers, with a retaining surface for preventing said load rollers under a non-pressure condition from coming out.

6. A linear sliding table placed on the upper surface of a sliding bed of a bearing which comprises: a track base having axial roller races and fixed to a machine apparatus or the like; a sliding bed formed with endless tracks, which have load regions having load races facing said roller races and no-load regions for effecting the communicating connections between the two ends of said load regions, and made movable along said track base; and a multiplicity of rollers circulating in said endless tracks for bearing the load between the load races of said sliding bed and the races of said track base, said sliding bed including: side walls extending along one-end sides of said load races for regulating the axial movements of load rollers rolling on said load races; and pressure means for pressing the one-end sides of said load rollers in the axial direction and the other sides onto said side walls.

[57] **ABSTRACT**

A linear sliding bearing which is composed of a ball-and-roller bearing mechanism and a sliding bearing mechanism. The gap between a track base and a sliding bed is adjusted by gap adjusting bolt, to adjust the pressure of contact between the two faces constituting the sliding bearing mechanism thereby to adjust the sliding resistance of the sliding bed to the track base at will. As a result, a rigidity can be given even in the axial direction of the track base so that the machining precision of a workpiece can be improved when a machine apparatus such as a machine tool is to be used.

LINEAR SLIDING BEARING

TECHNICAL FIELD

The present invention relates to a linear sliding bearing for linearly guiding a moving member to be slid in a machine tool such as a NC machine or a slide of an industrial robot.

BACKGROUND ART

In case a workpiece is to be machined by a machine tool, for example, loads accompanying the machining in various directions are generally exerted between the machine tool and the workpiece, although depending upon the kinds of machining such as cutting or polishing, the material of the workpiece o the machining conditions. The loads act as reaction forces upon the machine tool and the workpiece. If the machine tool and the workpiece are completely fixed at the instant of machining, the machining can be ideally accomplished in a drastically improved precision.

In the case of machining of the workpiece using such machine tool, one of the machine tool or the workpiece is fixed whereas the other is moved by means of a mechanism such as a linear sliding bearing.

The linear sliding bearing to be used for this purpose is exemplified by one which comprises: a sliding bed having a section of generally inverted C-shape and including a horizontal portion and a pair of skirts depending downward from the two ends of the horizontal portion to form a recess at its lower side and formed in its inner sides with a pair of upper and lower load races extending longitudinally thereof and with relief ball tracks corresponding to the load races; a track base having its upper portion fitted in the recess of said sliding bed, while maintaining a predetermined spacing inbetween, and formed with rolling races corresponding to said load races; a pair of covers attached to the front and rear end faces of said sliding bed and formed in their inner sides with guide grooves for providing the communicating connections between the end portions of the load races and the relief ball tracks of said sliding bed to form endless ball tracks; a multiplicity of balls circulating in said endless ball tracks to bear the loads between the load races of said sliding bed and the rolling grooves of said track base; and gap adjusting means for adjusting the gap between said sliding bed and said track base to apply and adjust a pilot pressure (as disclosed in Japanese Patent Publications Nos. 61-34,934 and 61-48,009). Thus, the linear sliding bearing can bear the loads in the four directions, i.e., radial, inversely radial and rightward and leftward directions. In the linear sliding bearing of this kind, moreover, the rigidities in the four directions are enhanced by applying or adjusting the pilot pressure to the rollers to bear the four-directional loads to be generated between the machine tool and the workpiece during the machining, so that the accompanying chatter marks and vibrations may be suppressed as much as possible to improve the machining precision. In connection with the axial direction of the track base, on the other hand, what is principally aimed at is to lighten the loads upon the feeding drive system such as a feeder of screw and nut type or a linear motor mechanism. The rigidity necessary for the machining in the axial direction of the track base relies exclusively upon that of the feeding drive system.

Incidentally, the rigidity of the feeding drive system is determined, if the system is the feeder of screw and nut type, by the rigidity of the feed screw or nut itself, the rigidity of the support of the feed screw or nut, and the rigidity of the servo-motor for applying a rotating force to the feed screw. In order to increase the rigidity of the feeding drive system, it is necessary to enlarge the size of the feed screw or nut or to raise the driving force of the servo-motor. Thus, the increase in the rigidity of the feeding drive system is intrinsically limited by the problems which are caused by increasing the size of the apparatus or by raising the cost for the feeding drive system.

As various products are required to be the more precise accurate in the industry of recent years, a machine apparatus such as the machine tool for machining the products is required to have its machining precision improved the better. Thus, the linear sliding bearing taking a leading role for the machining precision of the various machine apparatus is requested to improve the machining precision.

It is, therefore, an object of the present invention to provide a linear sliding bearing which can have not only the rigidities of four directions, i.e., the radial, inversely radial, rightward and leftward directions but also a predetermined rigidity in the axial direction of the track base.

Another object of the present invention is to provide a linear sliding bearing which can apply the rigidity in the axial direction of the track base, if necessary, and adjust the level of the rigidity.

Still another object of the present invention is to provide a linear sliding bearing which is equipped with a lock mechanism capable of fixing the sliding bed in a target position when the sliding bed is moved along the track base to that position.

A further object of the present invention is to provide a linear sliding bearing which is enabled to accomplish the machining of high precision by adopting a machine apparatus such as a machine tool.

DISCLOSURE OF THE INVENTION

According to the present invention, there is provided a linear sliding bearing comprising: a sliding bed having a section of generally inverted C-shape and including a horizontal portion and a pair of skirts depending downward from the two ends of the horizontal portion to form a recess at its lower side and formed in its inner sides with a pair of load races extending longitudinally thereof and with relief ball tracks corresponding to the load races; a track base having its upper portion fitted in the recess of said sliding bed, while maintaining a predetermined spacing inbetween, and formed with rolling races corresponding to said load races; a pair of covers attached to the front and rear end faces of said sliding bed and formed in their inner sides with guide grooves for providing the communicating connections between the end portions of the load races and the relief ball tracks of said sliding bed to form endless ball tracks; and a multiplicity of rolling members circulating in said endless ball tracks to bear the loads between the load races of said sliding bed and the rolling grooves of said track base, wherein the improvement resides: in that the load races of said sliding bed are formed in the inner sides and at the roots of said skirts; in that the races of said track base corresponding to the load races of said sliding bed are formed at the shoulders of said track base; in that there is formed, between each of the leading ends of the inner sides of the skirts of said sliding bed and each of the two sides of the track base facing the former, a sliding bearing mechanism which include convex and concave portions having upward taper surfaces and downward taper surfaces shaped to be fitted in a wedged manner; and in that there is interposed, between said sliding bed and a table to be mounted on the upper surface of said sliding bed, gap adjusting means which includes a suspension or pressure mechanism for elastically deforming the horizontal portion of said sliding bed, whereby the pressure of contact between the upward and downward taper surfaces of said sliding bed and the downward and upward taper surfaces of said track base is adjusted by adjusting the gap between said sliding bed and said track base by said gap adjusting means.

Thus, in the linear sliding bearing according to the present invention, a ball-and-roller bearing mechanism having a low sliding resistance is constituted by the load races of the sliding bed, the races of the track base, and the rolling members rolling between these races, and a sliding bearing mechanism is constituted by the convex and concave portions having upward and downward taper surfaces positioned in the lower portions of the sliding bed and the track base and facing each other. By adjusting the gap between the sliding bed and the track base by the gap adjusting means, the pressure of contact between the upward and downward taper surfaces of the sliding bed and the downward and upward taper surfaces of the track base can be adjusted to give and adjust a rigidity to the ball-and-roller bearing mechanism and to adjust the sliding resistance of the sliding bearing mechanism thereby to give and adjust the rigidity in the axial direction of the track base. In necessary, moreover, the sliding bearing mechanism can be acted as a lock mechanism.

In the present invention, the rolling members for rolling between the sliding bed and the track base while bearing the loads may be exemplified by balls or rollers, but the former balls are preferable from the standpoint of smoothening the gap adjustment.

In the sliding bearing mechanism to be formed between the leading ends of the inner sides of the skirts of the sliding bed and the two sides of the track base, moreover, the convex portions or the concave portions may be formed in either of the sliding bed and the track base. From the standpoint of better smoothening the gap adjustment, it is preferable that the leading ends of the inner sides of the skirts of the sliding bed are formed with the convex portions of a generally trapezoidal section having the upward and downward taper surfaces whereas the two sides of the track base are formed with the convex portions of the shape having the downward and upward taper surfaces and corresponding to the convex portions.

Still moreover, the gap adjusting means for adjusting the gap between the sliding bed and the track base may be the suspension or pressure mechanism which can apply a suspension or pressure and accordingly an elastic deformation to the central portion of the sliding bed to adjust the gap between the sliding bed and the track base. The suspension or pressure mechanism may be specifically exemplified by forming a pair of mounting faces on the upper surface of the horizontal portion of the sliding bed over and longitudinally of the two skirts of the sliding bed, by mounting a table on the paired mounting faces by a plurality of fastening bolts to leave a predetermined gap between the upper surface of the horizontal portion and the lower side of the table and between the mounting faces, by equipping the table with gap adjusting bolts for applying suspending or pressing forces to the horizontal portion through the table at an intermediate position of the paired mounting faces, and by turning the gap adjusting bolts to elastically deform the horizontal portion of the sliding bed thereby to adjust the gap between the sliding bed and the track base according to the elastic deformation. The gap adjusting bolts may be a suspending bolt to be fastened in a gap adjusting screw hole formed in an intermediate position of the horizontal portion of the sliding bed, pressing bolts extending downward to abut against the intermediate position of the horizontal portion of the sliding bed, or a combination of plural suspending and pressing bolts of which the suspending bolt is arranged between a pair of the pressing bolts along the intermediate position of the horizontal portion of the sliding bed.

BRIEF DESCRIPTION OF DRAWINGS

FIG. **1** is a front elevation showing a first embodiment of a linear sliding bearing according to the present invention;

FIGS. **2** and **3** are a side elevation and a top plan view of the linear sliding bearing of the first embodiment;

FIG. **4** is a cut-away perspective view showing the linear sliding bearing according to the first embodiment;

FIG. **5** is a section showing the state in which the linear sliding bearing according to the first embodiment is used;

FIG. **6** is a section showing the sliding bed of the linear sliding bearing according to the first embodiment;

FIG. **7** is a perspective view showing the track base of the linear sliding bearing according to the first embodiment;

FIG. **8** is a section showing an essential portion in the state in which the concave portion at the sliding bed of the sliding bearing mechanism of the linear sliding bearing according to the first embodiment has no pressure of contact with the concave portion of the track base;

and FIG. **9** is a section showing an essential portion in the state in which the concave portion at the sliding bed of the sliding bearing mechanism of the linear sliding bearing according to the first embodiment has pressure of contact with the concave portion of the track base.

BEST MODE FOR CARRYING OUT THE INVENTION

The linear sliding bearing according to the present invention will be specifically described in the following in connection with th embodiment thereof with reference to the accompanying drawings.

A linear sliding bearing B according to the present invention is shown in FIGS. 1 to 4. This bearing B is constructed to comprise: a sliding bed 1 of a generally inverted C-shaped section including a horizontal portion 1a and a pair of skirts 1b depending downward from the two sides of the horizontal portion 1a to leave a recess at the lower side; a track base 2 having its upper portion fitted in the recess of the sliding bed 1 at a predetermined gap inbetween; a pair of covers 3 attached to the front and rear end faces of the sliding bed 1; and a number of balls 4 rolling between the sliding bed 1 and the track base 2 while bearing the loads.

The sliding bed 1 is formed with an arcuately-curved load race 11, which is extended longitudinally along the root of the inner side of each of the skirts 1b, and a no-load ball hole 12 constituting a no-load track corresponding to the load race 11. On the other hand, the track base 2 is formed at its two shoulders with races 21 which correspond to the load races 11 of the sliding bed 1. Moreover, each of the covers 3 is formed in its inner side with a guide groove for providing the communicating connections between the load races 11 of the sliding bed 1 and the end portions of the no-load ball holes 12 to form an endless track. The aforementioned numerous balls 4 are circulated to roll in each of the endless tracks thereby to bear the loads between the load races 11 of the sliding bed 1 and the races 21 of the track base 2.

On the other hand, the inner side of each of the skirts 1b of the sliding bed 1 is formed at its leading end with the convex portion having a generally trapezoidal section composed of an upward taper surface 13 and a downward taper surface 14. Moreover, the track base 2 is formed at each of its two sides with a convex portion which is composed of such an downward taper surface 22 and an upward taper surface 23 as are matched by the aforementioned convex portion. These convex and concave portions are fitted in such a wedged manner to constitute a sliding bearing mechanism that their upward and downward taper surfaces face each other.

As shown in FIG. 5, moreover, there is interposed, between the sliding bed 1 and the table T to be mounted on the upper surface of the sliding bed 1, gap adjusting means for elastically deforming the horizontal portion 1a of the sliding bed 1. Since the gap between the sliding bed 1 and the track base 2 is adjusted by that means, the pressure of contact between the upward and downward tape surfaces 13 and 14 of the sliding bed 1 and the downward and upward taper surfaces 22 and 23 of the track base 2 can be accordingly adjusted.

In this embodiment, the gap adjusting means is constructed by forming a pair of mounting faces 15 on the upper surface of the horizontal portion 1a of the sliding bed 1 in the longitudinal direction over the two skirts 1b, by mounting the table T to the mounting faces 15 by means of the plural fastening bolts 5 while leaving the predetermined gap between the upper surface of the horizontal portion 1a and the lower side of the table T, by equipping the table T with a gap adjusting bolt or the suspending bolt 6 which is extended through the table T and fitted in a gap adjusting screw hole 16 formed in an intermediate position between the paired mounting faces 15, and by turning the suspending bolt 6 to apply the suspending force to the horizontal portion 1a of the sliding bed 1 thereby to deform the horizontal portion 1a elastically so that the gap between the sliding bed 1 and the track base 2 may be adjusted according to the elastic deformation.

Thus, according to the linear sliding bearing B of the present embodiment, the pressure of contact between the upward and downward taper surfaces 13 and 14 of the sliding bed 1 and the downward and upward taper surfaces 22 and 23 of the track base 2 can be adjusted by turning the suspending bolt 6 which is fastened in the gap adjusting screw hole 16 of the sliding bed 1, while the sliding bed 1 is being assembled with the table T, as shown in FIG. 5. If, at this time, the suspending bolt 6 is loosened, the pressure of contact between the taper surfaces of the track base 2 and the taper surfaces of the sliding bed 1 is dropped until it disappears, so that the sliding bed 1 can slide on the track base 2 with a slight sliding resistance (as shown in FIG. 8). If, on the contrary, the suspending bolt 6 is fastened, the pressure of contact between the taper surfaces of the track base 2 and the sliding bed 1 is raised to increase the frictional forces between the upward and downward taper surfaces 13 and 14 of the sliding bed 1 and the downward and upward taper surfaces 22 and 23 of the track base 2 so that a high sliding resistance is exerted when the sliding bed 1 slides on the track base 2 (as shown in FIG. 9).

Thus, in the linear sliding bearing B according to the present embodiment, the sliding resistance of the sliding bed 1 can be increased by fastening the gap adjusting bolt 6, to apply the rigidity of the axial direction of the track base 2 to the linear sliding bearing B.

In the linear sliding bearing B of the present embodiment, moreover, the degree of fastening the gap adjusting bolt 6 can be suitably adjusted to apply the rigidity of the axial direction of the track base 2, if necessary, and to adjust the level of the rigidity at will.

INDUSTRIAL APPLICABILITY

As has been described hereinbefore, according to the linear sliding bearing of the present invention, the sliding resistance when the sliding bed slides on the track base can be adjusted to apply or adjust the rigidity of the axial direction of the track base, if necessary.

Since, moreover, the sliding bearing mechanism is constructed of the convex and concave portions fitted in the wedged manner, the loads to be exerted in the radial or inversely radial direction upon the sliding bed can be auxiliarily borne. Especially when the impacting load of the radial direction is exerted upon the sliding bed, the rolling members can be prevented from being broken while protecting the load races of the sliding bed and the races of the track base.

If necessary, a high pressure of contact can be applied between the taper surfaces of the sliding bed and the taper surfaces of the track base by the gap adjusting means to exert an excessive sliding resistance to the sliding bed so that the sliding bed can be continuously fixed in a portion on the track base, whereby the sliding bearing mechanism can be acted as a lock mechanism.

I claim:

1. A linear sliding bearing comprising: a sliding bed having a section of generally inverted C-shape and including a horizontal portion and a pair of skirts depending downward from the two ends of the horizontal portion to form a recess at its lower side and formed in

its inner sides with a pair of load races extending longitudinally thereof and with relief ball tracks corresponding to the load races; a track base having its upper portion fitted in the recess of said sliding bed, while maintaining a predetermined spacing inbetween, and formed with rolling races corresponding to said load races; a pair of covers attached to the front and rear end faces of said sliding bed and formed in their inner sides with guide grooves for providing the communicating connections between the end portions of the load races and the relief ball tracks of said sliding bed to form endless ball tracks; and a multiplicity of rolling members circulating in said endless ball tracks to bear the loads between the load races of said sliding bed and the rolling grooves of said track base,

wherein the improvement resides: in that the load races of said sliding bed are formed in the inner sides and at the roots of said skirts; in that the races of said track base corresponding to the load races of said sliding bed are formed at the shoulders of said track base; in that there is formed, between each of the leading ends of the inner sides of the skirts of said sliding bed and each of the two sides of the track base facing the former, a sliding bearing mechanism which include convex and concave portions having upward taper surfaces and downward taper surfaces shaped to be fitted in a wedged manner; and in that there is interposed, between said sliding bed and a table to be mounted on the upper surface of said sliding bed, gap adjusting means which includes a suspension or pressure mechanism for elastically deforming the horizontal portion of said sliding bed, whereby the pressure of contact between the upward and downward taper surfaces of said sliding bed and the downward and upward taper surfaces of said track base is adjusted by adjusting the gap between said sliding bed and said track base by said gap adjusting means.

2. A linear sliding bearing as set forth in claim **1**, wherein said sliding bed includes a convex portion of a generally trapezoidal section having an upward taper surface and a downward taper surface at the leading end of the inner side of each of the skirts thereof, and wherein said track base includes a concave portion shaped to correspond to said convex portion and to have a downward taper surface and an upward taper surface at each of the two sides thereof.

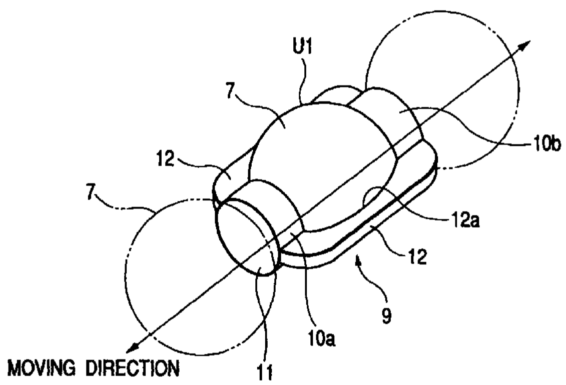
(54) **Rolling element and rectilinearly-movable apparatus using the rolling element**

(57) A rolling-element hold spacer (9) includes a spherical indent (11) which is formed in either side of a rolling element (7) so as to match the curved surface of the rolling element (7); thick hold sections (10a,10b) to be interposed between the rolling elements (7); and thin bent sections (12) for interconnecting only one thick hold section pair (10a,10b) in which the rolling element (7) is to be interposed. The thin bent section (12) is deflected or twisted in a curved portion of a rolling-element circulation path. Further, the rolling-element hold spacers which are adjacent to each other with a single rolling element interposed therebetween mutually perform pivotal movement around the rolling element (7), thereby enabling smooth circulation of the rolling elements (7). Clearance arises between the rolling element (7) and the thick hold sections (10a,10b) as a result of bent of the thin bent section (12). Lubricant enters the clearance, to thereby sufficiently lubricate the rolling elements (7). So long as a rolling-element hold spacer (9) is placed around every other rolling element (7), all the rolling elements (7) are eventually held by the rolling-element hold spacers (9). Consequently, the number of rolling-element hold spacers (9) can be reduced to one-half the number of the rolling elements (7), and the number of rolling elements (7) can be increased correspondingly.

FIG. 2A



EP 1 024 305 A2

Description

BACKGROND OF THE INVENTION

1. Field of the Invention

[0001] The present invention relates to a rolling-element hold spacer for retaining, in a rotatable and slidable manner, rolling elements used in a rectilinearly-movable apparatus, such as a rectilinearly-rolling guide apparatus, a ball screw, and a ball spline, as well as a rectilinearly-movable apparatus using the rolling element hold spacer.

2. Description of the Related Art

[0002] As shown in FIG. 15, a single-element retainer 2 for individually holding a ball 1 has already been known as a rolling-element hold spacer for a holding ball (corresponding to a rolling element) used in a rectilinearly-movable apparatus (see, for example, Japanese Patent Publication No. 33774/1993). The ball 1 is held, in a rotatable and slidable manner, within a housing hole 2a formed in the single-element retainer 2 while the upper and lower portions of the ball 1 are partially exposed. The single-element retainer 2 is incorporated in the rectilinearly-movable apparatus. A fittingly-insert section 2b is bulgily formed in the single-element retainer 2 on either side of the ball 1 and is to be inserted into a guide channel formed in a slide member. The single-element retainers 2, each housing the ball 1, are inserted in a circulation path of the slide member. The single-element retainers 2 travel in the direction designated by A shown in the drawing. The opposite ends of the single-element retainer 2, which come into contact with the corresponding ends of the adjoining single-element retainers 2 while the single-element retainers 2 are traveling along the circulation path, are formed so as to assume a circular-arc shape 2c. The distance between the centers of the adjacent balls 1 is maintained constantly. Since the balls 1 are arranged and held in a circulation path while being held by the respective single-element retainers 2, the balls 1 are prevented from rubbing against each other during circulation, thus preventing generation of a collision sound or abrasion, which would otherwise be caused by rubbing action.

[0003] Such a known single-element retainer 2 is suitable for being arranged and housed in the circulation path of the rectilinearly-rolling guide apparatus, as well as for effecting two-dimensional change between linear travel direction A and U-shaped travel direction B, as shown in FIG. 15. However, there may be a case where a ball screw requires three-dimensional change of direction and torsional movement with respect to a travel direction, as well as two-dimensional change of direction. The single-element retainer 2 is difficult to effect such complicated movements. Further, the circumference of the ball 1 exclusive the upper and lower portions thereof is covered with the single-element retainer 2. It is difficult for a lubricant to enter the space between the single-element retainer 2 and the ball 1, thus insufficiently lubricating the ball 1. Further, since one single-element retainer 2 is used for holding a single ball 1, space for the circular-arc portions 2c of the adjacent single-element retainers 2 must be ensured between the adjacent balls 1. For this reason, the single-element retainers 2 occupy space within the circulation path, thus imposing a limitation on the number of balls 1 to be inserted into the circulation path. Therefore, the rectilinearly-rolling guide apparatus cannot assume a large load-carrying capacity. The portion of the single-element retainer 2 which comes into contact with the corresponding portion of the adjacent single-element retainer 2 assumes a circular-arc protrudent shape 2c, and hence the adjacent single-element retainers 2 come into substantial line contact with each other, thus increasing a contact pressure. Consequently, there is a case where the single-element retainers 2 repeatedly come into collision with each other during the course of circulating operation, thus causing a collision sound. Further, the single-element retainer 2 has the bulgily-formed fittingly-insert sections 2b and hence has an irregular thickness with respect to the circulating direction of the single-element retainer 2 (i.e., direction A). Therefore, the single-element retainers 2 may cause pitching during a circulating operation.

SUMMARY OF THE INVENTION

[0004] Accordingly, the present invention is aimed at providing a rolling-element hold spacer which ensures smooth circulating operation even in the case of a complicated movement mode such as that effected in a three-dimensional change-of-direction path and which can increase the load-carrying capacity of a rectilinearly-movable apparatus by means of increasing the number of rolling elements inserted in a circulation path.

[0005] Also, the present invention is aimed at providing a rectilinearly-movable apparatus equipped with the rolling element hold spacer.

[0006] To achieve the above objects, according to a first aspect of the invention, there is provided a rolling-element hold spacer comprising:

> a thick hold section having spherical indents formed on both sides thereof, said thick hold sections being adapted to be interposed between rolling elements so that the spherical indents match the curved surface of the rolling elements; and
> thin bent sections for interconnecting only one thick hold section pair in which the rolling element is to be interposed.

[0007] In the first aspect of the present invention, the thin bent section is deflected or twisted in a curved portion of a rolling-element circulation path. Further, the rolling-element hold spacers which are adjacent to each other with a single rolling element interposed therebetween mutually perform pivotal movement around the rolling element, thereby enabling smooth circulation of the rolling elements. Clearance arises between the rolling element and the thick hold sections as a result of bent of the thin bent section. Lubricant enters the clearance, to thereby sufficiently lubricate the rolling elements. So long as the rolling-element hold spacer is placed every other the rolling elements, all the rolling elements are eventually held by the rolling-element hold spacers. Consequently, the number of rolling-element hold spacers can be reduced to one-half the number of the rolling elements.

[0008] More specifically, the number of rolling-element hold spacers to be inserted into the rolling-element circulation path is reduced, and the number of rolling element can be increased correspondingly. As a result, the load-carrying capacity of a rectilinearly-movable apparatus employing the rolling-element hold spacers can be increased. Further, the thick hold sections of the rolling-element hold spacer hold the rolling element by way of the spherical indents, and hence a contact pressure developing between the rolling-element hold spacer and the rolling element can be diminished. Accordingly, there can be prevented generation of a collision sound, which would arise during the circulation of the rolling elements, thus enabling smooth circulation of the rolling elements. The thin bent section interconnecting the thick hold sections has a strip shape and a uniform thickness in the traveling direction of the rolling-element hold spacer. So long as the width of a guide groove formed in the slide member for the purpose of guiding the thin bent section is set to be slightly greater than the thickness of the thin bent section, the rolling-element hold spacer is stably guided without involvement of a pitching problem, thus ensuring smooth circulation of the rolling elements.

[0009] Preferably, the thin bent section is provided on either side of the rolling element.

[0010] By means of such a configuration of the present invention, the thin bent section provided on either side of the rolling element stably holds the rolling element, thus prolonging the life of the rolling-element hold spacer.

[0011] Preferably, the thin bent section is provided only on one side of the rolling element.

[0012] By means of such a configuration of the present invention, even when the rolling elements are circulated through a warped circulation path, the thin bent section can be freely deflected so as to match the warped path. Therefore, the rolling elements can be smoothly circulated in the circulation path.

[0013] Also, according to a second aspect of the invention, there is provided a rectilinearly-movable apparatus comprising:

a track shaft having rolling-element travel surfaces;

a slide member having load travel surfaces corresponding to the rolling-element travel surfaces and attached to said track shaft so as to freely perform movement relative thereto;

a plurality of rolling elements arranged and housed in the rolling-element travel circulation path and are circulated in association with the movement of said slide member relative to said track shaft; and

a plurality of rolling-element hold spacers, each of which rotatively holds each of the rolling elements;

wherein said rolling-element hold spacer comprises a thick hold section having spherical indents formed on both sides thereof, said thick hold sections being adapted to be interposed between rolling elements so that the spherical indents match the curved surface of the rolling elements; and thin bent sections for interconnecting only one thick hold section pair in which the rolling element is to be interposed.

[0014] As mentioned above, in the present invention, so long as the rolling-element hold spacer is placed every other the rolling elements, all the rolling elements are eventually held by the rolling-element hold spacers. Consequently, the number of rolling-element hold spacers can be reduced to one-half the number of the rolling elements. More specifically, the number of rolling-element hold spacers to be inserted into the rolling-element circulation path is reduced, and the number of rolling elements can be increased correspondingly. As a result, the load-carrying capacity of a rectilinearly-movable apparatus employing the rolling-element hold spacers can be increased. Further, particularly in a warped portion of the rolling-element circulation path, the thin bent section is deflected, thus making smooth circulation of the rolling elements. Clearance is arises between the rolling element and the thick hold sections as a result of bent of the thin bent section. Lubricant enters the clearance, to thereby sufficiently lubricate the rolling elements.

BRIEF DESCRIPTION OF THE DRAWINGS

[0015]

FIG. 1 is a perspective view showing a rectilinearly-rolling guide apparatus having incorporated therein a ball hold spacer according to a first embodiment of the present invention;

FIGs. 2A to 2C show a ball hold spacer of the first embodiment, wherein FIG. 2A is a perspective view showing the ball hold spacer, FIG. 2B is a side view showing the same, and FIG. 2C is a plan view showing the same;

FIGs. 3A to 3C show the rectilinearly-rolling guide apparatus, wherein FIG. 3A is a cross-sectional view taken in the direction perpendicular to the axial direction of a rail and FIGS. 3B and 3C are enlarged views showing a load travel path;

FIG. 4 is a cross-sectional view which is taken in the axial direction of the rail and shows circulation of balls within a ball circulation path;

FIGs. 5A and 5B show a ball hold spacer according to a second embodiment of the present invention, wherein FIG. 5A is a perspective view showing the ball hold spacer and FIG. 5B is a plan view showing the same;

FIGs. 6A to 6C show a rectilinearly-rolling guide apparatus having incorporated therein the ball hold spacer of the second embodiment, wherein FIG. 6A is a cross-sectional view taken in the direction perpendicular to the axial direction of the rail and FIGS. 6B and 6C are enlarged views showing a load travel channel;

FIG. 7 is a perspective view showing a ball screw having incorporated therein the ball hold spacer of the second embodiment;

FIG. 8 is a perspective view showing a return pipe provided in the ball screw shown in FIG. 7;

FIG. 9 is a side view showing a return pipe, a screw shaft, and balls, which correspond to the principal elements of the balls screw shown in FIG. 7;

FIG. 10 is an operation diagram showing raising of a ball within the return pipe shown in FIG. 8;

FIGs. 11A and 11B show the movement of the ball hold spacer when the ball hold spacer changes direction, wherein FIG. 11A is a perspective view showing a deflected state of a thin bent section and FIG. 11B is a perspective view showing mutual pivotal movement arising between the ball hold spacers;

FIG. 12 is a perspective view including a partial cross section of a ball screw of deflector type to which the ball hold spacer of the present invention is applied;

FIG. 13 is a cross-sectional view which shows the principal section of the ball screw shown in FIG. 12 and is taken in the direction perpendicular to the axial direction of a screw shaft;

FIG. 14 is an illustration of the ball screw when viewed in direction G-G shown in FIG. 13; and

FIG. 15 is a perspective view showing a single retainer which serves as a known rolling-element hold spacer.

DETTAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

[0016] Now, a description will be given in more detail of preferred embodiments of the present invention with reference to the accompanying drawings.

[0017] FIG. 1 shows a rectilinearly-rolling guide apparatus 5 incorporating a ball-retaining spacer as a rolling-element hold spacer according to a first embodiment of the present invention. The rectilinearly-rolling guide apparatus 5 guides a movable member, such as a table, on a stationary section, such as a bed or a saddle. The rectilinearly-rolling guide apparatus 5 is placed on the stationary section and includes a guide rail 8 (serving as a "track spindle"); a movable block (slide member) 6; and a plurality of balls 7. Ball travel grooves 8a, each serving as a ball rolling surface, are formed in the guide rail 8 in the longitudinal direction thereof. A ball circulation path (i.e., a rolling-element circulation path) including load travel grooves 6a, which serve as load rolling surfaces and correspond to the respective ball travel grooves 8a of the guide rail 8, is formed in the movable block 6. The movable block 6 is also attached to the guide rail 8 so as to cause relative movement with respect to the guide rail 8. The balls 7 serve as rolling elements which are to be arranged and housed within the ball circulation path and which are circulated in association with the movement of the movable block 6 relative to the guide rail 8. In association with infinite circulation of the balls 7, the movable block 6 supporting a movable member is linearly moved along the guide rail 8.

[0018] FIGS. 2A to 2C show a ball hold spacer 9 serving as a rolling-element hold spacer to be incorporated into the rectilinearly-rolling guide apparatus 5. The ball hold spacers 9 are placed such that a single ball hold spacer 9 is provided in every other balls 7 and hold, in a rotatable and sliding manner, the plurality of balls 7 rotating between the movable block 6 and the guide rail 8. Each of the ball hold spacers 9 has thick hold sections 10a and 10b, which are to be placed between the balls 7 that are arranged in a row. The thick hold sections 10a and 10b are formed so as to assume a substantially cylindrical shape. Further, the outer diameter of the thick hold section 10a and the outer diameter of the thick hold section 10b are set to be smaller than the diameter of the ball 7. A spherical indent 11 is formed in either side of the thick hold section 10a so as to correspond to the ball 7 with respect to the axial direction thereof. Similarly, the spherical indent 11 is formed in either side of the thick hold section 10b so as to correspond to the ball 7 with respect to the axial direction thereof. The spherical indent 11 is formed as a curved-surface indent whose curvature radius is substantially identical with the radius of the ball 7. When the ball hold spacer 9 is placed between the balls 7, the axis of the thick hold section 10a and the axis of the thick hold section 10b are brought into line with an extension of an imaginary line interconnecting the centers of the balls 7. As shown in FIG. 2B, the axial width of the thick hold section 10a and the axial width of the thick hold section 10b are set to a small value, as indicated by W, thus shortening the distance between the balls 7. An oil reservoir hole may be formed in the center of the spherical indent 11 as a lubricant hold section which penetrates the thick hold sections 10a and 10b in the axial direction.

[0019] A thick hold section pair which comprises the thick hold sections 10a and 10b and is placed so as to sandwich the ball 7 therebetween is formed by interconnecting the thick hold sections 10a and 10b by means of strip-shaped thin bent sections 12. The thin bent section 12 has a uniform thickness and interconnects one side surface of the thick hold section 10a and the corresponding side surface of the thick hold section 10b while extending across the ball 7 placed therebetween. The portion of the thin bent section 12 which is to interfere with the ball 7 is formed into a recessed section 12a whose curvature radius is substantially equal to the radius of the ball 7. Corners formed on the opposite longitudinal ends of the thin bent section 12 are formed into round corners 12b (see FIG. 2C). The thin bent sections 12 are placed on opposite sides of the ball 7 so as to constitute a single plane. The thick hold sections 10a and 10b and the thin bent section 12 are formed integrally from synthetic resin or a like material by means of injection molding.

[0020] As shown in FIGS. 1 and 3, the guide rail 8 has an elongated shape and a substantially-rectangular cross section. As mentioned above, the ball travel groove 8a, acting as a track along which the balls 7 roll, is formed on either longitudinal side of the guide rail 8 so as to extend over the entire length of the guide rail 8. Although the illustrated guide rail 8 has a linear geometry, two ball travel grooves 8a are formed in either side of the guide rail 8 (i.e., a total of four ball travel grooves 8a are formed), the number of ball travel grooves may be changed variously according to the purpose of the rectilinearly-rolling guide apparatus 5.

[0021] The movable block 6 is substantially constituted by connecting a movable main unit 13 to a pair of side covers 14 provided on the opposite ends thereof, by means of bolts. Four load travel grooves 6a are formed in the movable main unit 13 so as to correspond to the respective ball travel grooves 8a. Four load travel channels C are formed between the guide rail 8 and the movable block 6, by combination of the load travel grooves 6a and the ball travel grooves 8a. Four return channels D-which extend in parallel with the load travel channels C-and change-of-direction channels for connecting the return channels D with the load travel channels C are formed in the movable block 6. A single ball circulation path is formed by combination of the load travel channel C, the return channel D, and the direction-of-change channel interconnecting the load travel channel C and the return channel D.

[0022] As shown in FIG. 3, the movable main unit 13 comprises a main unit block 16 and molded bodies 17a and 17b. The main unit block 16 is a highly-ridge structural body which is formed from steel or like material so as to be able to bear the load imposed on the movable block 6. Screw holes are formed in the upper surface of the main unit block 16 for securing an object which is to be guided by the rectilinearly-rolling guide apparatus 5. The molded bodies 7a and 7b are molded integrally with the main unit block 16 by means of injecting resin melt into a mold in which the main unit block 16 is placed; that is, by means of a so-called insert molding technique. The molded bodies 17a and 17b may be formed by means of die-cast molding while metal, such as aluminum, is used in place of resin. Further, the movable main unit 13 may be assembled not only by means of insert molding but also by means of assembly of the main unit block 16 and the molded bodies 17a and 17b, which are formed separately. Alternatively, the main unit block 16 and the molded bodies 17a and 17b may be formed integrally with each other by means of metal injection molding (MIM).

[0023] As shown in FIGS. 3 and 4, the above-mentioned load travel grooves 6a are formed in the main unit block 6, and the return channels D are formed in the molded body 17a. Four through holes extending in parallel with the load travel channels 6a are formed in the main unit block 16. Tube-like sections of the molded body 17a are formed integrally with the through holes. The return channel D for returning the balls 7 and a guide grove 18 for guiding the thin bent sections 12 are formed in the tube-like section of the molded body 17a. A pair of ball hold sections 19 are formed in each of the areas of the molded body 17b opposing the load travel channels C such that the load travel channel 6a is interposed between the ball hold section pair 19. When the movable block 6 is removed from the guide rail 8, the ball hold section pair 19 prevents dislodging of the balls 7 from the load travel channels C. The thin bent sections 12 are guided through the space defined between the ball hold section pairs 19 and the main unit block 16 (see FIGS. 3B and 3C).

[0024] In the ball circulation path constituted of the load travel channel C, the change-of-direction channel E, and the return channel D, the width of the guide groove 18 for guiding the thin bent section 12 is maintained at a constant width slightly greater than the thickness of the thin bent section 12. The horizontal center of the guide groove 18 is displaced toward the main unit block 16 from the horizontal center of track along which the balls 7 travel, by only X. As a result, the curvature radius of the change-of-direction section of the ball circulation path can be made small, thus making the rectilinearly-rolling guide apparatus 5 compact.

[0025] As shown in FIG. 4, each of the molded bodies 17a comprises arch-shaped inner radius sections 17c which protrude from the opposite ends of the main unit block 16. In each of the side covers 14, there are formed outer radius sections 14a, each of which constitutes the change-of-direction channels E together with the inner radius section 17c formed in the corresponding molded body 17a. When the side covers 14 are attached to the main unit block 16, the inner radius guide section 17c and the outer radius guide section 14c in combination constitute the change-of-direction channel E. Further, as a result of combination of the inner radius guide section 17c with the outer radius guide section 14c, the guide groove 8 for guiding the thin bent sections 12 is also formed in the change-of-direction channel E.

[0026] The ball 7 is fitted into the space defined between the thick hold sections 10a and 10b of the ball hold spacer 9, thus forming one unit U1 (see FIGS. 2A and 4). At this time, the ball 7 is held in the ball hold spacer 9 so as to be freely rotatable. The units U1 and the balls 7 are alternately inserted into the ball circulation path while the thin bent sections 12 of the ball hold spacer 9 are fitted into the guide groove 18. In association with the movable block 6 traveling along the guide rail 8, the balls 7 travel the load travel channel C from one end to the other end thereof while undergoing the load imposed by the movable block 6. Subsequently, the balls 7 enter one of the change-of-direction channels E and are guided to the return channel D. The balls 7 are then returned to one end of the load travel channel C by way of the other change-of-direction channel E. Since the thin bent section 12 of the ball hold spacer 9 is moved along the ball circulation path along a track defined by the guide groove 18, the balls 7 held in the ball hold spacers 9 are orderly circulated in the ball circulation path without involving a snaking action.

[0027] As mentioned above, the ball hold spacer 9 is placed in every other balls 7, and the ball 7 is held in the space of the thick hold sections 10a and 10b which forms a pair. The ball 7 which is not held in the ball hold spacer 9 is retained between the adjacent ball hold spacers 9 such that one side of the ball 7 is in contact with either the thick hold section 10a or 10b of one adjacent ball hold spacer 9 and the other side of the same is in contact with a thick hold section of another adjacent ball hold spacer 9 which is to oppose the thick hold section 10a or 10b of the one adjacent ball hold spacer 9. As mentioned above, so long as the ball hold spacer 9 is placed in every other balls 7, all the balls 7 are eventually retained by the ball hold spacers 9. Consequently, the number of the ball hold spacers 9 can be reduced to one-half the balls 7. More specifically, the number of ball hold spacers 9 to be inserted into the ball circulation path is reduced, and the number of balls 7 can be increased correspondingly. Consequently, the load-carrying capacity of the rectilinearly-rolling guide apparatus 5 can be increased. Further, the ball 7 is retained between the spherical indent 11 formed in the thick hold section 10a and the spherical indent 11 of the thick hold section 10b, thus reducing the contact pressure developing between the ball hold spacer 9 and the ball 7. As a result, there is reduced a collision sound, which would arise during the circulation of the balls 7, whereby the balls 7 are circulated smoothly.

[0028] The thin bent section 12 is set to have a uniform thickness in the traveling direction thereof, and the width of the guide groove 18 for guiding the thin bent section 12 is set to be slightly greater than the thickness of the thin bent section 12. Accordingly, the ball hold spacers 9 are guided stably without occurrence of pitching. In the change-of-direction section E, the guide groove 18 for guiding the thin bent section 12 is also curved into a circular-arc shape in parallel with the change-of-direction channel E. Therefore, the thin bent sections 12 are also moved on a curved path along the guide groove 18, and a clearance can be formed between the ball 7 and the thick hold sections 10a and 10b in the change-of-direction channel E. Lubricant enters the clearance, thus sufficiently lubricating the balls 7.

[0029] In the rectilinearly-rolling guide apparatus 5 of the present embodiment, the ball hold spacers 9 change direction two-dimensionally at the time of circulation of the balls 7. More specifically, the direction of the ball hold spacers 9 is changed by way of the route comprising the linear load travel channel C, the U-shaped change-of-direction channel E, the linear return channel D, and the U-shaped change-of-direction channel. As is evident from FIG. 4, since the thin bent section 12 of the ball hold spacer 9 is freely bent, smooth circulation of the balls 7 is ensured.

[0030] Although in the present embodiment the movable block 6 performs linear movement relative to the guide rail 8, the present invention can also be applied to and is suitable for use with a guide apparatus configured so as to cause curved relative movement.

[0031] FIG. 5 shows a ball hold spacer 20 according to a second embodiment of the present invention. The ball hold spacer 20 is formed from the same material as that from which the ball hold spacer 9 of the first embodiment is formed. Even with regard to configuration, the ball hold spacer 20 is placed between the balls 7 aligned in a row in the same manner as is the ball hold spacer 9. Further, the ball hold spacer 20 has thick hold sections 22a and 22b, as in the case of the ball hold spacer 9. The thick hold sections 22a and 22b are formed into a substantially cylindrical shape, and the outer diameter of the thick hold sections 22a and 22b is set to be smaller than the diameter of the ball 7. A spherical indent 23 is formed so as to correspond to the ball 7 in either side of the thick hold section 22a with respect to its axial direction. The spherical indent 23 is formed so as to correspond to the ball 7 in either side of the thick hold section 22b with respect to its axial direction. The spherical indent 23 has a curvature radius substantially equal to the radius of the ball 7. The thickness of the thick hold section 22a and the thickness of the thick hold section 22b with respect to the axial direction thereof are set to be a small value, thus shortening the distance between the balls 7 (see FIG. 5B). The thick hold sections 22a and 22b, which constitute a pair, are interconnected by means of a strip-shaped thin bent section 21. In comparison with the ball hold spacer 9 of the first embodiment, the ball hold spacer 20 of the second embodiment has a single thin bent section 21 provided on only one side of the ball 7. The thin bent section 21 has a uniform thickness and interconnects the side surface of the thick hold section 22a and the side surface of the thick hold section 22b. A notch 21a whose curvature radius is substantially equal to the radius of the ball 7 is formed in an area of the thin bent section 21 which would interfere with the ball 7. Further, either longitudinal end of the thin bent section 21 is rounded into a round corner 21b.

[0032] As shown in FIG. 5, an overhanging section 22a1 is provided in an area on the side surface of the thick hold section 22a opposite to the side surface where the end of the thin hold section 21 is attached, with respect to the diameter of the thick hold section 22a. Similarly, an overhanging section 22b1 is provided in an area on the side surface of the thick hold section 22b opposite to the side surface where the end of the thin hold section 21 is attached, with respect to the diameter of the thick hold section 22b. The overhanging sections 22a1 and 22b1 extend outwardly. Such a configuration ensures holding of the ball 7 even when there is used only the single thin bent section 21.

[0033] FIG. 6 shows a rectilinearly-rolling guide apparatus 25 having incorporated therein the ball hold spacer 20 of the second embodiment. Even in the rectilinearly-rolling guide apparatus 25, a movable block 26 is supported on a guide rail 27 by way of the plurality of balls 7. A total of four ball travel channels 27a along which the balls 7 will travel are formed in the guide rail 27 so as to extend over the entire length thereof; specifically, two ball travel channels 27a being formed in the upper surface of the guide rail 27 and one ball travel channel 27a being formed in either side of the same.

[0034] Four load travel channels 26a are formed in the movable block 26 so as to correspond to the respective ball travel channels 27a. The load travel channels 26a and the ball travel channels 27a in combination constitute four load travel channels C between the movable block 26 and the guide rail 27. Further, a guide groove 28 for guiding the thin bent section 21 is formed in each of the load travel channels 26a (see FIGS. 6B and 6C). The width of the guide groove 29 is set to be slightly greater than the thickness of the thin bent section 21.

[0035] Four through-holes are formed in the movable block 26 so as to extend in parallel with the load travel channels 26a, and a tube-like section of a molded body is formed integrally with each of the through-holes. The return channel D for returning the balls 7 and the guide groove 28 for guiding the thin bent section 21 are formed within the tube-like section. The width of the guide channel 28 is also set to be slightly greater than the thickness of the thin bent section 21. The guide grooves 28 and 29 are formed in only the inner radius side of the ball circulation path.

[0036] The thin bent section 21 has a strip-shaped profile and is set to have a uniform thickness in the traveling direction thereof, and the width of the guide groove 18 for guiding the thin bent section 21 is set to be slightly greater than the thickness of the thin bent section 21. Accordingly, the ball hold spacers 20 are guided stably without occurrence of pitching. Further, the thin bent section 21 is provided on only one side of the ball 7, thus enabling free bent of the ball hold spacer 20. Accordingly, the ball hold spacers 20 and the balls 7 are smoothly circulated not only when the ball hold spacers 20 and the balls 7 are circulated along a two-dimensionally-warped change-of-direction channel but also when the ball hold spacers 20 and the balls 7 are circulated along a three-dimensionally-warped change-of-direction channel. Such a configuration is suitable for use with a twisted circulation path or a circulation path involving a sharp change in direction; for example, a ball screw and a nut thereof. As in the case of the ball hold spacer 9 of the first embodiment, in a case where the thin bent section 12 is provided on either side of the ball 7, the balls 7 are held stably, and the life of the ball hold spacer 20 becomes longer. Further, in a case where the radius of the cross section of the ball travel channel 26a is set to be greater than the radius of the ball 7, the balls 7 that are being circulated may cause a swinging action in the widthwise direction of the ball travel channel 26a (in direction Y shown in FIGS. 6B and 6C). In this case, since the guide grooves 28 and 29 are formed in along the inner radius side of the circulation path, the thin bent section 21 is prevented from undergoing repeated expanding and contracting action. Thus, the thin bent section 21 can be prevented from being susceptible to fatigue.

[0037] FIG. 7 shows a ball screw 30 having incorporated therein the ball hold spacers 20 of the second embodiment. The ball screw 30 comprises a screw shaft 31 (corresponding to a "track spindle"), a nut member 32 (corresponding to a "slide member"), and a plurality of balls. A ball travel channel 31a serving as a rolling-element travel surface is helically formed in the exterior circumferential surface of the screw shaft 31. A ball circulation path (corresponding to a "rolling-element circulation path") is formed in the interior circumferential surface of the nut member 32 so as to include a load travel channel 32a which serves as a load travel surface and is helically formed so as to correspond to the ball travel channel 31a. The nut member 32 is attached to the screw shaft 31 so as to be able to cause movement relative thereto. The balls serve as rolling elements and are circulated through the ball circulation path in association with the relative movement (rotation) arising in between the screw shaft 31 and the nut member 32. The load travel channel of the ball circulation path is defined between the ball travel channel 31a of the screw shaft 31 and the load travel channel 32a of the nut member 32. The nut member 32 has two return pipes 36, and the return pipe 36 constitutes a no-load return channel which connects one end and the other end of the load travel channel. As shown in FIGS. 8 and 9, either end of the return pipe 36 is folded toward the screw shaft 31, and both ends of the return pipe 36 are fitted into the load travel channel so as to be spaced at several pitches apart from each other. Further, the return pipes 36 are secured to the nut member 32 by means of a pipe presser 34 (see FIG. 7).

[0038] The ball travel channel 31a formed in the screw shaft 31 is formed so as to assume; for example, a circular-arc cross section, by means of grinding or rolling.

[0039] As shown in FIG. 7, the main unit of the nut member 32 has a substantially cylindrical shape, and a flange 35 to be connected to a corresponding component is provided at one end of the nut member 32. A flat-face section 40 is formed in the nut member 32 by removal of a portion of the exterior circumference of the nut member 32 by means of machining. Four return pipe fitting holes 41 are formed in the flat-face section 40, and the respective ends of the return pipes 36 are fitted into the return pipe fitting holes 41. The return pipe fitting hole 41 extends to the inside of the load travel channel 32a.

[0040] As is evident from FIG. 8, the return pipe 36 has a circular cross section, and either end portion of the return pipe 36 is bent at an angle of about 90° with respect to the nut member 32. Specifically, the return pipe 36 is formed into a substantially arch-shaped form and comprises a pair of legs 36a and 36b and a horizontal portion 36c interconnecting the legs 36a and 36b. As illustrated in the drawing, the legs 36a and 36b are not in parallel with each other and are twisted so as to form a torsional angle $\theta 1$ (which changes in accordance with a lead angle). A guide groove 37 is formed in the interior surface of the return pipe 36 so as to extend in the axial direction and over the entire length of the return pipe 36. The width of the guide groove 37 is set to be slightly greater than the thickness of the thin bent section 21. Both ends of the return pipe 36; that is, the legs 36a and 36b, are obliquely cut into cuts 38. The width of the cut 38 is gradually narrower with respect to the depthwise direction of the return pipe 36.

[0041] FIG. 9 shows the balls 7 and the ball hold spacers 20, which are to be inserted into the load travel channel and the return pipes 36. This drawing shows only the ball hold spacers 20 which can be viewed in cross section, and the other rolling-element hold spacers are omitted from the drawing. The ball hold spacer 20 is placed in every other balls 7, and the ball 7 is retained in one thick hold section pair comprising the thick hold sections 10a and 10b. The ball 7 that is not housed in the ball hold spacer 20 is held between the thick hold sections 10a and 10b of the adjacent ball hold spacers 20 which mutually oppose. So long as the spherical indent 23 of the ball hold spacer 20 is formed so that the ball hold spacers 20 and the balls 7 can be arranged in substantially an annular pattern, there can be prevented application of undue force to the ball hold spacers 20 and the balls 7, which would otherwise be caused during circulation of the ball hold spacers 20 and the balls 7.

[0042] As shown in FIG. 9, a guide groove 33 to be used for guiding the thin bent section 21 of the ball hold spacer 20 is formed in a ball travel channel 32a of a nut member 32. The guide groove 33 is helically formed so as to run along the ball travel channel 32a of the nut member 32, and the width of the guide groove 33 is set to be slightly greater than the thickness of the thin bent section 21. Further, the guide groove 33 is formed so as to protrude outward from a row of balls 7 arranged in an annular pattern.

[0043] FIG. 10 shows a change in the cross-sectional shape of each of the legs 36a and 36b of the return pipe 36. Reference numeral 0 designates the cross-sectional view of the tip end of the leg, and cross-sectional views designated by reference numerals 1 through 9 are taken progressively toward a deeper and inner portion of the return pipe 36. As illustrated in the drawing, in the cross-sectional view designated by 0, the cross section of each of the legs 36a and 36b assumes a substantially semi-circular shape whose both ends slightly exceed beyond the center line D by only size "h." The cross-section of each of the legs 36a and 36b becomes closer to a circular cross section toward a deeper and inner portion of the return pipe 36 (i.e., when the ball 7 travels from position 1 to position 10), and distance W between the inner edges of the cuts 38 becomes gradually smaller. In the cross-sectional views designated by 0 through 4, the distance W between the cuts 38 is greater than the diameter of the ball 7. Thus, the ball 7 is not raised by the cuts 38 and can be rolled around the screw shaft 31. However, when the ball 7 travels from position 0 to position 4, a clearance 39 formed between the interior surface of each of the legs 36a and 36b and the surface of the ball 7 opposing the interior surface becomes slightly greater. When the ball 7 travels further upward to position 5, the opposite ends of the ball 7 start to be raised by the cuts 38. Since the distance W between the cuts 38 is gradually smaller toward an inner and deeper portion of the return pipe 36, the ball 7 is guided by the cuts 38 from position 6 to position 10 and is introduced into the return pipe 36 having a circular cross section.

[0044] As shown in FIG. 9, when the screw shaft 31 is rotated, the balls 7 which are rolled under load along the inside of the ball travel channel 31a in the circumferential direction are raised by the tip end of the leg 36a. The thus-raised balls 7 pass through the return pipe 36 and return to the ball travel channel 31a from the leg 36b which is spaced several pitches apart from the leg 36a. When the screw shaft 31 is rotated reversely, the balls 7 are circulated along the above-described path in a reverse direction. The balls 7 are circulated in the same manner in a case where the nut member 32 is rotated while the screw shaft 31 is secured.

[0045] The load travel channel of the ball screw 30 is helically formed, as mentioned previously. Further, the return pipe 36 changes the direction of the balls 7 which are raised by the tip end of the return pipe 36. As has been described by reference to FIG. 8, the return pipe 36 is twisted with respect to the traveling direction of the ball 7 (at torsional angle $\theta 1$). In the ball screw 30, the balls 7 and the ball hold spacers 20 three-dimensionally change direction and move in a complicated manner.

[0046] The ball hold spacer 20 is optimal for performing such a complicated movement.

[0047] As shown in FIG. 11A, the thin bent section 21 of the ball hold spacer 20 can be considerably, freely bent within a virtual plane 50 extending in the thicknesswise direction of the thin bent section 21. In the drawing, an angle through which the thin bent section 21 can be bent is designated by θ2. Further, the thin bent section 21 can also be bent slightly in the direction perpendicular to the virtual plane 50 and can be twisted with respect to the traveling direction of the ball hold spacer 20. In the drawing, in a case where a front end section 21d of the thin bent section 21 with respect to the traveling direction thereof is at right angles to the virtual plane 50, reference symbol θ3 designates an angle formed between the virtual plane 50 and a virtual plane 51 to which a rear end section 21e of the thin bent section 21 with respect the traveling direction thereof is at right angles.

[0048] As shown in FIG. 11B, the ball hold spacers 20 that are consecutively arranged are separated from one another and are not continuous. The ball hold spacers 20 are pivotable relative to one another within a virtual plane 52 perpendicular to the virtual plane 50. In the drawing, a relative pivotable angle between the ball hold spacers 20 is designated by θ4. In a case where the rolling element corresponds to a ball, the ball hold spacers 20 are pivotable relative to one another in every direction within the virtual plane 52. In a case where the rolling element corresponds to a roller, the ball hold spacers 20 can be pivotable within only the virtual plane 52, and a limitation is imposed on the mutual pivotable movement of the ball hold spacers 20 in another direction.

[0049] By means of flexible and twisting action of the thin blade section 21 as well as of mutual pivotal movement between the ball hold spacers 20, the ball hold spacers 20 and the balls 7 freely change direction three-dimensionally, thus enabling complicated movement such as that required by the ball screw 30 of the second embodiment. Such flexible and twisting action of the thin bent section 21 and the mutual pivotal movement between the ball hold spacers are also achieved by the ball hold spacer 9 of the first embodiment shown in FIGS. 1 through 4.

[0050] When the thin bent section 21 is bent, there can be formed a clearance between the ball 7 and the thick hold sections 22a and 22b. Lubricant enters the clearance, thus sufficiently lubricating the balls 7.

[0051] In the embodiment relating to the ball screw 30, the balls 7 that are rolling over the ball travel channel 31a of the screw shaft 31 are raised through use of the return pipe 36 and returned to a position spaced several pitches away from the position where the balls 7 have been raised. As shown in FIGS. 12 through 14, in another conceivable configuration, a deflector 61 for raising the balls 7 is provided on the nut member 32. The balls 7 which are rolling over the ball travel channel 31a of the screw shaft 31 are departed from the ball travel channel 31a by the deflector 61. The thus-departed balls 7 run beyond the outer diameter section of the screw shaft 31 and go back to the ball travel channel 31a by a lead angle. Although not illustrated in the drawing, there may also be employed a ball screw of so-called side cover type. Specifically, the nut member 32 comprises a nut body having formed therein a ball travel channel 32a and side covers attached to the respective ends of the nut body. The ball travel channel 32a and a communication channel interconnecting the return channels are formed in each of the side covers.

[0052] The ball screw equipped with the deflector 61 will now be described in detail by reference to FIGS. 12 through 14. As shown in FIGS. 13 through 14, a substantially S-shaped ball return channel 61a is formed in the deflector 61, and a guide channel 61b for guiding the thin bent section 21 of the ball hold spacer 20 is longitudinally formed in the center of the ball return channel 61a. In order to enable the balls 7 which have entered the ball return channel 61a to go beyond the outer circumference of the screw shaft 31, the ball return channel 61a has the deepest recess that is formed at the longitudinal center of the deflector 61.

[0053] In the ball screw of the present embodiment, when relative rotation arises between the screw shaft 31 and the nut member 32, the balls 7 and the ball hold spacers 20 are circulated through the ball circulation path defined in the nut member 32. Next will be described in detail the configuration of the ball circulation path and the balls 7 and the ball hold spacers 20, which are circulated in the ball circulation path.

[0054] Although the ball circulation path is formed in a substantially annular pattern so as to surround the screw shaft 31, the portion of the screw shaft 31 where the deflector 61 is provided bulges outwardly with respect to the radial direction of the screw shaft 31. In FIG. 13, reference symbol R1 designates the radius of a circular path along which the center of the ball 7 moves during the course of the ball 7 rolling over the ball travel channel 31a of the screw shaft 31a; and R2 designates the radius of a circular path along which the center of the ball 7 moves during the course of the ball 7 passing through a circular-arc section bulged by the deflector 61.

[0055] When passing through the ball return channel 61a of the deflector 61 in conjunction with the ball 7, the ball hold spacer 20 goes beyond the outer diameter of the screw shaft 31 along the portion of the ball circulation path which bulges in a radially outward direction. The ball hold spacer 20 travels along an S-shaped zigzag path along the ball return channel 61a and goes back to the ball travel channel 31a by only a lead angle (designated by reference symbol R shown in FIG. 14) with respect to the axial direction of the screw shaft 31. As a result, the ball 7 and the ball hold spacer 20 go back to the ball travel channel 31a by one turn and are circulated around the screw shaft 31.

[0056] In FIG. 13, since the ball hold spacers 20 are mutually pivotable, the ball hold spacers 20 travel so as to well follow the balls 7 when the balls 7 roll such that their centers travel from radius R1 to radius R2. The thin bent section 21 of the ball hold spacer 20 is flexibly bent in the thicknesswise direction. Even in a case where the ball hold spacer 20 is guided along the S-shaped path within the deflector 61 shown in FIG. 14; that is, a case where the ball hold spacer 20 changes direction so as to have a point of inflection, the ball hold spacer 20 can smoothly pass the guide. As mentioned above, by means of free bent (and twisting action) of the thin bent section 21 and the mutual pivotal movement between the ball hold spacers 20, the ball hold spacers 20 and the balls can freely change direction three-dimensionally, thus enabling complicated movement such as that required in the present embodiment.

[0057] Even when the present invention is applied to the previously-described ball screw of side cover type, there is yielded the same advantage as that mentioned above.

[0058] The ball hold spacers 9 and 20 of the present invention can not be limited to a rectilinearly-rolling guide apparatus or a ball screw but can be applied to a ball spline machine. The term "ball spline machine" refers to a machine comprising a spline shaft serving as a track member and an outer casing which serves as a slide member and is movably attached to the spline shaft by way of a plurality of balls. Although in the previous embodiments balls are used as rolling elements, rollers can also be employed.

[0059] As has been described above, the present invention provides a rolling-element hold spacer including: a thick hold section having spherical indents formed on both sides thereof, said thick hold sections being adapted to be interposed between rolling elements so that the spherical indents match the curved surface of the rolling elements; and thin bent sections for interconnecting only one thick hold section pair in which the rolling element is to be interposed.

[0060] Even in a case where a rolling-element circulation path requires three-dimensional change in direction, the thin bent section is flexibly deflected. Further, the rolling-element hold spacers which are adjacent to each other with a single rolling element interposed therebetween mutually perform pivotal movement around the rolling element, thereby enabling smooth circulation of the rolling elements. Clearance arises between the rolling element and the thick hold sections as a result of bent of the thin bent section. Lubricant enters the clearance, to thereby sufficiently lubricate the rolling elements. So long as the rolling-element hold spacer is placed every other the rolling elements, all the rolling elements are eventually held by the rolling-element hold spacers.

[0061] Consequently, the number of rolling-element hold spacers can be reduced to one-half the number of the rolling elements. More specifically, the number of rolling-element hold spacers to be inserted into the rolling-element circulation path is reduced, and the number of rolling elements can be increased correspondingly. As a result, the load-carrying capacity of a rectilinearly-movable apparatus employing the rolling-element hold spacers can be increased. Further, the thick hold sections of the rolling-element hold spacer hold the rolling element by way of the spherical indents, and hence a contact pressure developing between the rolling-element hold spacer and the rolling element can be diminished.

[0062] Accordingly, there can be prevented generation of a collision sound, which would arise during the circulation of the rolling elements, thus enabling smooth circulation of the rolling elements. The thin bent section interconnecting the thick hold sections has a strip shape and a uniform thickness in the traveling direction of the rolling-element hold spacer. So long as the width of a guide groove formed in the slide member for the purpose of guiding the thin bent section is set to be slightly greater than the thickness of the thin bent section, the rolling-element hold spacer is stably guided without involvement of a pitching problem, thus ensuring smooth circulation of the rolling elements.

Claims

1. A rolling-element hold spacer comprising:

   a thick hold section having spherical indents formed on both sides thereof, said thick hold sections being adapted to be interposed between rolling elements so that the spherical indents match the curved surface of the rolling elements; and
   thin bent sections for interconnecting only one thick hold section pair in which the rolling element is to be interposed.

2. The rolling-element hold spacer as defined in claim 1, wherein said thin bent sections are provided on both sides of the rolling element.

3. The rolling-element hold spacer as defined in claim 1, wherein said thin bent sections are disposed on only one side of the rolling element.

4. The rolling-element hold spacer as defined in claim 1, wherein said thick hold section is substantially circular.

5. The rolling-element hold spacer as defined in claim 1, wherein the outer diameter of said thick hold section is smaller than the diameter of the rolling element.

6. A rectilinearly-movable apparatus comprising:

a track shaft having rolling-element travel surfaces;

a slide member having load travel surfaces corresponding to the rolling-element travel surfaces and attached to said track shaft so as to freely perform movement relative thereto;

a plurality of rolling elements arranged and housed in the rolling-element travel circulation path and are circulated in association with the movement of said slide member relative to said track shaft; and

a plurality of rolling-element hold spacers, each of which rotatively holds each of the rolling elements;

wherein said rolling-element hold spacer comprises a thick hold section having spherical indents formed on both sides thereof, said thick hold sections being adapted to be interposed between rolling elements so that the spherical indents match the curved surface of the rolling elements; and thin bent sections for interconnecting only one thick hold section pair in which the rolling element is to be interposed.

(54) Title: A RETAINERLESS LINEAR MOTION BEARING

(57) Abstract

A ball holder (1) for a retainerless saddle (6) having an elongated shaft (2) and a plurality of contact surfaces (3) therearound to hold steel balls (7) in cooperation with a bearing body (4) only when the saddle (6) is withdrawn from a rail (R). The shaft can be made of a hollow tube (41) or a pair of cantilever projections (52 or 62) so that the size of its cross-sectional area can be adjusted. Due to this adjustability, the size of the raceways can also be adjusted to enable to reassemble the steel balls (7) into the saddle (6) at a working site.

Title of the Invention

A Retainerless Linear Motion Bearing

Background of the Invention

A conventional linear motion bearing shown in USP 4,253,709 has a large rigidity and can sustain a heavy load at a high speed with a high accuracy. Due to those excellent properties, it has been widely used especially in a field of machine tools.

One of the main features of the linear motion bearing is that it can provide a preload in the steel balls since the diameter of the steel ball is slightly larger than that of the raceway formed between the complementary grooves of the bearing body and the rail. Due to the preload, the assembled rigidity of the structure becomes larger which, in turn, enables to attain high accuracy.

On the other hand, one of the shortcomings of the linear motion bearing is in the usage of a retainer which holds or maintains the steel balls from falling off from the bearing body when it is withdrawn out of the rail.

The shape of the retainer can be either a plate structure as shown in Figure 8 in USP 4,253,709 or a piano wire-like structure extending along the grooves as shown in USP 4,929,095.

These retainers are attached either to the bearing body or to the end caps. Because of this, the structure of the linear motion bearing becomes more complicated and more difficult to assemble a saddle from bearing body with steel balls by an automatic process.

Further, if the retainer dislocates its position, it may contact the steel balls and increases the friction. The retainer will be damaged or destroyed eventually. It also increases the cost of the linear motion bearing.

Another problem of the retainer lies in that the size of the radius of the curvature of the groove is inevitably limited due to existence of the retainer in the narrow raceway and so is the load rating.

It is well known that the retainer loses its function and becomes useless once the saddle is fit onto the rail since the steel balls are held solely by the complementary grooves.

Nevertheless, there must be a retainer since if the retainer is eliminated from the linear motion bearing, there is no way to maintain the steel balls within the bearing body of the saddle when it is withdrawn from the rail.

Yet another problem is how to fit the saddle onto the rail while maintaining the loose steel balls.

Summary of the Invention

This invention is directed to a retainer-less linear motion bearing in which a retainer is completely eliminated from a bearing body. Instead, a ball holder independent of the bearing body, or a saddle, is used only when the saddle is withdrawn from the rail to retain the steel balls within the bearing body so as to prevent them from falling off when it is withdrawn from the rail.

This invention is also directed to a method for automatically assembling a complete saddle from a bearing body, end caps, steel balls and a ball holder.

Another object of the invention is to provide an adjustable ball holder which enables to reassemble the saddle at a working site without using any special devices.

Brief Description of the Drawings

Description of the Preferred Embodiments

The first embodiment is directed to a ball holder 1 in which the raceway space formed by bearing body 4 and ball holder 1 is not adjustable.

Figure 1 illustrates a cross-sectional view of a retainerless saddle 6 with a ball holder 1 according to this invention. Figure 2 shows a perspective view of saddle 6. Figure 3 shows a perspective view of ball holder 1. The cross-section of ball holder 1 is almost identical to that of track shaft part T, which is a top part of the rail R as shown in Figures 4 and 5. Ball holder 1 is formed by elongated shaft 2 and a plurality of grooves 3... at about four corners of elongated shaft 2. The number of the grooves 3... can be two or more depending upon that of track shaft part T or that of saddle 6.

The material of shaft 2 is preferably an elastic one such as soft plastic as shown in Figure 3.

When saddle 6 is withdrawn from rail R, steel balls 7 are maintained by ball holder 1. The diameter of the raceway formed by a complementary groove 8 of bearing body 4 and a complementary grooves 3 of ball holder 1 is slightly smaller than that of a steel ball 7. Therefore, the grooves 3... of ball holder 1 are slightly compressed by steel balls 7... such that ball holder 1 is press fitted within saddle 6.

Also, since ball holder 1 is smaller than the cavity within bearing body 4 of saddle 6, in storing a plurality of saddles 6... each having ball holder 1 therein, they can be placed one upon another. Thus, the storage of a plurality of saddles 6... is very convenient and occupies less space according to this invention.

As shown in Figure 4, in order to assemble saddle 6 onto rail R, saddle 6 is held by one hand of an operator while fitting the inner opening of end cap 5 onto track shaft part T of rail R and is moved toward rail R. As saddle 6 moves leftward in Figure 4, steel balls 7... are successively held within the raceways between the complementary grooves 8... of saddle 6 and those of rail R, thus are preloaded since the diameter of each raceway is smaller than that of steel ball 7. Eventually ball holder 1 is completely removed from saddle 6 since it is stopped by the end surface of track shaft part T.

Thus, steel balls 7... are maintained between rail R and bearing body 4 without a retainer as shown in Figure 5.

In order to remove saddle 6 from rail R, ball holder 1 is first positioned at the end surface of track shaft part T. Then saddle 6 is moved rightward in Figure 4 from rail R over ball holder 1 such that steel balls 7... are successively held between the complementary grooves of saddle 6 and ball holder 1.

If shaft 2 is made of a material with a plenty of elasticity such as rubber, grooves 3 may be eliminated and instead they can be flat surfaces 3′ as shown in Figure 6.

Also shaft 2 can be made of a transparent material such that the steel balls 7 can be observed through the transparent body of shaft 2.

The length of ball holder 1 is at least the same to that of bearing body 4 or longer.

Figure 7 illustrates the process for assembling saddle 6 from bearing body 4, end caps 5, steel balls 7... and ball holder 1.

The process proceeds as follows:

Step 1. End cap 5 is attached at one end, preferably at a bottom end, of bearing body 4. Then it is fed, with, preferably, the attached end cap facing downward and an open end of bearing body 4 facing upward.

Step 2. Raceway Spacer A is inserted into the open cavity within bearing body 4 by Raceway Spacer Moving Device B. Raceway Spacer A is provided with a plurality of grooves 30... each corresponding to each of grooves 8... of bearing body 4. The diameter of each raceway space 9 formed by complementary grooves 30 and 8 is same or slightly larger than that of steel ball 7.

Step 3. Steel balls 7 are fed into raceway spaces 9... and escape-ball through holes 10... Due to end cap 5 attached at the bottom of bearing body 4, steel balls 7... are easily fed by Ball Feed Device C into raceway spaces 9..., escape-ball through holes 10... and ball-recirculating grooves in end cap 5.

Step 4. Close top open end surface of bearing body 4 by a second end cap 5. It is preferable that ball-recirculating grooves in second end cap 5 are previously filled with steel balls 7... At this stage saddle 6 is formed by bearing body 4 and a pair of end caps 5, 5, Raceway Spacer A, and a plurality of steel balls 7..., however, there is no preload provided in any of steel balls 7... yet.

Step 5. Ball holder 1 is positioned at beneath of bottom end cap 5 and then saddle 6 is slid down onto ball holder 1. Since the material of ball holder 1 is much softer than that of steel balls 7 and of bearing body 4, ball holder 1 is slightly compressed without imparting much preload in steel balls 7... so that it is firmly maintained within saddle 6 by friction.

It is preferable that ball holder 11 is further provided with end plate 15 at its one end as shown in Figure 8 . End plate 15 has a peripheral configuration substantially identical to the overall configuration of end cap 5.

Shaft 2 of the ball holder 2 can be made longer than that of saddle 6 and be provided at both distal ends with detachable end plates 12, 12 as shown in Figure 9. Each of end plates 12, 12 has a shape substantially identical to the size of overall configuration of end cap 5 and is provided with a window 13 through which the distal end of shaft 2 fits with friction. Then the ball holder 1 can be maintained within saddle 6 with certainty since end plates 12, 12 holds saddle 6 therebetween.

One of end plates 12, 12 can be permanently fixed at a distal end of shaft 2.

Further, as shown in Figure 10, a fit plate 14′ can be provided at one end of shaft 2. Or step portion 14" can be provided between end plate 15" and shaft 20" as shown in Figure 11. Fit plate 14′ or step portion 14" abuts within the inner opening of end cap 5 in order to reinforce the frictional gripping. One advantage of the embodiments shown in Figure 10 and 11 is that it is easy to align the shaft with accuracy within the bearing body due to friction plate 14′ or step portion 14" such that it makes it easier to reassemble saddle 6, the steel balls 7... and ball holder 11′ after saddle 6 was accidentally removed from the rail R without using ball holder 11′ and steel balls 7... fell off to the ground.

Next embodiments shown in Figures 12 through 20 are directed to the ball holder capable to provide adjustable raceway spaces.

Figure 12 illustrates adjustable ball holder 21 composed of a pair of independent first and second shaft parts 22 and 23. First shaft part 22 is provided with a concave 24. Concave 24 is provided with a inclined bottom surface 28. On the other hand, second shaft 23 has inclined projection 25 which fits into concave 24. When first and second shaft 22 and 23 are assembled with both end surfaces flushing each other, they rest with a small clearance 26 therebetween and their combined end surfaces form a configuration substantially identical to that of track shaft part T of rail R.

As first and second shaft parts 22 and 23 are slightly dislocated from each other along their axial direction, clearance 26 is eliminated. Adjustable ball holder 21 of this contracted state is first inserted into the cavity of bearing body 4 and steel balls 7... are fed into enlarged raceway spaces 9.... Each of raceway spaces 9... formed by grooves 31... of adjustable ball holder 21 and grooves 8... of bearing body 4 is slightly larger than steel balls 7... so that filling of steel balls 7... is easily accomplished.

After all raceway spaces 9... and escape-ball through holes 10... and ball-recirculating grooves in end cap 5 are filled with steel balls 7..., another end cap 5 is fixed to cover the opening end of bearing body 4. Then first and second shaft parts 22 and 23 are axially slid until both end surfaces flush each other. The relative position of first and second shaft parts 22 and 23 is maintained by friction, or preferably by detachable screw 27. Alternatively, stop cover 28 as shown in Figure 15 can be used instead of screw 27.

Figure 16 shows another embodiment of second shaft 22′ provided with fit plate 14′ which fits into the inner opening of end cap 5.

Figure 17 shows still another embodiment of first and second shaft 22" and 23" in which concave 24′ and projection 25′ are both tapered in their cross-sections.

Figure 18 illustrates still further embodiment in which shaft 33 is somewhat tubular and has a cross-sectional configuration almost identical to that of track shaft part T of rail R except it has a cut opening 35 at its bottom formed by a pair of lips 34, 34. Provided at the four corners of ball holder 33 are grooves 35... substantially identical to those of track shaft part T of rail R.

Figures 19 and 20 show different embodiments of such ball holder which are here made of metal. In Figure 20, ball holder 43′ is provided with windows 46 which enable easy holding of the steel balls 7...

In each of those embodiments, the outer configuration of ball holder 33... is substantially identical to that of track shaft part T, however, becomes smaller when lips 34 and 34 are held to contact each other as shown in Figure 21 such that the diameter of each raceway space 9 formed therein becomes slightly larger than that of steel ball 7. After steel balls 7... are filled in the raceway spaces, lips 34 and 34 are released so that ball holder 33 springs back to its original shape and steel balls 7... are held between bearing body 4 and ball holder 33.

Figure 22 illustrates insertion member 40 to be inserted into clearance 35 between lips 34 and 34. Since the width of projection 41 of stop member 40 is slightly larger than clearance 35 between lips 34 and 34 after the steel balls 7... are filled, ball holder 33 is even more firmly held in saddle 6 when stop insertion 40 is inserted.

Further, insertion member 40 prevents ball holder 33 from being deformed due to the resistance from preloaded steel balls 7... when saddle 6 slides onto rail R and thus also prevents steel balls 7... from falling off due to the possible deformation.

Figure 23 illustrates another insertion member 42 having recess 43 and projection 44. Recess 43 works to hold lips 34 and 34 to contact each other.

Figure 24 illustrates another embodiment of adjustable ball holder 53 having end plate 55 and a pair of separated cantilever projections 52, 52 projecting therefrom.

The outer configuration of end plate 55 is substantially identical to that of end cap 5 or of bearing body 4. Therefore, when ball holder 53 is inserted into saddle 6, with the position of side plate 55 exactly coincides with end cap 5, the positions of separated cantilever projections 52 and 52 are also determined in the exact locations to provide the raceways 9... each slightly smaller than the diameter of steel balls 7...

Then the central clearance 57 between separated cantilever projections 52 and 52 is narrowed by holding lips 54 and 54 to contact each other in order to fill the steel balls 7... into the slightly widened raceways 9.... After completion of filling steel balls 7..., lips 54 and 54 are released so that separated cantilever projections 52 and 52 hold steel balls 7... against the grooves 8... of bearing body 4.

Figure 25 illustrates another embodiment of ball holder 63 provided with fit plate 65 which abuts with the inner opening of end cap 5 with friction. Also, cantilever projections 62, 62 are separated from fit plate 65 with clearance 66 such that cantilever projections 62 and 62 can be easily inclined.

Figure 26 illustrates insertion member 70 having a projection 71 and tapered recess 73. The outer cross-section of insertion member 70 is identical to the inner cross-section of the inner cavity between cantilever projections 52 and 52 or 62 and 62.

First, clearance 57 or 67 is narrowed by moving tapered recess 73 onto lips 54 and 54 or 64 and 64. After steel balls 7... are supplied, insertion member 70 is withdrawn from the lips. Then whole insertion member 70 is inserted into the inner cavity of cantilever projections 52 and 52 or 62 and 62 such that ball holder 53 or 63 hold steel balls 7... more firmly.

Figure 27 illustrates short insertion member 80 with recess 83. The length L of recess 83 is much shorter than the distance between the outer edges of the lips 54 and 54 or 64 and 64 in order to close clearance 57 or 67.

The width W of short insertion member 80 is slightly substantially identical to clearance 57 or 67. Thus when saddle 6 is assembled, short insertion member 80 is inserted into narrowed clearance 57 or 67 by steel balls 7... so as to push the cantilever projections outwardly.

What is claimed is:

1. A retainerless linear motion bearing assembly having a bearing body, a pair of end caps, a rail, and rows of steel balls; characterized in that said bearing body has a substantially C-shaped recess provided with a plurality number of grooves therein and same number of through holes in said bearing body; each of said pair of end caps is fixed at each end surface of said bearing body and provided with same number of ball-recirculating grooves; said rail is provided with same number of grooves positioned adjacent to said plurality number of grooves of said bearing body so as to form raceways such that said raceways, said ball-recirculating grooves and said through holes form same number of independent recirculating loop channels; each of said same number of rows of steel balls is placed within each of said independent recirculating loop channels; and a diameter of each of said balls is slightly larger than a diameter of each of said raceways such that said balls within said raceways are preloaded.

2. A ball holder for a retainerless saddle having a bearing body, a pair of end caps attached to said bearing body, an elongated shaft, and a plurality of contact surfaces; characterized in that said elongated shaft has an axial length at least equal to that of the bearing body; said plurality of contact surfaces is provided at the circumstantial surface of said elongated shaft along the axis thereof; each of said contact surfaces positioned adjacent to each of grooves provided within the bearing body such that each of said contact surfaces of said shaft and each of said grooves of the bearing body form an independent raceway, and the outer configuration of the cross-section of said ball holder is substantially identical to that of the cross-section of a track shaft part of a rail.

3. The ball holder of claim 2, characterized in that each of said contact surfaces has a groove.

4. The ball holder of claim 2, characterized in that each of said contact surfaces has a slit.

5. The ball holder of claim 3, characterized in that a material of the ball holder is an elastic member.

6. The ball holder of claim 4, characterized in that a material of the ball holder is a metal.

7. The ball holder of claim 2, characterized in that the diameter of said raceway is substantially identical to that of a steel ball.

8. The ball holder of claim 2, characterized in that the diameter of said raceway is slightly smaller than that of the steel ball.

9. The ball holder of claim 2, characterized in that said shaft is provided with an end plate at one distal end thereof, and that said end plate has an outer configuration substantially identical to the overall outer configuration of said end cap.

10. The ball holder of claim 2, characterized in that said shaft is provided with a fit plate at one distal end thereof, and that said fit plate has an outer configuration substantially identical to the inner peripheral configuration of an opening of said end cap.

11. The ball retainer of claim 10, characterized in that said fit plate is provided with an end plate.

12. The ball holder of claim 2, characterized in that said shaft is composed of a plurality of shaft parts.

13. The ball holder of claim 12, characterized in that said plurality of shaft parts are a pair of first and second shaft parts, and that said first and second shaft parts are engageable with each other.

14. The ball holder of claim 13, characterized in that said first shaft part is provided with an open recess and said second shaft part is provided with a projection, and that the cross-sectional configurations of said open recess and said second shaft are substantially identical.

15. The ball holder of claim 14, characterized in that said open recess has an inclined bottom surface, and that said projection has an inclined top surface.

16. The ball holder of claim 14, characterized in that each of said open recess and said projection has a tapered cross-section.

17. The ball holder of claim 14, characterized in that said first and second shaft parts are attached with a detachable screw.

18. The ball holder of claim 14, characterized in that said second shaft part has a fit plate.

19. The ball holder of claim 14, characterized in that said first and second shaft part are held by a stop member.

20. The ball holder of claim 2, characterized in that said shaft is a hollow tube having a pair of lips with a slit therebetween.

21. The ball holder of claim 20, characterized in that said shaft is made of a metal.

22. The ball holder of claim 21, characterized in that each of said contact surfaces is provided with a window.

23. The ball holder of claim 20, characterized in that said slit between the pair of lips have an insertion member inserted thereinto.

24. The ball holder of claim 12, characterized in that said plurality of shaft parts are a pair of cantilever projections connected at the root thereof.

25. The ball holder of claim 24, characterized in that each of said cantilever projections is provided with a lip.

26. The ball holder of claim 24, characterized in that a space between said lips accommodate therein an insertion member inserted therein.

27. The ball holder of claim 26, characterized in that said ball holder further has a recess.

28. The ball holder of claim 26, characterized in that said insertion member has a projection at one side and a recess at the other side, and that said insertion member has a cross-section substantially identical to a space between said cantilever projections and said lips.

29. The ball holder of claim 28, characterized in that the width of said recess is tapered.

30. The ball holder of claim 24, characterized in that at least said lips are directly connected to a common plate.

31. The ball holder of claim 30, characterized in that said common plate is an end plate having an outer configuration substantially identical to that of said end cap.

32. The ball holder of claim 30, characterized in that said common plate is a fit plate having an outer configuration substantially identical to the inner configuration of an open cavity of said end plate.

33. The ball holder of claim 30, characterized in that each of said cantilever projections is separated from said common plate.

34. A process for assembling a retainerless saddle for a linear motion bearing having a bearing body, steel balls, a pair of end caps and a ball holder; characterized in that said assembling process attaches one of said end caps at one end surface of said bearing body; provides raceways within said bearing body, the diameter of the raceway being slightly larger than that of the steel ball; feeds said steel balls into said raceways and escape-ball through holes in said bearing body; covers an open end of said bearing body by the other end cap so as to form a saddle; and holds said balls between said saddle and said ball holder.

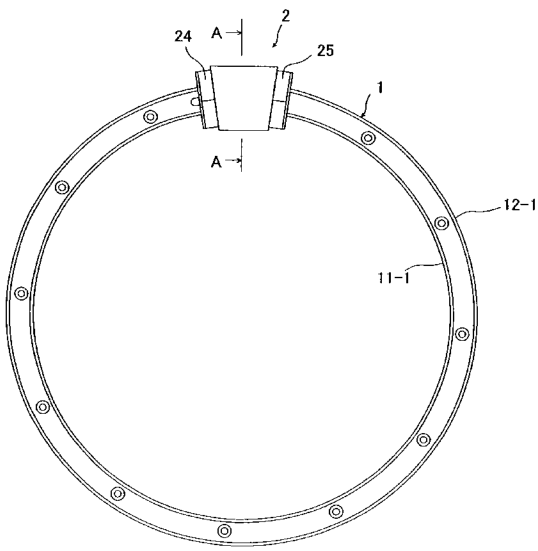
(54) Bezeichnung: **Führungsvorrichtung**

(57) Zusammenfassung: Eine Führungsvorrichtung ist mit einer geteilten Standardendplatte ausgerüstet, wobei die beiden Endplattenhälften mit hoher Genauigkeit zueinander positioniert werden können und an jedem axialen Ende eines bewegbaren Blockkörpers zuverlässig befestigt werden, so daß keine Gefahr des Verschiebens beider zueinander bei Verwendung der Führungsvorrichtung besteht. Auf der Spurschiene der Führungsvorrichtung ist ein relativ zu dieser bewegbarer Block angeordnet. Der Körper des bewegbaren Blocks hat rechtwinklig zur axialen Richtung eine Geometrie, welche die Montage des Blocks an einem Zwischenstück der Spurschiene auf diese ermöglicht. Die Endplatte ist in Breitenrichtung im wesentlichen aus einer linken und einer rechten Hälfte zusammengesetzt. Aus der Verbindungsfläche einer der beiden Endplattenhälften ragt ein positionierzapfen. Die Verbindungsfläche der anderen Endplattenhälfte ist mit einer Positionierbohrung versehen. Beim Zusammenfügen der beiden Endplattenhälften zu einer Einheit gleitet der Positionierzapfen in die Positionierbohrung. Zum Befestigen der auf diese Weise zusammengefügten Endplatte in Richtung der Relativbewegung an einem Ende des bewegbaren Blockkörpers werden durch die an den Endplattenhälften vorhandenen Befestigungsbohrungen Schrauben in diesen gedreht.



Beschreibung

HINTERGRUND DER ERFINDUNG

[0001] Die vorliegende Erfindung betrifft eine Führungsvorrichtung mit einer Spurschiene, einem auf dieser angeordneten und relativ zu dieser bewegbaren Block und mehreren zwischen der Spurschiene und dem bewegbaren Block angeordneten Rollelementen (Kugeln oder Walzen). Genauer ausgedrückt, die vorliegende Erfindung betrifft eine Führungsvorrichtung, bei welcher der bewegbare Block auf eine endlose Spurschiene in Ringform oder eine Spurschiene mit einer zu deren beiden Enden hin ansteigenden Rollbahn für Rollelemente montiert wird.

[0002] Anzumerken ist, daß der Begriff „relativ bewegbar" sich auf die relative Bewegbarkeit des Blocks und der Spurschiene zueinander bezieht und für zwei Fälle gilt, den Fall, bei welchem die Spurschiene fest angeordnet und der Block bewegbar ist, und den Fall, bei welchem der Block fest angeordnet und die Spurschiene bewegbar ist.

[0003] Bei der nachfolgend beschriebenen Führungsvorrichtung ist der Block bewegbar auf der Spurschiene angeordnet und zwischen beiden sind zahlreiche Rollelemente angeordnet.

[0004] Bei einer solchen Führungsvorrichtung kann ein herkömmlicher Block nicht von oben auf die Spurschiene (rittlings auf diese) montiert werden. Aus diesem Grund wird der bewegbare Block von einem Ende der Schiene aus auf diese geschoben.

[0005] Im Falle einer Spurschiene in Form eines endlosen Rings oder im Falle einer Spurschiene mit einer zu deren beiden Enden hin ansteigenden Rollbahn kann der bewegbare Block nicht von einem Ende der Spurschiene auf diese geschoben werden.

[0006] Demzufolge wird auf herkömmliche Weise ein Abschnitt der Spurschiene mit einer bestimmten Länge als separat bewegbares Segment ausgeführt. Zum Montieren des bewegbaren Blocks auf die Spurschiene wird dieses Segment entfernt und der bewegbare Block von einem Ende der jetzt offenen Spurschiene auf diese geschoben. Danach wird das Segment wieder eingesetzt und an der Spurschiene befestigt.

Stand der Technik

[0007] Es besteht aber auch die Möglichkeit, den bewegbaren Block so zu konfigurieren, daß dieser von oben auf die Spurschiene geschoben werden kann, und jede Endplatte in Breitenrichtung (d.h. rechtwinklig zur Bewegungsrichtung) in zwei Hälften zu teilen, wie im japanischen Dokument Sho 58-142017 (KOKAI) offenbart. In diesem Fall werden nach dem Aufsetzen des beweglichen Blocks auf die Spurschiene paarige Endplattenhälften in Bewegungsrichtung an jedem Ende des Blocks befestigt. Durch eine solche Anordnung kann der bewegbare Block auch auf eine endlose ringförmige Spurschiene oder auf eine Spurschiene mit einer zu deren beiden Enden hin ansteigenden Rollbahn montiert werden.

[0008] Im japanischen Dokument Hei 8-21440 (KOKAI) ist eine Führungsvorrichtung offenbart, bei welcher ein entsprechend konfigurierter bewegbarer Block von der Seite auf eine Spurschiene in Form eines endlosen Rings montiert werden kann.

[0009] Gemäß dem zuerst erwähnten herkömmlichen Verfahren ist in Breitenrichtung jede Endplatte in zwei Hälften geteilt, wobei nach dem Aufsetzen des bewegbaren Blocks auf die Spurschiene die aus zwei Hälften zusammengesetzte Endplatte in Bewegungsrichtung am Blockkörper befestigt wird, wie im Dokument Sho 58-142017 (KOKAI) offenbart. Nach diesem Verfahren können die beiden Endplattenhälften nicht oder nur unter Schwierigkeiten mit hoher Genauigkeit zueinander positioniert werden. Selbst wenn es gelingt, beide Hälften der Endplatte genau zueinander zu positionieren, besteht während der Nutzung der Führungsvorrichtung die Wahrscheinlichkeit, daß diese sich verschieben.

[0010] Bei der im japanischen Dokument Hei 8-21440 (KOKAI) offenbarten Führungsvorrichtung müssen der bewegbare Block und die Endplatten so konfiguriert sein, daß der bewegbare Block von der Seite auf die Spurschiene montiert und von dieser demontiert werden kann. Ein herkömmlicher Standardblockkörper und herkömmliche Endplatten können bei einer Führungsvorrichtung gemäß dem Stand der Technik nicht verwendet werden.

Aufgabenstellung

ZUSAMMENFASSUNG DER ERFINDUNG

[0011] Die Aufgabe der vorliegenden Erfindung besteht darin, die bei einer Führungsvorrichtung gemäß dem Stand der Technik auftretenden Probleme zu beseitigen und eine Führungsvorrichtung bereitzustellen, bei welcher die beiden Hälften einer Standardendplatte mit hoher Genauigkeit zueinander positioniert werden können und eine solche aus zwei Hälften zusammengesetzte Endplatte an jedem axialen Ende eines bewegbaren Blockkörpers sicher befestigt werden kann, ohne daß bei Nutzung der Führungsvorrichtung die Gefahr des Verschiebens der beiden Endplattenhälften besteht.

[0012] Diese Aufgabe erfüllt eine Führungsvorrichtung mit einer Spurschiene, in welche eine längs sich erstreckende Rollbahn für Rollelemente eingearbeitet ist, und einem auf der Spurschiene bewegbar zu dieser angeordneten bewegbaren Block. In den Körper dieses bewegbaren Blocks ist eine Lastaufnahmerollbahn eingearbeitet, welche zusammen mit der Rollbahn an der Spurschiene einen Rollkanal für die Lastaufnahmeelemente bildet. Der Blockkörper ist außerdem mit einer Entlastungsbohrung versehen, welche zur Rollbahn an der Spurschiene Verbindung hat. In Bewegungsrichtung des bewegbaren Blocks ist an jedem Ende des Blockkörpers eine Endplatte befestigt. Die Endplatte ist mit einer Richtungsumkehr-Rollbahn versehen, welche zusammen mit dem Rollkanal und der Entlastungsbohrung einen Zirkulationskanal für die Rollelemente bildet. Im Zirkulationskanal sind mehrere Rollelemente untergebracht, welche bei einer Relativbewegung zwischen dem bewegbaren Block und der Spurschiene in diesem zirkulieren.

[0013] Gemäß einem ersten Merkmal der vorliegenden Erfindung hat der bewegbare Blockkörper in einem Abschnitt rechtwinklig zur axialen Richtung eine Geometrie, welche dessen Montage auf die Spurschiene an einem bestimmten Schienenabschnitt ermöglicht. Die Endplatte ist in Breitenrichtung im wesentlichen aus zwei Hälften, d.h. einer rechten und einer linken Hälfte zusammengesetzt. Beide Endplattenhälften können durch Verbindungselemente mit hoher Genauigkeit zueinander positioniert werden. Die über die Verbindungselemente zusammengesetzte Endplatte wird in Bewegungsrichtung des Blocks mit Befestigungselementen an einem Ende des Blockkörpers befestigt.

[0014] Gemäß einem zweiten Merkmal der vorliegenden Erfindung gehören zu den Verbindungselementen entsprechend dem ersten Merkmal ein aus der Verbindungsfläche an einer der beiden Endplattenhälfte ragender Positionierzapfen und eine in der Verbindungsfläche der anderen Endplattenhälfte vorhandene Positionierbohrung. Mit dem Einführen des Positionierzapfens in die Positionierbohrung werden die beiden Hälften zu einer Einheit zusammengefügt. Zu den erwähnten Befestigungselementen gehören Befestigungsbohrungen in den Endplattenhälften und Befestigungsschrauben. Die Befestigungsschrauben werden durch die Befestigungsbohrungen geführt und in Bewegungsrichtung des Blockes in ein Ende des Blockkörpers gedreht.

[0015] Gemäß einem dritten Merkmal der vorliegenden Erfindung gehören zu den Verbindungselementen entsprechend dem ersten Merkmal eine in jede Endplattenhälfte in einem bestimmten Abstand von deren Verbindungsfläche eingebrachte Positionierbohrung und ein U-förmiges Positionierelement, dessen Schenkel in die Positionierbohrungen gedrückt werden. Das Positionierelement wird eingesetzt, nachdem die beiden Endplattenhälften gegeneinander gedrückt wurden und deren Verbindungsflächen sich berühren. Zu den erwähnten Befestigungselementen gehören Befestigungsbohrungen in den Endplattenhälften und Befestigungsschrauben. Die Befestigungsschrauben werden durch die Befestigungsbohrungen geführt und in Bewegungsrichtung des Blockes in ein Ende des Blockkörpers gedreht.

[0016] Gemäß einem vierten Merkmal der vorliegenden Erfindung gehört zu den Befestigungselementen entsprechend dem ersten Merkmal ein U-förmiges Halteelement. Nach dem Gegeneinanderdrücken der beiden Endplattenhälften an den Verbindungsflächen werden die Schenkel des U-förmigen Verbindungselements über die Außenfläche jeder Endplattenhälfte geschoben, um die beiden Hälften zu einer Einheit zusammenzufügen. Zu den erwähnten Befestigungselementen gehören Befestigungsbohrungen in den Endplattenhälften und Befestigungsschrauben. Die Befestigungsschrauben werden durch die Befestigungsbohrungen geführt und in Bewegungsrichtung des Blockes in ein Ende des Blockkörpers gedreht.

[0017] Gemäß einem fünften Merkmal der vorliegenden Erfindung gehören zu den Verbindungselementen entsprechend dem ersten Merkmal ein Vorsprung und eine Vertiefung an der entsprechenden Verbindungsfläche jeder Endplattenhälfte. Der Vorsprung und die Vertiefung an der einen Endplattenhälfte werden mit der Vertiefung und dem Vorsprung an der anderen Endplattenhälfte ineinandergeschoben, um die beiden Endplattenhälften zu einer Einheit zusammenzufügen und deren Auseinanderdriften in Breitenrichtung zu verhindern. Zu den erwähnten Befestigungselementen gehören Befestigungsbohrungen in den Endplattenhälften und Befestigungsschrauben. Die Befestigungsschrauben werden durch die Befestigungsbohrungen geführt und in Bewegungsrichtung des Blockes in ein Ende des Blockkörpers gedreht.

[0018] Gemäß einem sechsten Merkmal der vorliegenden Erfindung gehört zu den Verbindungselementen entsprechend dem ersten Merkmal ein unbearbeiteter zylindrischer Stopfen, welcher in die Aussparung an der Verbindungsfläche einer Endplattenhälfte gedrückt wird und teilweise aus dieser Verbindungsfläche ragt. Die Verbindungsfläche der anderen Endplattenhälfte ist mit einer Aussparung versehen, in welche der aus der Verbindungsfläche der ersten Endplattenhälfte ragende Teil des unbearbeiteten zylindrischen Stopfens paßt. Beim Gegeneinanderdrücken der beiden Endplattenhälften an den Verbindungsflächen gleitet der aus der einen Verbindungsfläche ragende Teil des unbearbeiteten zylindrischen Stopfens in die Aussparung an der anderen Verbindungsfläche, um die beiden Endplattenhälften zu einer Einheit zusammenzufügen. Zu den erwähnten Befestigungselementen gehören Befestigungsbohrungen in den Endplattenhälften und Befestigungsschrauben. Die Befestigungsschrauben werden durch die Befestigungsbohrungen geführt und in Bewegungsrichtung des Blockes in ein Ende des Blockkörpers gedreht.

[0019] Gemäß einem siebenten Merkmal der vorliegenden Erfindung hat die Endplatte entsprechend dem ersten Merkmal rechtwinklig zur axialen Richtung einen annähernd U-förmigen Querschnitt und wird rittlings auf die Spurschiene gedrückt. In diesem Fall sind die beiden Endplattenhälften über einen Steg teilweise miteinander verbunden. Beim Montieren dieser Endplatte werden die beiden Hälften über den Steg auseinander geschwenkt, so daß die von den Schenkeln der Endplatte gebildete Öffnung in Breitenrichtung größer wird und die Endplatte über den Schienenkopf geschoben werden kann. Zu den erwähnten Befestigungselementen gehören Befestigungsbohrungen in den Endplattenhälften und Befestigungsschrauben. Die Befestigungsschrauben werden durch die Befestigungsbohrungen geführt und in Bewegungsrichtung des Blockes in ein Ende des Blockkörpers gedreht.

[0020] Gemäß einem achten Merkmal der vorliegenden Erfindung ist die Spurschiene entsprechend einem der Merkmale eins bis sieben als endloser Ring ausgeführt.

[0021] Gemäß einem neunten Merkmal der vorliegenden Erfindung hat die Spurschiene entsprechend einem der Merkmale eins bis sieben eine zu deren beiden Enden hin ansteigende Rollbahn für Rollelemente.

[0022] Die vorliegende Erfindung ist auch auf eine Führungsvorrichtung übertragbar, in deren Spurschiene eine längs sich erstreckende Rollbahn für Rollelemente eingearbeitet ist. Auf dieser Spurschiene ist ein relativ zu dieser bewegbarer Block angeordnet. In den Blockkörper ist eine Lastaufnahmerollbahn eingearbeitet, welche zusammen mit der Rollbahn an der Spurschiene einen Rollkanal für die Lastaufnahmerollelemente bildet. Der Blockkörper ist außerdem mit einer Entspannungsbohrung versehen, welche zur Lastaufnahmerollbahn Verbindung hat. An jedem Ende des bewegbaren Blockkörpers wird in dessen Bewegungsrichtung eine Endplatte befestigt. Die Endplatte ist mit einem Richtungsumkehrkanal versehen, welcher zusammen mit dem Lastaufnahmerollkanal und der Entspannungsbohrung einen Zirkulationskanal für die Rollelemente bildet. Im Zirkulationskanal sind zahlreiche Rollelemente untergebracht, welche bei einer Relativbewegung zwischen der Spurschiene und dem bewegbaren Block in diesem Kanal zirkulieren.

[0023] Gemäß einem zehnten Merkmal der vorliegenden Erfindung hat der bewegbare Blockkörper rechtwinklig zur axialen Richtung eine Geometrie, welche dessen Montage auf die Spurschiene an einem bestimmten Abschnitt an dieser ermöglicht. Die Endplatte ist aus einem elastischen Material gefertigt und hat rechtwinklig zur axialen Richtung einen nahezu U-förmigen Querschnitt. Wenn die Endplatte von oben über den Schienenkopf gedrückt wird, weitet deren Öffnung sich. Die Endplatte wird in der Endstellung in Bewegungsrichtung mit Befestigungselementen an einem Ende des Blockkörpers befestigt.

[0024] Gemäß dem ersten bis neunten Merkmal der vorliegenden Erfindung ist jede Endplatte in Breitenrichtung aus zwei Hälften zusammengesetzt. Demzufolge muß die Endplatte nicht von einem Ende der Spurschiene aus auf diese gesetzt, sondern kann an einem Zwischenstück von der Seite auf diese geschoben werden. Die beiden Hälften können mit hoher Genauigkeit zueinander positioniert und anschließend zuverlässig am Blockkörper befestigt werden, so daß die Gefahr der Verschiebens beider während der Nutzung der Führungsvorrichtung nicht besteht. Demzufolge kann der bewegbare Körper auch auf eine Spurschiene in Form eines endlosen Rings, auf eine Spurschiene mit einer zu deren beiden Enden hin ansteigenden Rollbahn oder auf eine Spurschiene mit einer Begrenzung am Ende montiert werden, da die Montage an einem Zwischenstück der Spurschiene auf diese erfolgt.

[0025] Gemäß dem zehnten Merkmal der vorliegenden Erfindung ist die Endplatte aus einem elastischen Material gefertigt, so daß Breite der Öffnung an dieser durch elastisches Verformen vergrößert wird. Demzufolge kann eine solche einfach konfigurierte Endplatte problemlos auf die Spurschiene gedrückt werden. Demzufolge kann der bewegbare Körper auch auf eine Spurschiene in Form eines endlosen Rings, auf eine Spurschiene mit einer zu deren beiden Enden hin ansteigenden Rollbahn oder auf eine Spurschiene mit einer Begrenzung am Ende montiert werden, da die Montage an einem Zwischenstück der Spurschiene auf diese erfolgt.

BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSFORMEN

[0044] Nachfolgend werden anhand der beiliegenden Zeichnungen Ausführungsformen der vorliegenden Erfindung beschrieben. Die Fig. 1 bis Fig. 4 zeigen den Aufbau einer Führungsvorrichtung gemäß der vorliegenden Erfindung. Von diesen vier Figuren zeigt Fig. 1 die Draufsicht der Führungsvorrichtung, Fig. 2 die Schnittansicht A-A dieser Führungsvorrichtung, Fig. 3 die Vorderansicht einer herkömmlichen Endplatte und Fig. 4 die Draufsicht eines bewegbaren Blockes. Wie aus diesen Figuren hervor geht, weist die Führungsvorrichtung gemäß der vorliegenden Erfindung eine endlose ringförmige Spurschiene **1** und einen auf dieser bewegbar angeordneten Block **2** auf.

[0045] Rechtwinklig zur axialen Richtung (d.h. zur Bewegungsrichtung des Blocks **2**) hat die Spurschiene **1** einen rechteckigen Querschnitt. Auf der linken und auf der rechten Seite der Spurschiene **1** ist im Mittelabschnitt eine Nut vorhanden. Der über der Nut liegende Abschnitt hat links einen Kamm **11** und rechts einen Kamm **12**.

[0046] Die obere Kante der Kämme **11** und **12** ist als Rollbahn **11-1** bzw. **12-1**, deren untere Kante **11** und **12** als Rollbahn **11-2** bzw. **12-2** für Rollelemente (Kugeln bei diesem Beispiel) ausgeführt.

[0047] Der bewegbare Block **2** hat einen U-förmigen Hauptkörper **21** mit einem linken Schenkel **22** und einem rechten Schenkel **23**, welche sich über die Hauptkörperöffnung gegenüber liegen.

[0048] Die Breite L1 der Öffnung (d.h. der Abstand zwischen der Innenseite des Schenkels **22** und der Innenseite des Schenkels **23**) im Hauptkörper **21** ist größer als die Breite L2 zwischen den Kämmen **11** und **12** der Spurschiene **1** (L1>L2). Dadurch kann der Blockkörper **21** von oben (oder von der Seite) auf die Spurschiene geschoben werden.

[0049] Die Innenseite des Schenkels **22** ist mit Axiallastrollbahnen **22-1** und **22-2**, die Innenseite des Schenkel **23** mit Axiallastrollbahnen **23-1** und **23-2** versehen, welche den entsprechenden Rollbahnen **11-1**, **11-2**, **12-1** und **12-2** an der Spurschiene **1** gegenüber liegen.

[0050] Der Schenkel **22** ist mit Entlastungsbohrungen **22-3** und **22-4**, der Schenkel **23** mit Entlastungsbohrungen **23-3** und **23-4** versehen, welche mit den Axiallastrollbahnen **22-1** und **22-2** bzw. **23-1** und **23-2** in Verbindung stehen.

[0051] Die Rollbahnen **11-1** und **11-2** an der Spurschiene **1** und die Axiallastrollbahnen **22-1** und **22-2** am Blockkörper **21** bilden einen Rollkanal R1 bzw. R2, die Rollbahnen **12-1** und **12-2** an der Spurschiene **1** und die Axiallastrollbahnen **23-1** und **23-2** am Blockkörper **21** einen Rollkanal R3 bzw. R4 für die Lastaufnahmerollelemente.

[0052] An einer der beiden axialen Stirnseiten des Blockkörpers **21** ist eine Endplatte **24**, an der anderen eine Endplatte **25** befestigt. Die beiden Endplatten **24** und **25** sind mit Richtungsumkehrkanälen R5, R6, R7 und R8 versehen, welche die in den Rollkanälen R1, R2, R3 und R4 rollenden Rollelemente (Kugeln) **3** in die entsprechende der vier Entlastungsbohrungen **22-3**, **22-4**, **23-3** und **23-4** gleiten lassen und dabei deren Bewegungsrichtung umkehren.

[0053] Mit anderen Worten, beim Bewegen des Blockes **2** zirkulieren die zahlreichen Rollelemente (Kugeln) **3** in jedem der aus dem entsprechenden Rollkanal R1, R2, R3, R4, der entsprechenden Entlastungsbohrung **22-3**, **22-4**, **23-3**, **23-4** und dem entsprechenden Umkehrkanal R5, R6, R7, R8 gebildeten Zirkulationskanälen.

[0054] Wie bereits erwähnt, ist die Breite L1 der Öffnung im Blockkörper **21** größer als der Abstand zwischen den Kämmen **11** und **12** der Spurschiene **1** (L1>L2), so daß auch bei einer endlosen ringförmigen Spurschiene **1** der Blockkörper **21** von oben (oder von der Seite) auf diese geschoben werden kann.

[0055] Im Gegensatz dazu haben die Endplatten **24** und **25** im allgemeinen die in Fig. 3 dargestellte Konfiguration. Das heißt, die Breite L3 der Öffnung dieser beiden Endplatten **24**, **25** ist kleiner als der Abstand L2 zwischen den beiden Kämmen **11** und **12** der Spurschiene **1** (L2>L3). Demzufolge können auch die Endplatten **24** und **25** nicht von oben (oder von der Seite) auf die Spurschiene **1** geschoben werden.

[0056] Unter diesen Gegebenheiten wurden gemäß der vorliegenden Erfindung die Endplatten **24** und **25** konstruktiv so verbessert, daß diese von oben auf die Spurschiene **1** geschoben werden können.

[0057] Nachfolgend wird nur die Endplatte **24** detailliert beschrieben, da die Endplatte **25** und die Endplatte **24** identisch sind.

[Erste Ausführungsform]

[0058] Die Fig. 5A, Fig. 5B und Fig. 5C zeigen ein Beispiel der Endplatte **24**. Fig. 5A zeigt die Draufsicht dieser Endplatte in Explosivdarstellung, Fig. 5B deren Vorderansicht in Explosivdarstellung und Fig. 5C deren Seitenansicht. In diesen Figuren tragen Elemente, welche den in den Fig. 1 bis Fig. 4 gezeigten identisch sind, die gleichen Bezugszeichen wie diese. Das gilt auch für die anderen Zeichnungen.

[0059] Wie aus den Fig. 5A, Fig. 5B und Fig. 5C hervor geht, hat die Endplatte **24** von vorn auf diese gesehen annähernd eine U-Form und ist aus zwei Hälften **24-1** und **24-2** zusammengesetzt, wobei die Verbindungslinie der Mittellinie der Endplattenöffnung entspricht.

[0060] Die Verbindungsfläche a der Endplattenhälfte **24-1** ist mit einem Positionierzapfen **26**, die Verbindungsfläche b der Endplattenhälfte **24-2** mit einer Positionierbohrung **27** als Aufnahme für den Positionierzapfen **26** versehen. Außerdem ist die Endplattenhälfte **24-1** mit einer Bohrung **28-1**, die Endplattenhälfte **24-2** mit einer Bohrung **28-2** für eine Befestigungsschraube versehen.

[0061] Diese beiden Endplattenhälften **24-1** und **24-2** werden von der Seite auf die Spurschiene **1** geschoben, wobei der Positionierzapfen **26** in die Positionierbohrung **27** gleitet. Das Zusammenfügen der beiden Endplattenhälften zur Endplatte **24** ist beendet, wenn deren Verbindungsflächen a und b einander berühren.

[0062] Dann werden durch die Bohrungen **28-1** und **28-2** Schrauben in den Blockkörper **21** gedreht, um die Endplatte **24** an diesem zu befestigen. Das Bezugszeichen **29** kennzeichnet eine Ölbohrung.

[0063] Wie bereits beschrieben, werden die beiden Endplattenhälften **24-1** und **24-2** von der Seite auf die Spurschiene **1** geschoben, bis deren Verbindungsflächen a und b einander berühren, wobei der Positionierzapfen **26** in die Positionierbohrung **27** gleitet und dadurch beide Endplattenhälften mit hoher Genauigkeit zusammengefügt werden können. Durch die Bohrungen **28-1** und **28-2** werden Schrauben in den Blockkörper **21** gedreht und auf diese Weise die beiden Endplattenhälften exakt und zuverlässig an diesem befestigt und können sich während der Benutzung der Führungsvorrichtung nicht verschieben.

[Zweite Ausführungsform]

[0064] Die Fig. 6A, Fig. 6B, Fig. 6C, Fig. 6D und Fig. 6E zeigen ein weiteres Beispiel der Endplatte **24**. Fig. 6A zeigt die Draufsicht, Fig. 6B die Vorderansicht, Fig. 6C die Seitenansicht dieser Endplatte. Fig. 6D zeigt die Vorderansicht und Fig. 6E die Seitenansicht eines Positionierelements.

[0065] Die Endplatte **24** ist aus einer linken Hälfte und einer rechten Hälfte **24-2** zusammengesetzt. Die obere Fläche der beiden Hälften **24-1** und **24-2** sind in einem bestimmten Abstand von der Verbindungsfläche a bzw. b mit einer Positionierbohrung **30-1** bzw. **30-2** und mit einer Bohrung **28-1** bzw. **28-2** für Befestigungsschrauben versehen.

[0066] Eine Metallplatte oder einer ähnlichen Platte wurde U-förmig zu einem Positionierelement **31** gebogen, dessen Schenkel in die Positionieröffnungen **30-1** und **30-2** gedrückt werden können. Die beiden Endplattenhälften **24-1** und **24-2** werden von der Seite auf die Spurschiene **1** geschoben, bis deren Verbindungsflächen a und b einander berühren. In diesem Zustand werden die Schenkel des Positionierelements **31** wie beschrieben in die Positionieröffnungen **30-1** und **30-2** gedrückt.

[0067] Danach werden durch die Bohrungen **28-1** und **28-2** Befestigungsschrauben in den Blockkörper **21** gedreht, um die auf diese Weise zusammengesetzte Endplatte an einer Seite des Blockkörpers zu befestigen. Diese Konstruktion ermöglicht wie die Konstruktion der Endplatte gemäß der ersten Ausführungsform exaktes Verbinden der beiden Endplattenhälften miteinander und sicheres Befestigen der Endplatte **24** am Blockkörper **21**, so daß während der Benutzung der Führungsvorrichtung keine Verschiebung eintritt.

[0068] Bei dieser Ausführungsform sind die Positionieröffnungen **30-1** und **30-2** an der oberen Fläche der Endplattenhälfte **24-1** bzw. **24-2** vorhanden und in diese werden von oben die Schenkel des Positionierelements **31** gedrückt. Es besteht aber auch die Möglichkeit, die Positionieröffnungen **30-1** und **30-2** in die Stirnseite der Endplattenhälfte **24-1** bzw. **24-2** einzubringen und die Schenkel des Positionierelements **31** von der Seite in diese zu drücken.

[Dritte Ausführungsform]

[0069] Die Fig. 7A, Fig. 7B, Fig. 7C und Fig. 7d zeigen ein weiteres Beispiel der Endplatte **24**. Fig. 7A zeigt die Draufsicht dieser Endplatte **24** und ein Halteelement **32**. Fig. 7B zeigt die Seitenansicht und Fig. 7C die Vorderansicht dieser Endplatte **24**. Fig. 7D zeigt die Vorderansicht des Halteelements **32**.

[0070] Die Endplatte **24** ist aus einer linken Hälfte **24-1** und einer rechten Hälfte **24-2** zusammengesetzt. Die linke Hälfte **24-1** ist mit einer Bohrung **28-1**, die rechte Hälfte mit einer Bohrung **28-2** für Befestigungsschrauben versehen.

[0071] Eine Metallplatte oder ähnliche Platte wurde zu einem U-förmigen Halteelement **32** gebogen. Die beiden Hälften **24-1** und **24-2** werden von der Seite auf die Spurschiene **1** geschoben, bis deren Verbindungsflächen a und b einander berühren. In diesem Zustand wird das U-förmige Halteelement **32** über die Stirnflächen der beiden Hälften geschoben, um eine Einheit zu erhalten.

[0072] Durch die beiden Bohrungen **28-1** und **28-1** werden Schrauben den Blockkörper **21** gedreht, um die Einheit an diesem zu befestigen.

[0073] Auf diese Weise werden die beiden Endplattenhälften **24-1** und **24-2** exakt zueinander positioniert und an einer Seite des Blockkörpers befestigt, so daß diese sich wie bei der ersten und bei der zweiten Ausführungsformen während der Benutzung der Führungsvorrichtung nicht verschieben.

[0074] Bei dieser Ausführungsform wird das Halteelement **32** an der Vorderseite der Endplatte **24** befestigt, kann aber auch an deren Rückseite oder deren Oberseite befestigt werden.

[Vierte Ausführungsform]

[0075] Die Fig. 8A, Fig. 8B und Fig. 8C zeigen ein weiteres Beispiel der Endplatte **24**. Fig. 8A zeigt diese Endplatte in Explosivdarstellung, Fig. 8B deren Vorderansicht und Fig. 8C deren Seitenansicht.

[0076] Die Endplatte **24** ist ebenfalls aus einer linken Hälfte **24-1** und einer rechten Hälfte **24-2** zusammengesetzt. Beide Hälften haben Verbindungsflächen c und d und rechtwinklig zu diesen eine Verbindungsfläche e.

[0077] Die linke Endplattenhälfte **24-1** ist an der Grenzlinie der beiden Verbindungsflächen c und e mit einer Vertiefung f und an der Grenzlinie der beiden Verbindungsflächen d und e mit einem Vorsprung g versehen. Die rechte Endplattenhälfte **24-2** ist an der Grenzlinie der beiden Verbindungsflächen c und e mit einer Vertiefung i und an der Grenzlinie der beiden Verbindungsflächen d und e mit einem Vorsprung h versehen.

[0078] Beim Zusammenfügen der beiden Hälften **24-1** und **24-2** gleitet der Vorsprung g in die Vertiefung i und der Vorsprung h in die Vertiefung f. Auf diese Weise werden die beiden Hälften exakt zueinander positioniert und in Breitenrichtung fixiert.

[0079] Die beiden Endplattenhälften **24-1** und **24-2** werden von der Seite auf die Spurschiene **1** geschoben, bis deren Verbindungsflächen c und deren Verbindungsflächen d einander berühren. Dann werden die beiden Hälften axial gegeneinander gedrückt, wobei der Vorsprung g in die Vertiefung i und der Vorsprung h in die Vertiefung f gleitet. In diesem Zustand werden durch die Bohrungen **28-1** und **28-2** Schrauben in den Blockkörper **21** gedreht, um die Einheit an diesem zu befestigen.

[0080] Auf diese Weise werden die beiden Endplattenhälften exakt zueinander positioniert und an einer Seite des Blockkörpers **21** befestigt, so daß diese sich wie bei der ersten, der zweiten und der dritten Ausführungsform während der Benutzung der Führungsvorrichtung nicht verschieben.

[0081] Die Verbindungsflächen können aber auch anders konfiguriert werden, müssen sich aber berühren und mit einer Vertiefung und einem Vorsprung versehen sein, um ein relatives Verschieben der beiden Endplattenhälften in Breitenrichtung zueinander zu verhindern.

[Fünfte Ausführungsform]

[0082] Die Fig. 9A, Fig. 9B, Fig. 9C und Fig. 9D zeigen ein weiteres Beispiel der Endplatte **24**. Fig. 9A zeigt die Vorderansicht dieser Endplatte, Fig. 9B die Vorderansicht der einen Hälfte dieser Endplatte und Fig. 9C die Vorderansicht der anderen Hälfte dieser Endplatte.

[0083] Wie aus Fig. 9A hervor geht, ist diese Endplatte **24** mit einer Ölbohrung **29** versehen. Die Verbindungslinie der beiden Hälften **24-1** und **24-2** verläuft aber nicht mittig durch diese Ölbohrung **29**, sondern etwas versetzt zu dieser, wie aus den Fig. 9B und Fig. 9C zu erkennen ist.

[0084] Wie aus Fig. 9D hervor geht, wird an der Endplattenhälfte **24-2** ein unbearbeiteter zylindrischer Stopfen **33** in die Ölbohrung **29** gedrückt.

[0085] Die beiden Endplattenhälften **24-1** und **24-2** werden von der Seite auf die Spurschiene **1** geschoben, bis der Verbindungsflächen j einander berühren, wobei die Ölbohrung **29** an der Endplattenhälfte **24-1** über den in die Ölbohrung **29** an der Endplattenhälfte **24-2** eingesetzten unbearbeiteten zylindrischen Stopfen **33** gleitet.

[0086] Durch die Bohrungen **28-1** und **28-2** der auf diese Weise zusammengefügten Einheit werden Schrauben in den Blockkörper **21** gedreht.

[0087] Dadurch können wie bei der ersten bis zur vierten Ausführungsform die beiden Hälften exakt zueinander positioniert und an einer Seite des Blockkörpers **21** befestigt werden, so daß diese sich bei Benutzung der Führungsvorrichtung nicht verschieben.

[Sechste Ausführungsform]

[0088] Bei den Ausführungsformen eins bis fünf der vorliegenden Erfindung wird der Block **2** rittlings auf die Spurschiene **1** montiert. Die Führungsvorrichtung gemäß der vorliegende Erfindung ist aber nicht auf die beschriebene Konfiguration beschränkt, sondern kann auch wie in Fig. 10 dargestellt ausgeführt werden. Bei dieser Ausführungsform hat die Spurschiene **1** einen U-förmigen Querschnitt und in deren Öffnung wird der Block **2** bewegbar eingesetzt.

[0089] Bei der Führungsvorrichtung dieser Konfiguration kann der Blockkörper **21** von oben in die Spurschiene **1** gelegt werden, wobei die Breite der in Bewegungsrichtung an beiden Seiten des Blockkörpers **21** befestigten Endplatten größer ist als die Breite L4 der Spurschienenöffnung.

[0090] Auch in diesem Fall kann durch Verwendung von Endplatten in zwei Hälften **24-1** und **24-2** wie in den Fig. 5A bis Fig. 9D gezeigt der bewegbare Block **2** in die Öffnung der Spurschiene **1** eingesetzt werden. Das heißt, daß die beiden Endplattenhälften **24-1** und **24-2** in der Öffnung der Spurschiene **1** zueinander positioniert, zu einer Einheit zusammengefügt und an einer Seite des Blockkörpers **21** befestigt werden.

[0091] Eine Spurschiene **1** in Form eines endlosen Rings ist an einer Stelle mit einer Aussparung versehen, über welche der Block **2** in die Spurschiene **1** eingesetzt werden kann.

[Siebente Ausführungsform]

[0092] Fig. 11 zeigt die Draufsicht einer weiteren Führungsvorrichtung gemäß der vorliegenden Erfindung. Wie aus Fig. 11 hervor geht, weist diese Führungsvorrichtung eine Spurschiene **1** auf, deren Rollbahnen **11-1** und **11-2** (dargestellt) und Rollbahnen **12-1** und **12-2** (nicht dargestellt an beiden Enden nach oben ansteigen.

[0093] Bei einer Führungsvorrichtung dieser Art kann der bewegbare Block **2** von keiner Seite der Spurschiene **1** aus auf diese geschoben werden.

[0094] Demzufolge muß der Blockkörper **21** entsprechend konfiguriert werden, um diesen wie in Fig. 2 dargestellt von oben auf die Spurschiene **1** montieren zu können. Auch in diesem Fall ermöglicht eine aus zwei Hälften **24-1** und **24-2** zusammengesetzte Endplatte **24** bzw. **25** eine einfache Montage des bewegbaren Blockes **2** auf die Spurschiene **1**.

[Achte Ausführungsform]

[0095] Die Fig. 12A, Fig. 12B und Fig. 12C zeigen noch ein weiteres Beispiel der Endplatte **24**. Fig. 12A zeigt die Draufsicht dieser Endplatte, Fig. 12B deren Vorderansicht und Fig. 12C deren Vorderansicht bei voneinander geschwenkten Hälften.

[0096] Wie aus diesen Figuren hervor geht, sind die beiden Endplattenhälften **24-1** und **24-2** an einem

Steg **34** teilweise miteinander verbunden, so daß die Öffnung dieser Endplatte in Breitenrichtung vergrößert werden kann.

[0097] Die zusammenhängenden Hälften **24-1** und **24-2** der Endplatte **24** werden in Uhrzeigerrichtung bzw. entgegen Uhrzeigerrichtung um den Steg **34** geschwenkt, um die Öffnung der Endplatte **24** zu vergrößern. Dieser Zustand ist in Fig. 12C dargestellt. In diesem Zustand wird die Endplatte **24** über die Spurschiene **1** gestülpt. Danach werden die beiden Hälften **24-1** und **24-2** wieder zurückgeschwenkt.

[0098] Danach werden durch die Bohrungen **28-1** und **28-2** Schrauben in eine Seite des Blockkörper **21** eingeführt, um die Endplatte **24** an diesem zu befestigen.

[0099] Auf diese Weise werden die beiden Endplattenhälften **24-1** und **24-2** exakt zueinander positioniert und am Blockkörper **21** befestigt und können sich wie bei den Ausführungsformen eins bis sechs bei Nutzung der Führungsvorrichtung nicht verschieben.

[Neunte Ausführungsform]

[0100] Die Fig. 13A und Fig. 13B zeigen eine weitere Ausführungsform der Führungsvorrichtung gemäß der vorliegenden Erfindung. Fig. 13A zeigt die Draufsicht, Fig. 13B die Seitenansicht dieser Führungsvorrichtung. Diese Führungsvorrichtung wird in einem Drehtischsystem verwendet.

[0101] Die Führungsvorrichtung dieser Ausführungsform unterscheidet sich von der in Fig. 1 dargestellten darin, daß auf einer ringförmigen Spurschiene **1** mehrere Blöcke, in diesem Fall die Blöcke **2-1**, **2-2** und **2-3** bewegbar montiert sind.

[0102] Jeder dieser drei bewegbaren Blöcke hat einen Blockkörper **21** mit der in Fig. 2 dargestellten Konfiguration. An beiden Axialenden des Blockkörpers **21** werden Endplatten **24** und **25** mit einer der in den Fig. 5A bis Fig. 9D und Fig. 12A bis Fig. 12C Konfiguration befestigt.

[0103] Durch Befestigen eines Tisches **35** auf den drei bewegbaren Blöcken **2-1**, **2-2** und **2-3** kann das in Fig. 13B dargestellte Drehtischsystem erzeugt werden.

[0104] Dieses Drehtischsystem kann nahe dem Belastungspunkt eine Last und demzufolge ein Drehmoment zuverlässig aufnehmen.

[Zehnte Ausführungsform]

[0105] Die Fig. 14A, Fig. 14B und Fig. 15 zeigen noch ein weiteres Beispiel der Führungsvorrichtung gemäß der vorliegenden Erfindung. Fig. 14A zeigt die Draufsicht dieser Führungsvorrichtung, Fig. 14B deren Schnittansicht B-B und Fig. 15 den in Fig. 14B durch das Bezugszeichen C gekennzeichneten Abschnitt vergrößert dargestellt.

[0106] Die Führungsvorrichtung dieser Ausführungsform hat eine endlose Spurschiene **4** in Ringform und mehrere Blöcke **5** (**6**), welche auf deren Oberseite und Unterseite bewegbar montiert sind.

[0107] Die Spurschiene **4** hat rechtwinklig zur axialen Richtung (Bewegungsrichtung der Blöcke) einen annähernd rechteckigen Querschnitt und ist im Mittelabschnitt auf der linken und auf der rechten Seite ausgespart, so daß links oben und unten ein Kamm **41** und recht oben und unten ein Kamm **42** entstanden sind. Auf der linken Seite ist in den oberen linken Kamm **41** der Spurschiene **4** (periphere Innenseite) eine Rollbahn **41-1**, in den unteren Kamm **41** eine Rollbahn **41-2** und auf der rechten Seite (periphere Außenseite) der Spurschiene **4** in den oberen Kamm **42** eine Rollbahn **42-1**, in den unteren Kamm **42** eine und Rollbahn **42-2** für Rollelemente (bei diesem Beispiel Kugeln) eingearbeitet.

[0108] Der bewegbare Block **5** hat einen U-förmigen Hauptkörper **51**, dessen Schenkel **52** und **53** sich gegenüber liegen und eine Öffnung bilden.

[0109] Der bewegbare Block **6** hat einen U-förmigen Hauptkörper **61**, dessen Schenkel **62** und **63** sich gegenüber liegen und eine Öffnung bilden.

[0110] Die Öffnung im Hauptkörper **51** und die im Hauptkörper **61** sind breiter als der Abstand zwischen den Kämmen **41** und **42** an der Spurschiene **4**. Das heißt, daß die Hauptkörper **51** und **61** von oben bzw. unten auf die Spurschiene **4** geschoben werden können.

[0111] Der Rollbahn **41-1** an der Spurschiene **4** gegenüber ist in die Innenfläche des Schenkels **52** eine Rollbahn **52-1**, der Rollbahn **42-1** an der Spurschiene **4** gegenüber in den Schenkel **53** eine Rollbahn **53-1** eingearbeitet.

[0112] Auf gleiche Weise ist der Rollbahn **42-1** an der Spurschiene **4** gegenüber in die Innenfläche des Schenkels **62** eine Rollbahn **62-1**, der Rollbahn **42-2** an der Spurschiene **4** gegenüber in die Innenfläche des Schenkels eine Rollbahn **63-1** eingearbeitet.

[0113] Die beiden Schenkel **52** und **53** des Blockkörpers **51** sind mit i einer Entlastungsbohrung **52-2** bzw. **53-2**, die beiden Schenkel **62** und **63** des Blockkörpers **61** mit einer Entlastungsbohrung **62-2** bzw. **63-2** als Verbindungsbohrung zur jeweiligen Rollenbahn **52-1**, **53-1**, **62-1** bzw. **63-1** versehen.

[0114] In Axialrichtung (Bewegungsrichtung der Blöcke) wird an der Vorderseite und der Rückseite der beiden Blockkörper **51** und **61** eine Endplatte **24'** bzw. **25'** mit einer der in den Fig. 5A bis Fig. 9D und Fig. 12A bis Fig. 12C dargestellten Konfigurationen befestigt.

[Elfte Ausführungsform]

[0115] Die in Fig. 16 gezeigte Endplatte **24'** könnte als Endplatte **24'** bzw. **25'** normalerweise nicht von oben auf die Spurschiene **4** der in den Fig. 14A bis Fig. 15 dargestellte Führungsvorrichtung geschoben werden, da der Abstand L6 zwischen den beiden schöpflöffelförmigen Vorsprüngen **24'-1** und **24'-2** an der entsprechenden Innenfläche der Öffnung in dieser kleiner ist als die Breite L5 (Fig. 15) des oberen Kopfes der Spurschiene **4** (L6<L5).

[0116] Um die Montage dieser Endplatte **24'** von oben zu ermöglichen, wird diese aus einem elastischen Material, zum Beispiel aus Kunstharz gefertigt.

[0117] Die Endplatte **24'** wird von oben auf die Spurschiene **4** gesetzt, dann in Pfeilrichtung F (Fig. 17) nach unten gedrückt und über die vom oberen Schienenkopf berührten Vorsprünge **24'-1** und **24'-2** wie in Fig. 17 durch die Strich-Punkt-Linie E angedeutet elastisch verformt, bis die durch die durchgehende Linie gekennzeichnete Endstellung erreicht ist und deren Vorsprünge **24'-1** und **24'-2** sich in Höhe der Rollbahnen an der Spurschiene **4** befinden.

[0118] Genauer ausgedrückt, beim Herunterdrücken der Endplatte **24'** wird diese elastisch verformt und dadurch der ursprüngliche Abstand zwischen den Vorsprüngen **24'-1** und **24'-2** ausreichend vergrößert (auf L5), damit diese über den Schienenkopf und in die an der Spurschiene **4** vorhandenen Rollbahnen **41-1** und **42-1** gleiten können. Mit dem Erreichen der durch die durchgehende Linie gekennzeichneten Endstellung ist die Montage der Endplatte **24'** auf die Spurschiene **4** abgeschlossen.

[0119] Wie bereits erwähnt, ist die Endplatte **24'** aus einem elastischen Material gefertigt und kann innerhalb des zulässigen Elastizitätsbereichs so verformt werden, daß der Öffnungsabschnitt mit der kleinsten Breite über den Schienenkopf gleiten kann.

[0120] Auf diese Weise können auch einstückig gefertigte Endplatten **24'** mit der in Fig. 16 gezeigten Konfiguration über den oberen und den unteren Kopf auf die Spurschiene **4** geschoben werden, wie aus Fig. 17 hervor geht.

[0121] Anzumerken ist, daß Fig. 17 die Schnittansicht entlang der in Fig. 14A angedeuteten Linie D-D vergrößert zeigt. Da die Endplatte **25'** ebenfalls aus einem elastischen Material gefertigt ist, kann diese auf die gleiche Weise wie die Endplatte **24'** über den oberen und den unteren Schienenkopf der Spurschiene **4** geschoben werden, so daß auf eine Darstellung der Montage dieser Endplatte verzichtet wird.

[0122] Fig. 18 zeigt ein Beispiel der Verwendung der in den Fig. 14A bis Fig. 15 dargestellten Führungsvorrichtung. In diesem Fall handelt es sich um eine Führungsvorrichtung **70**, welche zwischen einer Grundplatte **81** und einer Grundplatte **82** mit einem darauf montierten Roboter **80** angeordnet ist. Auf der Spurschiene **4** dieser Führungsvorrichtung **70** sind mehrere obere Blöcke **5** und mehrere untere Blöcke **6** bewegbar angeordnet.

[0123] Diese Anordnung ermöglicht das Drehen der Spurschiene **4** und der Grundplatte **82** unabhängig voneinander. Wenn an der Spurschiene **4** zum Beispiel ein Werkzeugtisch **83** befestigt wird, können Werkzeuge oder Bauteile ausgewechselt werden, ohne daß der Arm des Roboters **80** geschwenkt werden muß.

[0124] Durch Drehen des Roboters **80** und des Werkzeugtischs **83** zueinander kann die Werkzeugwechselzeit verkürzt werden.

[0125] Die vorliegende Erfindung ist jedoch nicht auf die beschriebenen Ausführungsformen beschränkt, sondern kann vielfältig modifiziert werden. Bei den beschriebenen Ausführungsformen dienen Kugeln als Rollelemente **3**, doch anstatt Kugeln können auch Rollen verwendet werden.

[0126] Bei einer Führungsvorrichtung wird als Standardendplatte eine aus zwei Hälften zusammengesetzte Endplatte verwendet, wobei die beiden Hälften mit hoher Genauigkeit zueinander positioniert und an beiden axialen Enden eines bewegbaren Blocks befestigt werden können, ohne daß bei Nutzung der Vorrichtung die Gefahr des Verschiebens beider zueinander besteht. Der auf der Spurschiene der Vorrichtung angeordnete und bezüglich dieser bewegbare Block hat rechtwinklig zur axialen Richtung einen entsprechenden Querschnitt und kann an einem Zwischenstück der Spurschiene auf diese montiert werden. Die Endplatte ist im wesentlichen aus einer linken und einer rechten Hälfte zusammengesetzt, wobei die eine Hälfte mit einer Befestigungsbohrung und an der Verbindungsfläche mit einem Positionierzapfen, die andere Hälfte mit einer Befestigungsbohrung und an der Verbindungsfläche mit einer Positionierbohrung zur Aufnahme des Positionierzapfens versehen ist. Durch die Befestigungsbohrungen der über den Zapfen und die Bohrung zusammengefügten Endplatteneinheit werden Schrauben in eine der in Bewegungsrichtung liegenden Seiten des bewegbaren Blockes gedreht, um die Endplatteneinheit an diesem zu befestigen.

Patentansprüche

1. Führungsvorrichtung, welche aufweist:
eine Spurschiene (**1**) mit einer in Längsrichtung sich erstreckenden Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) für Rollelemente,
einen auf der Spurschiene (**1**) bewegbar zu dieser angeordneten Block (**2**), wobei
der Blockkörper (**21**) mit einer Lastaufnahmerollbahn (**22-1**, **22-2**, **23-1**, **23-2**), welche zusammen mit der Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) an der Spurschiene (**1**) einen Rollkanal (R1, R2, R3, R4) für die Rollelemente bildet, und außerdem mit einer Entlastungsbohrung (**22-3**, **22-4**, **23-3**, **23-4**), welche mit der Lastaufnahmerollbahn (**22-1**, **22-1**, **23-1**, **23-2**) in Verbindung steht, versehen ist,
eine Endplatte (**24**, **25**) an jeder der beiden Stirnseiten des bewegbaren Blocks (**2**), welche mit einem die Entlastungsbohrung (**22-3**, **22-4**, **23-3**, **23-4**) und den Rollkanal (R1, R2, R3, R4) miteinander verbindenden und zusammen mit diesen einen Zirkulationskanal für die Rollelemente bildenden Richtungsumkehrkanal (R5, R6, R7, R8) versehen ist, und
mehrere im Zirkulationskanal angeordnete Rollelemente (**3**), welche bei der Relativbewegung zwischen der Spurschiene (**1**) und dem bewegbaren Block (**2**) im Zirkulationskanal zirkulieren, wobei
der bewegbare Block (**2**) rechtwinklig zur axialen Richtung einen entsprechenden Querschnitt hat und an einem Zwischenstück der Spurschiene (**1**) auf diese montiert ist,
die Endplatte (**24**, **25**) in Breitenrichtung im wesentlichen aus einer linken Hälfte (**24-1**) und einer rechten Hälfte (**24-2**) zusammengesetzt ist,
die paarigen Hälften der Endplatte durch Verbindungselemente (**26**, **27**, **31**, **32**, **33**) exakt zueinander positioniert sind und die zusammengefügte Endplatte (**24**, **25**) in Bewegungsrichtung des Blocks (**2**) mit Befestigungselementen sicher an einem Ende des Blockkörpers (**21**) befestigt ist.

2. Führungsvorrichtung gemäß Anspruch 1, wobei
der Verbindungsmechanismus
einen aus der Verbindungsfläche an einer der beiden Endplattenhälften ragenden Positionierzapfen (**26**) und
eine an der Verbindungsfläche der anderen Endplattenhälfte vorhandene, zum Positionierzapfen passende Positionierbohrung (**27**) aufweist und
bei zusammengefügter Endplatte (**24**, **25**) der Positionierzapfen (**26**) in die Positionierbohrung (**27**) ragt, wobei
der Befestigungsmechanismus
Befestigungsbohrungen (**28-1**, **28-2**) an den beiden Endplattenhälften (**24-1**, **24-2**) und
Befestigungsschrauben aufweist und
wobei von den durch die Befestigungsbohrungen in Richtung der Relativbewegung in ein Ende des Blockkörpers (**21**) gedrehten Befestigungsschrauben die zusammengefügte Endplatte (**24**, **25**) an diesem gehalten wird.

3. Führungsvorrichtung gemäß Anspruch 1, wobei
der Verbindungsmechanismus
Positionierbohrungen (**30-1**, **30-2**), welche in einem bestimmten Abstand von der Verbindungsfläche an jeder der beiden Endplattenhälften (**24-1**, **24-2**) vorhanden sind, und
ein U-förmig gebogenes Positionierelement (**31**), dessen Schenkel in die Positionierbohrungen passen, aufweist,
bei zusammengefügter Endplatte (**24**, **25**) die Endplattenhälften sich an den Verbindungsflächen berühren und die Schenkel des Positionierelements (**31**) in die Positionierbohrungen (**30-1**, **30-2**) ragen, wobei
der Befestigungsmechanismus
Befestigungsbohrungen (**28-1**, **28-2**) an den beiden Endplattenhälften und
Befestigungsschrauben aufweist und
wobei von den durch die Befestigungsbohrungen (**28-1**, **28-2**) in Richtung der Relativbewegung in ein Ende des Blockkörpers (**21**) gedrehten Befestigungsschrauben die zusammengefügte Endplatte (**24**, **25**) an diesem gehalten wird.

4. Führungsvorrichtung gemäß Anspruch 1, wobei
der Verbindungsmechanismus
ein U-förmig gebogenes Halteelement (**32**) aufweist,
bei zusammengefügter Endplatte (**24**, **25**) die beiden Endplattenhälften sich an den Verbindungsflächen berühren und von den Schenkeln des Halteelements (**32**) in diesem Zustand gehalten werden, wobei
der Befestigungsmechanismus
Befestigungsbohrungen (**28-1**, **28-2**) an den beiden Endplattenhälften und
Befestigungsschrauben aufweist und
wobei von den durch die Befestigungsbohrungen (**28-1**, **28-2**) in Richtung der Relativbewegung in ein Ende des Blockkörpers (**21**) gedrehten Befestigungsschrauben die zusammengefügte Endplatte (**24**, **25**) an diesem gehalten wird.

5. Führungsvorrichtung gemäß Anspruch 1, wobei
der Verbindungsmechanismus
einen Vorsprung (g, h) und eine Vertiefung (f, i) an jeder Verbindungsfläche der beiden Endplattenhälften aufweist, welche ineinander passen und relatives Verschieben der beiden Endplattenhälften in Breitenrichtung verhindern,
wobei bei zusammengefügter Endplatte (**24**, **25**) die Endplattenhälften sich an den Verbindungsflächen berühren und die Vorsprünge (g, h) in die entsprechenden Vertiefungen (f, i) ragen, wobei
der Befestigungsmechanismus
Befestigungsbohrungen (**28-1**, **28-2**) an den beiden

Endplattenhälften und
Befestigungsschrauben aufweist und
wobei von den durch die Befestigungsbohrungen (**28-1**, **28-2**) in Richtung der Relativbewegung in ein Ende des Blockkörpers (**21**) gedrehten Befestigungsschrauben die zusammengefügte Endplatte (**24**, **25**) an diesem gehalten wird.

6. Führungsvorrichtung gemäß Anspruch 1, wobei
der Verbindungsmechanismus
einen unbearbeiteten zylindrischen Stopfen (**33**), welcher in einer Aussparung (**29**) in der Verbindungsfläche einer der beiden Endplatten positioniert ist und teilweise aus der Verbindungsfläche ragt, und
eine Aussparung (**29**) in der Verbindungsfläche der anderen Endplattenhälfte aufweist,
bei zusammengesetzter Endplatte (**24**, **25**) der an der Verbindungsfläche der einen Endplattenhälfte vorstehende Teil des unbearbeiteten zylindrischen Stopfens (**33**) in die Aussparung (**29**) an der Verbindungsfläche der anderen Endplattenhälfte ragt, wobei
der Befestigungsmechanismus
Befestigungsbohrungen (**28-1**, **28-2**) an den beiden Endplattenhälften und
Befestigungsschrauben aufweist und
wobei von den durch die Befestigungsbohrungen (**28-1**, **28-2**) in Richtung der Relativbewegung in ein Ende des Blockkörpers (**21**) gedrehten Befestigungsschrauben die zusammengefügte Endplatte (**24**, **25**) an diesem gehalten wird.

7. Führungsvorrichtung gemäß Anspruch 1, wobei
die Endplatte (**24**, **25**) rechtwinklig zur axialen Richtung einen nahezu U-förmigen Querschnitt hat und rittlings auf der Spurschiene (**1**) sitzt, wobei
der Verbindungsmechanismus
einen Steg (**34**) aufweist, über welchen die beiden Endplattenhälften teilweise miteinander verbunden sind und beim Montieren auf die Spurschiene (**1**) auseinander gedrückt werden, um die Öffnung in dieser zu verbreitern, wobei
der Befestigungsmechanismus
Befestigungsbohrungen (**28-1**, **28-2**) an den beiden Endplattenhälften und
Befestigungsschrauben aufweist und
wobei von den durch die Befestigungsbohrungen (**28-1**, **28-2**) in Richtung der Relativbewegung in ein Ende des Blockkörpers (**21**) gedrehten Befestigungsschrauben die zusammengefügte Endplatte (**24**, **25**) an diesem gehalten wird.

8. Führungsvorrichtung gemäß Anspruch 1, wobei die Spurschiene (**1**) als endloser Ring ausgeführt ist.

9. Führungsvorrichtung gemäß Anspruch 2, wobei die Spurschiene (**1**) als endloser Ring ausgeführt ist.

10. Führungsvorrichtung gemäß Anspruch 3, wobei die Spurschiene (**1**) als endloser Ring ausgeführt ist.

11. Führungsvorrichtung gemäß Anspruch 4, wobei die Spurschiene (**1**) als endloser Ring ausgeführt ist.

12. Führungsvorrichtung gemäß Anspruch 5, wobei die Spurschiene (**1**) als endloser Ring ausgeführt ist.

13. Führungsvorrichtung gemäß Anspruch 6, wobei die Spurschiene (**1**) als endloser Ring ausgeführt ist.

14. Führungsvorrichtung gemäß Anspruch 7, wobei die Spurschiene (**1**) als endloser Ring ausgeführt ist.

15. Führungsvorrichtung gemäß Anspruch 1, wobei die Spurschiene (**1**) eine zu deren beiden Enden hin ansteigende Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) hat.

16. Führungsvorrichtung gemäß Anspruch 2, wobei die Spurschiene (**1**) eine zu deren beiden Enden hin ansteigende Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) hat.

17. Führungsvorrichtung gemäß Anspruch 3, wobei die Spurschiene (**1**) eine zu deren beiden Enden hin ansteigende Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) hat.

18. Führungsvorrichtung gemäß Anspruch 4, wobei die Spurschiene (**1**) eine zu deren beiden Enden hin ansteigende Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) hat.

19. Führungsvorrichtung gemäß Anspruch 5, wobei die Spurschiene (**1**) eine zu deren beiden Enden hin ansteigende Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) hat.

20. Führungsvorrichtung gemäß Anspruch 6, wobei die Spurschiene (**1**) eine zu deren beiden Enden hin ansteigende Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) hat.

21. Führungsvorrichtung gemäß Anspruch 7, wobei die Spurschiene (**1**) eine zu deren beiden Enden hin ansteigende Rollbahn (**11-1**, **11-2**, **12-1**, **12-2**) hat.

22. Führungsvorrichtung, welche aufweist:
eine Spurschiene (**4**) mit einer längs sich erstreckenden Rollbahn (**41-1**, **41-2**, **42-1**, **42-2**),
einen auf der Spurschiene (**4**) angeordneten und relativ zu dieser bewegbaren Block (**5**, **6**),
wobei in den Blockkörper (**51**, **61**) eine Lastaufnahmerollbahn (**52-1**, **53-1**, **62-1**, **63-1**) eingearbeitet ist, welche zusammen mit der Rollbahn (**41-1**, **41-2**, **42-1**, **42-2**) an der Spurschiene (**4**) einen Lastaufnahmekanal (R1, R2, R3, R4) bildet, und der Blockkörper (**51**, **61**) außerdem mit einer Entspannungsbohrung (**52-2**, **53-2**, **62-2**, **63-2**) versehen ist, welche zur

Lastaufnahmerollbahn (**52-1**, **53-1**, **62-1**, **63-1**) Verbindung hat,
eine Endplatte (**24**, **25**) an jeder der beiden Stirnseiten des bewegbaren Blockkörpers (**51**, **61**), welche mit einem Richtungsumkehrkanal (R5, R6, R7, R8) versehen ist, der zusammen mit der Lastaufnahmerollbahn (**52-1**, **53-1**, **62-1**, **63-1**) und der Entspannungsbohrung (**52-2**, **53-2**, **62-2**, **63-2**) einen Zirkulationskanal bildet, und
zahlreiche Rollelemente (**3**), welche im Zirkulationskanal untergebracht sind und bei einer Relativbewegung zwischen dem bewegbaren Block (**5**, **6**) und der Spurschiene (**4**) in diesem zirkulieren,
wobei der Blockkörper (**51**, **61**) rechtwinklig zur axialen Richtung eine Geometrie hat, welche die Montage des Blocks (**5**, **6**) an einem Zwischenstück der Spurschiene (**4**) auf diese ermöglicht,
wobei die Endplatte (**24**, **25**) rechtwinklig zur axialen Richtung annähernd U-Form hat, aus einem elastischen Material gefertigt ist und beim Aufsetzen auf die Spurschiene (**4**) so verformt wird, daß die Breite der Öffnung an dieser sich vergrößert, und
wobei die auf die Spurschiene (**4**) gesetzte Endplatte (**24**, **25**) von den durch die Befestigungsbohrungen (**28-1**, **28-2**) in Richtung der Relativbewegung in ein Ende des bewegbaren Blockkörpers (**51**, **61**) gedrehten Befestigungsschrauben an diesem gehalten wird.

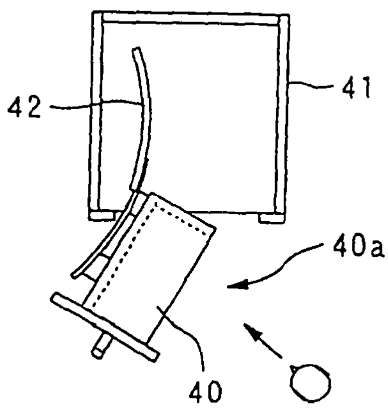
Die folgenden Angaben sind den vom Anmelder eingereichten Unterlagen entnommen

(54) Bezeichnung: **Gleitschieneneinheit**

(57) Zusammenfassung: Gleitschieneneinheit zum Führen eines Gegenstandes (40), der aus einem Körper (41) herauszuziehen ist, in welchem der Gegenstand (40) gleitend aufgenommen ist, aufweisend eine körperseitige Schiene, die für den Körper (41) vorgesehen ist, und eine gegenstandseitige Schiene, die für den Gegenstand (40) vorgesehen ist, um relativ zu der körperseitigen Schiene gleitend ausgezogen zu werden, wobei die körperseitige Schiene und die gegenstandseitige Schiene jeweils einen Abschnitt aufweisen, der in Kreisbogenform derart gebogen ist, dass der Gegenstand (40) entlang einer kreisbogenförmigen Ortskurve ausgezogen wird.



Beschreibung

[0001] Die Erfindung betrifft eine Gleitschieneneinheit zum sanften Führen einer Zieh- oder Schiebebewegung eines Gegenstandes, wie einer Schublade, die aus einem Körper, wie einem Möbelstück, einem Schreibtisch oder dergleichen, herauszuziehen ist.

Stand der Technik

[0002] Eine Gleitschieneneinheit ist zum Beispiel an einer Schublade eines Möbelstücks, eines Schreibtisches oder dergleichen angebracht ist, um zu ermöglichen, dass die Schublade leicht und sanft geöffnet oder geschlossen werden kann. Eine derartige Gleitschieneneinheit ist zum Beispiel in dem japanischen Patent mit der Veröffentlichungsnummer (KOKAI) SHO 51-048046 offenbart, das der DE 2540656, GB 1512069 und US 3966273 entspricht.

[0003] Die Gleitschieneneinheit ist insgesamt aus einer Außenschiene und einer Innenschiene zusammengesetzt, die an der Außenschiene angepasst ist. Eine Anzahl von Kugeln sind zwischen der Außenschiene und der Innenschiene angeordnet. Im Allgemeinen ist die Außenschiene an einem Körper beispielsweise eines Möbelstücks angebracht, und die Innenschiene ist an der Schublade angebracht. Bei dieser Struktur rollen bei Ausübung einer äußeren Kraft auf die Innenschiene die Kugeln zwischen der Innenschiene und der Außenschiene, wodurch die Innenschiene in Bezug auf die Außenschiene gleitet. Ferner ist es zum Erreichen eines großen Hubes der Innenschiene notwendig, die Innenschiene derart zu gestalten, dass deren Länge so groß wie die Länge der Außenschiene ist.

[0004] Im Allgemeinen haben bei der oben genannten herkömmlichen Gleitschienenstruktur sowohl die Außenschiene als auch die Innenschiene eine geradlinige Form, und die Schublade wird daher geradlinig herausgezogen. Bei einer derartigen Struktur kann beim geradlinigen Herausziehen der Schublade der Fall eintreten, dass die Schublade mit einem Hindernis kollidiert oder die Schublade nicht leicht herausgezogen werden kann, was unangenehm ist.

Aufgabenstellung

[0005] Mit der Erfindung wird eine Gleitschieneneinheit geschaffen, bei der die Ortskurve einer Schublade von einer geradlinigen Ortskurve abweicht.

[0006] Dies wird gemäß der Erfindung erreicht durch eine Gleitschieneneinheit zum Führen eines Gegenstandes, der aus einem Körper herauszuziehen ist, in welchem der Gegenstand gleitend aufgenommen ist, aufweisend eine körperseitige Schiene, die für den Körper vorgesehen ist, und eine gegenstandseitige Schiene, die für den Gegenstand vorgesehen ist, um relativ zu der körperseitigen Schiene gleitend ausgezogen zu werden, wobei die körperseitige Schiene und die gegenstandseitige Schiene jeweils einen Abschnitt aufweisen, der in Kreisbogenform derart gebogen ist, dass der Gegenstand entlang einer kreisbogenförmigen Ortskurve ausgezogen wird.

[0007] Gemäß der Erfindung kann der herauszuziehende Gegenstand entlang einer kreisbogenförmigen Ortskurve zum Beispiel in einer vertikalen Ebene oder in einer horizontalen Ebene auf der Basis eines Verfahrens, mittels welchem eine Gleitschiene an einem Körper montiert wird, ausgezogen werden.

[0008] Bei einer bevorzugten Ausführungsform der Erfindung weist die Gleitschieneneinheit eine Außenschiene, die eine der körperseitigen Schiene und der gegenstandseitigen Schiene für den herauszuziehenden Gegenstand bildet, wobei die Außenschiene aus einem Bodenwandabschnitt, der sich in dessen Längsrichtung in Kreisbogenform erstreckt, und einem Paar Seitenwandabschnitten zusammengesetzt ist, die in einer gebogenen Form quer zur Längsrichtung an beiden Längsseiten des Bodenwandabschnitts ausgebildet sind und sich in deren Längsrichtung in Kreisbogenform erstrecken, um dadurch einen Wälzkörperrollabschnitt zu bilden, eine Innenschiene, die eine andere der körperseitigen Schiene und der gegenstandseitigen Schiene bildet, um an die Außenschiene angepasst zu werden, wobei die Innenschiene aus einem Bodenwandabschnitt, der sich parallel zu dem Bodenwandabschnitt der Außenschiene erstreckt, und einem Paar Seitenwandabschnitten zusammengesetzt ist, die in einer gebogenen Form quer zur Längsrichtung an beiden Längsseiten des Bodenwandabschnitts ausgebildet sind und sich in deren Längsrichtung in Kreisbogenform erstrecken, um dadurch einen Wälzkörperrollabschnitt zu bilden, und eine Anzahl von Wälzkörpern auf, die zwischen dem Wälzkörperrollabschnitt der Außenschiene und dem Wälzkörperrollabschnitt der Innenschiene angeordnet sind.

[0009] Die Außenschiene kann in einer virtuellen Ebene des Bodenwandabschnitts der Außenschiene in der Kreisbogenform gebogen sein, und die Innenschiene ist in einer virtuellen Ebene des Bodenwandabschnitts der Innenschiene in der Kreisbogenform gebogen.

[0010] Die Außenschiene kann in einer virtuellen Ebene senkrecht zu dem Bodenwandabschnitt der Außenschiene in der Kreisbogenform gebogen sein, und die Innenschiene ist in einer virtuellen Ebene senkrecht zu dem Bodenwandabschnitt der Innenschiene in der Kreisbogenform gebogen.

[0011] Die Innenschiene hat eine Querschnittsform, die einer umgekehrten Querschnittsform der Außenschiene entspricht, und die Innenschiene ist an der Außenschiene angepasst, um dadurch eine Wälzkörperrollbahn dazwischen zu definieren.

[0012] Die Wälzkörper können Kugeln sein.

[0013] Die körperseitige Schiene und die gegenstandseitige Schiene können jeweils einen zu dem kreisbogenförmigen Abschnitt verlaufenden geradlinigen Abschnitt aufweisen.

[0014] Die kreisbogenförmige Ortskurve kann einen vorbestimmten Krümmungsradius haben.

[0015] Ferner wird angemerkt, dass die Gleitschiene auf zweierlei Weise gebogen sein kann, d.h. einerseits in einer so genannten horizontal gebogenen Schwertform und andererseits in einer so genannten vertikal gebogenen Ringform. Bei der horizontal gebogenen Schwertform ist die Außenschiene in einer virtuellen Ebene des Bodenwandabschnitts der Außenschiene in der Kreisbogenform gebogen, und die Innenschiene ist auch in einer virtuellen Ebene des Bodenwandabschnitts der Innenschiene in der Kreisbogenform gebogen. Andererseits ist bei der vertikal gebogenen Ringform die Außenschiene in einer virtuellen Ebene senkrecht zu der Ebene des Bodenwandabschnitts der Außenschiene in der Kreisbogenform gebogen, und die Innenschiene ist auch in einer virtuellen Ebene senkrecht zu der Ebene des Bodenwandabschnitts der Innenwand in der Kreisbogenform gebogen.

[0016] Gemäß der oben genannte Struktur der Gleitschieneneinheit kann der auszuziehende Gegenstand, wie eine Schublade für Möbel, ein Schreibtisch oder dergleichen, anders als entlang einer herkömmlichen geradlinigen Ortskurve entlang der kreisbogenförmigen Ortskurve ausgezogen werden. Daher ist es möglich, die Gleitschiene an dem Körper, in welchem der Gegenstand verschiebbar untergebracht ist, in unterschiedlicher Weise anzubringen, und zum Beispiel kann die Schublade entlang der kreisbogenförmigen Ortskurve in der vertikalen Ebene oder in der horizontalen Ebene ausgezogen werden, was vorteilhaft ist.

Ausführungsbeispiel

[0017] Die Erfindung wird mit Bezug auf die Zeichnung näher erläutert. In der Zeichnung zeigen:

[0018] **Fig.** 1 eine Gleitschieneneinheit nach einer ersten Ausführungsform der Erfindung in einem Zustand, in dem eine Innenschiene in eine Außenschiene eingeschoben ist, wobei **Fig.** 1A eine Draufsicht der Gleitschieneneinheit, **Fig.** 1B eine Seitenansicht der Gleitschieneneinheit, und **Fig.** 1C eine Ansicht in Richtung des Pfeils IC in **Fig.** 1A ist;

[0019] **Fig.** 2 die Gleitschieneneinheit aus **Fig.** 1 in einem Zustand, in dem die Innenschiene aus der Außenschiene herausgezogen ist, wobei **Fig.** 2A eine Draufsicht der Gleitschieneneinheit und **Fig.** 2B eine Seitenansicht der Gleitschieneneinheit ist;

[0020] **Fig.** 3 eine Gleitschieneneinheit nach einer zweiten Ausführungsform der Erfindung in einem Zustand, in dem die Innenschiene in die Außenschiene eingeschoben ist, wobei **Fig.** 3A eine Draufsicht der Gleitschieneneinheit, **Fig.** 3B eine Seitenansicht der Gleitschieneneinheit, und **Fig.** 3C eine Ansicht in Richtung des Pfeils IIIC in **Fig.** 3A ist;

[0021] **Fig.** 4 die Gleitschieneneinheit aus **Fig.** 3 in einem Zustand, in dem die Innenschiene aus der Außenschiene herausgezogen ist, wobei **Fig.** 4A eine Draufsicht der Gleitschieneneinheit und **Fig.** 4B eine Seitenansicht der Gleitschieneneinheit ist;

[0022] **Fig.** 5 eine Ansicht, aus der das Biegen einer Innenschiene und einer Außenschiene der Gleitschieneneinheit mittels einer Rollenbiegemaschine ersichtlich ist;

[0023] **Fig.** 6 eine schematische Ansicht der Abfolge beim Biegen der Außenschiene und der Innenschiene mittels eines Rollenbiegeverfahrens;

[0024] **Fig.** 7 eine Gleitschieneneinheit in einem Zustand, in dem ein Schubfach entlang einer kreisbogenförmigen Ortskurve in einer horizontalen Ebene aus einem Körper herausgezogen ist, wobei **Fig.** 7A eine Draufsicht und **Fig.** 7B eine Vorderansicht ist;

[0025] **Fig.** 8 eine Draufsicht einer anderen Gleitschieneneinheit in einem Zustand, in dem ein Schubfach entlang einer kreisbogenförmigen Ortskurve in einer horizontalen Ebene aus einem Körper herausgezogen ist;

[0026] **Fig.** 9 ein Beispiel, bei dem eine Schublade mit einer üblichen Struktur entlang einer kreisbogenförmigen Ortskurve in einer horizontalen Ebene aus einem Körper herausgezogen wird, wobei **Fig.** 9A eine Gleitschieneneinheit der horizontal gebogenen Ringform und **Fig.** 9B eine Gleitschieneneinheit der horizontal gebogenen Schwertform zeigt;

[0027] **Fig.** 10 ein Beispiel, bei dem die Schublade entlang einer kreisbogenförmigen Ortskurve in einer vertikalen Ebene aus einem Körper herausgezogen wird, wobei **Fig.** 10A eine Seitenansicht im Zustand der eingeschobenen Schublade, **Fig.** 10B eine Seitenansicht im Zustand der herausgezogenen Schublade, und **Fig.** 10C eine Vorderansicht im Zustand der eingeschobenen Schublade zeigt;

[0028] **Fig.** 11 eine Seitenansicht eines Beispiels, bei dem die Schublade entlang der kreisbogenförmigen Ortskurve in der vertikalen Ebene aus einem Körper herausgezogen wird;

[0029] **Fig.** 12 ein Beispiel, bei dem ein Fach entlang einer kreisbogenförmigen Ortskurve in einer vertikalen Ebene aus einem Körper herausgezogen wird, wobei **Fig.** 12A eine Seitenansicht vor dem Herausziehen des Faches, **Fig.** 12B eine Seitenansicht während des Herausziehens des Faches, und **Fig.** 12C eine Seitenansicht nach dem Herausziehen des Faches zeigt;

[0030] **Fig.** 13 ein Beispiel, bei dem eine geradlinige Gleitschiene und eine kreisbogenförmige Gleitschiene miteinander kombiniert sind, wobei **Fig.** 13A eine Seitenansicht vor dem Herausziehen einer Schublade, **Fig.** 13B eine Seitenansicht während des Herausziehens der Schublade, und **Fig.** 13C eine Seitenansicht nach dem Herausziehen der Schublade zeigt; und

[0031] **Fig.** 14 ein anderes Beispiel, bei dem eine geradlinige Gleitschiene und eine kreisbogenförmige Gleitschiene miteinander kombiniert sind, wobei **Fig.** 14A eine Seitenansicht vor dem Herausziehen einer Schublade, **Fig.** 14B eine Seitenansicht während des Herausziehens der Schublade, und **Fig.** 14C eine Seitenansicht nach dem Herausziehen der Schublade zeigt.

[0032] Mit Bezug auf die Zeichnung werden bevorzugte Ausführungsformen einer Gleitschieneneinheit gemäß der Erfindung beschrieben.

[0033] Zuerst ist mit Bezug auf **Fig.** 1 und 2 eine Gleitschieneneinheit nach einer ersten Ausführungsform der Erfindung insgesamt ein Metallgegenstand zum sanften Öffnen oder Schließen eines ausziehbaren Gegenstandes, und beispielsweise ist die Gleitschieneneinheit an einer Schublade einer Systemküche, eines Spülschrankes, eines Möbelstücks, wie eines Fächerschrankes, eines Garderobenschrankes, Systemmöbeln, oder dergleichen angebracht. Die Gleitschieneneinheit weist eine Außenschiene **1**, eine Innenschiene **2** und eine Anzahl von Kugeln (Wälzkörper) **3** auf, die zwischen der Außenschiene und der Innenschiene **1** und **2** angeordnet sind, um an diesen entlang zu rollen. **Fig.** 1 zeigt einen Zustand, in dem die Innenschiene **2** in die Außenschiene **1** eingeschoben ist, und **Fig.** 2 zeigt einen Zustand, in dem die Innenschiene **2** aus der Außenschiene herausgezogen ist.

[0034] Die Außenschiene **1** hat einen kanalförmigen Querschnitt und weist einen Bodenwandabschnitt **1a**, der sich in Längsrichtung erstreckt, und ein Paar Seitenwandabschnitte **1b** auf, die an beiden Längsseiten des Bodenwandabschnitts **1a** quer zur Längsrichtung gebogen sind. Die beiden Seitenwandabschnitte **1b** haben jeweils einen nach außen vorstehenden kreisbogenförmigen Querschnitt. An den einander gegenüberliegenden Innenwandflächen der Seitenwandabschnitte **1b** sind Kugelrollabschnitte (Wälzkörperrollabschnitte) **5** ausgebildet, die sich in Längsrichtung der Außenschiene **1** erstrecken.

[0035] Bei der erläuterten Ausführungsform ist die Außenschiene **1** in einer virtuellen Ebene des Bodenwandabschnitts **1a** (d.h. in der in **Fig.** 1A und 2A gezeigten Ebene) kreisbogenförmig mit einem konstanten Krümmungsradius in eine so genannte horizontal gebogene Schwertform gebogen. In anderen Worten ist die Außenschiene **1** um eine Achse senkrecht zu dem Bodenwandabschnitt **1a** gebogen. Dementsprechend sind die beiden einander gegenüberliegenden Seitenwandabschnitte **1b** und auch die beiden einander gegenüberliegenden nutförmigen Kugelrollabschnitte **5** mit einem durchgängig konstanten Abstand voneinander kreisbogenförmig gekrümmt. In dem Bodenwandabschnitt **1a** der Außenschiene **1** sind eine Mehrzahl von Öffnungen **7** (siehe **Fig.** 4) mit einem in Längsrichtung konstanten Abstand voneinander ausgebildet, in welche Befestigungsmittel, wie Schrauben oder dergleichen, eingesetzt werden, um dadurch die Außenschiene **1** an der Schublade oder dem Körper, wie einem Möbelstück, zu befestigen.

[0036] An dem einen Längsendabschnitt der Außenschiene **1** ist ein Schienenanschlag **8** (siehe **Fig.** 2) ausgebildet, der durch Biegen des Endabschnitts der Außenschiene **1** im rechten Winkel zu dem Bodenwandabschnitt **1a** geformt wird. Der Schienenanschlag **8** stößt gegen die Innenschiene **2**, wenn diese in Einschubrichtung A bewegt wird, um die Innenschiene **2** in deren Einschubzustand zu stoppen, wie in **Fig.** 1 gezeigt ist. Wie in **Fig.** 2A gezeigt ist, ist in der Nähe des Schienenanschlags **8** ein Rückhalteanschlag **9** ausgebildet, der aus flachen vorstehenden oder vertieften Abschnitten zusammengesetzt ist, die zum Beispiel durch einen Prägevorgang geformt werden. Der Rückhalteanschlag **9** stößt gegen einen Rückhalter **10** der Innenschiene **2**, um den Rückhalter **10** in dessen Einschubzustand zu stoppen, wie in **Fig.** 1 gezeigt ist.

[0037] An dem anderen Längsendabschnitt der Außenschiene **1** sind Führungskugeln **11** angeordnet, die aus Kunststoff oder dergleichen sind und die aus der Außenschiene **1** herausgezogene Innenschiene **2** führen. Die Führungskugeln **11** sind in den an der Außenschiene **1** ausgebildeten Kugelrollabschnitten **5** eingepasst und werden von Haltern **12** abgestützt, die an den Innenabschnitten der Außenschiene **1** derart befestigt sind, dass sie in Bezug auf die Außenschiene **1** nicht gleiten.

[0038] Die Innenschiene **2** hat an ihren beiden Längsseiten eine zu dem Nutquerschnitt der Außenschiene **1** umgekehrte Nutquerschnittsform und ist in dem Innenabschnitt der Außenschiene **1** eingepasst, um relativ zu diesem zu gleiten. Die Innenschiene **2** hat in Längsrichtung im Wesentlichen dieselbe Länge wie die Außenschiene **1**.

[0039] Die Innenschiene **2** hat einen kanalförmigen Querschnitt und weist einen Bodenwandabschnitt **2a**, der sich in Längsrichtung erstreckt, und ein Paar Seitenwandabschnitte **2b** auf, die an beiden Längsseiten des Bodenwandabschnitts **2a** quer zur Längsrichtung gebogen sind. Die beiden Seitenwandabschnitte **2b** haben jeweils einen nach innen vorstehenden kreisbogenförmigen Querschnitt. An den einander gegenüberliegenden Außenwandflächen der Seitenwandabschnitte **2b** sind Kugelrollabschnitte (Wälzkörperrollabschnitte) **13** ausgebildet, die sich in Längsrichtung der Innenschiene **2** erstrecken.

[0040] Bei der erläuterten Ausführungsform ist die Innenschiene **2** in einer virtuellen Ebene des Bodenwandabschnitts **2a** kreisbogenförmig mit einem konstanten Krümmungsradius in eine so genannte horizontal gebogene Schwertform gebogen. Dementsprechend sind die beiden einander gegenüberliegenden Seitenwandabschnitte **2b** und auch die beiden einander gegenüberliegenden Kugelrollabschnitte **13** mit einem durchgängig konstanten Abstand voneinander kreisbogenförmig gekrümmt. In dem Bodenwandabschnitt **2a** der Innenschiene **2** sind eine Mehrzahl von Öffnungen **15** (siehe **Fig.** 4) mit einem in Längsrichtung konstanten Abstand voneinander ausgebildet, in welche Befestigungsmittel, wie Schrauben oder dergleichen, eingesetzt werden, um dadurch die Innenschiene **2** an der Schublade oder dem Körper, wie einem Möbelstück, zu befestigen.

[0041] An dem einen Längsendabschnitt der Innenschiene **2**, der dem einen Längsendabschnitt der Außenschiene **1** entspricht, an dem der Schienenanschlag **8** ausgebildet ist, ist eine Klaue **16** ausgebildet, die zu dem Bodenwandabschnitt **1a** der Außenschiene **1** hin vorsteht. Die Klaue **16** ist mit dem Schienenanschlag **8** in Eingriff zu bringen, um die Bewegung der Innenschiene **2** in deren Einschubzustand zu stoppen, wie in **Fig.** 1 gezeigt ist. Wie in **Fig.** 2A gezeigt ist, ist an dem anderen Längsendabschnitt des Bodenwandabschnitts **2a** der Innenschiene **2** ein Schubladenanschlag (nicht gezeigt) vorgesehen, um mit einer Klaue (nicht gezeigt) zu kollidieren, die an dem jeweiligen Halter **12** der Außenschiene **1** ausgebildet ist, um dadurch die Bewegung der Innenschiene **2** in dessen Auszugzustand (**Fig.** 2) zu stoppen.

[0042] Die Kugeln **3** als Wälzkörper sind zwischen den Kugelrollabschnitten **13**, die an den Seitenwandabschnitten **2b** der Innenschiene **2** ausgebildet sind, und den Kugelrollabschnitten **5** angeordnet, die an den Seitenwandabschnitten **1b** der Außenschiene **1** ausgebildet sind. Eine Reihe der Kugeln **3** werden gehalten, um mittels des Rückhalters **10** gerollt zu werden.

[0043] Der Rückhalter **10** hat eine geringe Dicke und weist einen Bodenwandabschnitt **10a**, der sich in dessen Längsrichtung erstreckt, und ein Paar Armabschnitte **10b** auf, die an beiden Längsseiten des Bodenwandabschnitts **10a** quer zur Längsrichtung gebogen sind. Eine Reihe von Kugeln **3** werden zwischen den mit dem Bodenwandabschnitt **10a** verbundenen Armabschnitten **10b** und den Kugelrollabschnitten **5** der Außenschiene **1** gehalten, so dass die Kugeln **3** aus diesen Abschnitten selbst dann nicht herausfallen, wenn die Innenschiene **2** von der Außenschiene **1** demontiert wird. Der Bodenwandabschnitt **10a** des Rückhalters **10** ist mit einem umgekehrten Kanalabschnitt **18**, der sich in Längsrichtung in der Mitte des Rückhalters **10** erstreckt, und Verbindungsabschnitten **20** versehen, die Seitenwandabschnitte **19** des umgekehrten Kanalabschnitts **18** und die jeweiligen Armabschnitte **10b** des Rückhalters **10** miteinander verbinden. Der umgekehrte Kanalabschnitt **18** dient zur Verhinderung der gegenseitigen Beeinflussung des Rückhalters **10** mit einem Schraubenkopf oder dergleichen einer Schraube beim Befestigen der Außenschiene **1** an der Schublade oder dem Körper und zur Erhöhung der Festigkeit des Rückhalters **10**. In dem umgekehrten Kanalabschnitt **18** sind Öffnungen **21** in einem in Längsrichtung konstanten Abstand voneinander ausgebildet, um die Pressbearbeitung des Rückhalters **10** zu erleichtern.

[0044] Wie oben erwähnt, werden eine Anzahl von Kugeln **3** von den seitlichen Armabschnitten **10b** des Rückhalters **10** gehalten, um in dessen Längsrichtung in gleichen Abständen voneinander gerollt zu werden. Die Armabschnitte **10b** sind parallel zueinander und beiderseits und senkrecht zu dem umgekehrten Kanalabschnitt **18** angeordnet. In den Armabschnitten **10b** sind Öffnungen zum Aufnehmen der Kugeln **3** ausgebildet, wobei der Durchmesser der Öffnungen etwas kleiner als der Durchmesser der Kugeln **3** ist.

[0045] Ferner sind in den Armabschnitten **10b** und den Verbindungsabschnitten **20** des Rückhalters **10** Ausschnitte **22** zwischen einander benachbarten Kugeln **3** ausgebildet. In den Ausschnitten **22** sind Schlitze **23** ausgebildet, die sich quer zur Längsrichtung von den Ausschnitten **22** zu einem der Seitenwandabschnitte **19** und dem Bodenabschnitt des umgekehrten Kanalabschnitts **18** durch diese hindurch erstrecken. Die Schlitze **23** sind derart ausgebildet, dass der Rückhalter **10** leicht in Kreisbogenform gebogen werden kann, um mit der Kreisbogenkurve der Außenschiene **1** übereinzustimmen. Das heißt, wenn beabsichtigt ist, den Rückhalter **10** in einer Ebene des Bodenabschnitts des umgekehrten Kanalabschnitts **18** zu biegen, wird ein großes Flächenträgheitsmoment verursacht, wodurch der Rückhalter **10** nicht leicht gebogen werden kann. Jedoch werden bei der Struktur mit den Schlitzen **23** jeweils nur ein Teil der Seitenwandabschnitte **19** des umgekehrten Kanalabschnitts **18** und ein Teil des Verbindungsabschnitts **20** gebogen, so dass der Biegevorgang leicht durchgeführt werden kann.

[0046] Ferner ist es möglich, einen Rückhalter **10** mit einer gekrümmten Struktur in Übereinstimmung mit der Krümmung der Außenschiene **1** mittels eines Pressvorgangs ohne Formung derartiger Schlitze **23** herzustellen. Der Rückhalter **10** kann aus Kunststoff mittels eines Kunststoffformungsvorgangs gebildet werden. Außerdem ist die Form des Rückhalters **10** nicht auf die oben beschriebene Form beschränkt, sondern der Rückhalter **10** kann auch verschiedene andere Formen annehmen, soweit diese mit einer Haltefunktion für die Kugeln **3** versehen ist.

[0047] Wenn eine äußere Kraft in Längsrichtung auf die Innenschiene **2** ausgeübt wird, wenn die Außenschiene **1** befestigt ist, rollen die Kugeln **3** ab, und die Innenschiene **2** gleitet in dessen Längsrichtung in Bezug auf die Außenschiene **1**. In diesem Moment rollen die Kugeln **3** in dem Raum zwischen dem Kugelrollabschnitt **5** der Außenschiene **1** und dem Kugelrollabschnitt **13** der Innenschiene **2**, um sich über eine Strecke zu bewegen, die der Hälfte der Verschiebung der Innenschiene **2** entspricht. Der Rückhalter **10** bewegt sich auch über eine Strecke, die gleich der Verschiebung der jeweiligen Kugel **3** ist. Andererseits behält die Führungskugel **11** ihre konstante Position an der Außenschiene **1**. Daher gleitet die Innenschiene **2** in Bezug auf die Außenschiene **1**, während sie durch die Führungskugel **11** und die von dem Rückhalter **10** gehaltene Kugel **3** gehalten wird.

[0048] Die Innenschiene **2** und die Außenschiene **1** können in deren Längsrichtung relativ zueinander gleiten. Da die Außenschiene **1** und die Innenschiene **2** in einer Kreisbogenform gebogen sind, wird die Innenschiene **2**, und daher die Schublade auch derart bewegt, dass sie eine kreisbogenförmige Ortskurve beschreibt. Daher wird, wenn zum Beispiel die Gleitschieneneinheit mit der Schwertform an einem Abschnitt zwischen der Seitenfläche der Schublade und der Seitenfläche des Körpers montiert ist, die Schublade derart bewegt, dass sie die kreisbogenförmige Ortskurve (Spur oder Bahn) in der vertikalen Ebene beschreibt.

[0049] **Fig.** 3 und 4 zeigen eine Gleitschieneneinheit nach einer zweiten Ausführungsform der Erfindung. **Fig.** 3 zeigt den Zustand, in dem die Innenschiene **2** in die Außenschiene **1** eingeschoben ist, während **Fig.** 4 den Zustand zeigt, in dem die Innenschiene **2** aus der Außenschiene **1** herausgezogen ist.

[0050] Die zweite Ausführungsform unterscheidet sich von der ersten Ausführungsform in der Krümmungsstruktur der Außenschiene **1** und der Innenschiene **2**, während die anderen Strukturen im Wesentlichen dieselben wie die der ersten Ausführungsform sind, so dass gleiche Teile mit denselben Bezugszeichen bezeichnet sind und deren Erläuterung weggelassen wird. Bei dieser Ausführungsform sind die Außenschiene **1** und die Innenschiene **2** jeweils in einer virtuellen Ebene senkrecht zu dem Bodenwandabschnitt **1a** der Außenschiene **1** bzw. zu dem Bodenwandabschnitt **2a** der Innenschiene **2** (d.h. in der in **Fig.** 3B und 4B gezeigten Ebene) kreisbogenförmig mit einem konstanten Krümmungsradius in eine so genannte vertikal gebogene Ringform gebogen. In anderen Worten sind die Außenschiene **1** und die Innenschiene **2** um eine Achse parallel zu den Bodenwandabschnitten **1a** und **2a** der Außenschiene **1** bzw. der Innenschiene **2** gebogen. Ferner sind die beiden einander gegenüberliegenden Seitenwandabschnitte **1b** und **2b** und auch die beiden einander gegenüberliegenden Kugelrollabschnitt **5** und **13** der Außenschiene **1** bzw. der Innenschiene **2** jeweils mit einem durchgängig konstanten Abstand voneinander kreisbogenförmig gekrümmt.

[0051] Der Rückhalter **10** ist in Übereinstimmung mit der Biegung der Außenschiene **1** in einer Ebene senkrecht zu dem Bodenabschnitt des umgekehrten Kanalabschnitts **18** des Rückhalters **10** gebogen. Bei dieser Struktur ist im Vergleich zu dem Rückhalter **10** der ersten Ausführungsform das Flächenträgheitsmoment des Rückhalters **10** gering. In dieser Weise ist es möglich, Schlitze **23** zu bilden, die sich quer zur Längsrichtung von den Ausschnitten **22** in den Verbindungsabschnitten **20** des Rückhalters **10** zu einem der Seitenwandabschnitte **19** des umgekehrten Kanalabschnitts **18** durch diesen hindurch erstrecken. In diesem Falle ist es möglich, das Material, die Form usw. des Rückhalters **10** in derselben Weise wie bei der ersten Ausführungsform zu verändern.

[0052] Bei der zweiten Ausführungsform sind die Innenschiene **2** und die Außenschiene **1** in deren Längsrichtung ebenfalls relativ zueinander verschiebbar. Da die Außenschiene **1** und die Innenschiene **2** in eine Kreisbogenform gebogen sind, hat auch die Ortskurve der Innenschiene **2**, und daher die Ortskurve der Schublade eine Kreisbogenform. Zum Beispiel beschreibt in dem Falle, in dem eine Gleitschieneneinheit mit der vertikal gebogenen Ringform an einem Abschnitt zwischen dem Seitenabschnitt der Schublade und dem Seitenabschnitt des Körpers angebracht ist, die Schublade eine kreisbogenförmige Ortskurve (Spur oder Bahn) in der horizontalen Ebene.

[0053] Im Folgenden wird ein Verfahren zur Herstellung der Außenschiene **1** und der Innenschiene **2** der Gleitschieneneinheit gemäß der oben genannten

Struktur beschrieben. **Fig.** 5 zeigt ein Beispiel der Herstellung der Gleitschieneneinheit unter Verwendung einer Bearbeitungsmaschine, die als Rollenbiegemaschine (Winkelbiegemaschine) bezeichnet wird, zum Biegen der Außenschiene **1** und der Innenschiene **2**.

[0054] Zuerst werden eine Außenschiene **1** und eine Innenschiene **2** angefertigt, die vorläufig mit einer geradlinigen Form ausgebildet sind. In diesem Stadium der Herstellung sind die Außenschiene **1** und die Innenschiene **2** bereits mit einem kanalförmigen Abschnitt geformt. Als nächstes werden eine Mehrzahl von Rollen **31**, **32** und **33** vorbereitet, deren Achsen parallel zueinander angeordnet sind, und die geradlinige Außenschiene **1** wird durch mehrmalige Hin- und Herbewegung durch einen Spalt zwischen der Rolle **33** und der Rolle **32** und dann einen Spalt zwischen der Rolle **33** und der Rolle **31** hindurch mittels Drehung der Rollen **21**, **32** und **33** gerollt, wie in **Fig.** 5 gezeigt ist, um dadurch die Außenschiene **1** in eine Kreisform zu biegen. In derselben Weise wird die geradlinige Innenschiene **2** mehrmals zwischen den Rollen **33** und **32** und den Rollen **33** und **31** mittels Drehung der Rollen **31**, **32** und **33** hin- und hergehend gerollt, um dadurch die Innenschiene **2** in eine Kreisform zu biegen. Es ist natürlich auch möglich, zuerst die Innenschiene **2** und dann die Außenschiene **1** zu biegen.

[0055] Die Außenschiene **1** und die Innenschiene **2** haben jeweils einen kanalförmigen Querschnitt, so dass die Gefahr besteht, dass die Seitenwandabschnitte **1b** und **2b** der Außenschiene **1** bzw. der Innenschiene **2** beim Biegen mittels des Rollenbiegevorgangs nach innen gebogen werden können. Wenn die Seitenwandabschnitte **1b** und **2b** nach innen gebogen werden, besteht auch die Gefahr, dass es schwierig ist, die Kugeln **3** zwischen dem Kugelrollabschnitt **5** des Seitenwandabschnitts **1b** der Außenschiene **1** und dem Kugelrollabschnitt **13** des Seitenwandabschnitts **2b** der Innenschiene **2** anzuordnen. Um einer solchen Gefahr vorzubeugen, wird ein Einschluss- oder Zwischenteil mit einer der Form der Nut des Kanals der Außenschiene **1** entsprechenden Form in die Außenschiene **1** eingepasst, um die Reduzierung des Abstandes zwischen den beiden einander gegenüberliegenden Seitenwandabschnitten **1b** der Außenschiene **1** beim Passieren der Spalte zwischen den Rollen **33** und **32** und den Rollen **33** und **31** zu unterdrücken. In der gleichen Weise wird ein Einschluss- oder Zwischenteil mit einer der Form des Kanals der Innenschiene **2** entsprechenden Form in die Innenschiene **2** eingepasst, um die Reduzierung des Abstandes zwischen den einander gegenüberliegenden Seitenwandabschnitten **2b** der Innenschiene **2** beim Passieren der Spalte zwischen den Rollen **33** und **32** und den Rollen **33** und **31** zu unterdrücken. Die Einschluss- oder Zwischenteile sind aus weichem Kunststoff, wie Polyvinylchlorid, geformt und können auch bei dem Rollenbiegevorgang in derselben Weise wie die Außenschiene **1** und die Innenschiene **2** gebogen werden.

[0056] Wie oben beschrieben, können unter Verwendung der Rollenbiegemaschine die Außenschiene **1** und die Innenschiene **2** mit verschiedenen Größen und Biegekrümmungsradien hergestellt werden.

[0057] **Fig.** 6 zeigt ein Beispiel der Herstellung der Außenschiene und der Innenschiene mittels eines Rollenbiegeverfahrens. In diesem Beispiel wird ein flaches Teil zwischen einer Mehrzahl von Paaren von Profilrollen **34–37** geführt, und entsprechend dem Passieren von der vorderen Rolle zu den nachfolgenden Rollen wird die Außenschiene **1** oder die Innenschiene **2** allmählich geformt, um einen kanalförmigen Querschnitt zu schaffen. Während dieses Rollvorgangs wird die Außenschiene **1** oder die Innenschiene **2** derart gebogen, dass die Innenschiene **2** die kreisbogenförmige Ortskurve in Bezug auf die Außenschiene **1** bildet. Mit der kreisbogenförmigen Anordnung der Mehrzahl von Profilrollen **34–37** in der senkrechten Ebene, wie in **Fig.** 6 gezeigt ist, kann die vertikal gebogene Ringform der Außenschiene **1** oder der Innenschiene **2** unter Bildung der kanalförmigen Struktur geschaffen werden. Ferner kann mit der kreisbogenförmigen Anordnung der Mehrzahl von Profilrollen **34–37** in der horizontalen Ebene die horizontal gebogene Schwertform der Außenschiene **1** oder der Innenschiene **2** geschaffen werden.

[0058] Die Außenschiene **1** und die Innenschiene **2** können mittels eines anderen Verfahrens als dem oben genannten Verfahren hergestellt werden, wie zum Beispiel mittels eines Pressverfahrens, welches für die Herstellung einer Schiene mit einer vorbestimmten Länge und einem vorbestimmten Krümmungsradius geeignet ist.

[0059] Die oben beschriebene Gleitschieneneinheit nach der ersten und der zweiten Ausführungsform kann in der folgenden Weise verwendet werden. **Fig.** 7 zeigt ein Beispiel, bei dem ein Schubfach entlang einer kreisbogenförmigen Ortskurve in einer horizontalen Ebene aus einem Körper herausgezogen wird, wobei **Fig.** 7A eine Draufsicht und **Fig.** 7B eine Vorderansicht ist. Eine Gleitschieneneinheit **42** ist an der Seitenfläche einer Schublade **40**, wie eines Schrankfaches, und an der Seitenfläche eines Körpers **41** montiert, um die Schublade **40** in Bezug auf den Körper **41** gleitend zu bewegen. Wenn eine Bedienperson die Schublade **40** aus dem Körper **41** herauszieht, bewegt sich die Schublade **40** entlang der kreisbogenförmigen Ortskurve in der horizontalen Ebene. In diesem Beispiel ist anzumerken, dass die offene Seite **40a** der herausgezogenen Schublade **40** von der Bedienperson leicht eingesehen werden kann.

[0060] **Fig.** 8 zeigt auch ein Beispiel in Draufsicht, bei dem das Schubfach **40** entlang einer kreisbogenförmigen Ortskurve in einer horizontalen Ebene aus einem Körper herausgezogen wird. In diesem Beispiel ist die Gleitschieneneinheit **42** auch an der Seitenfläche der Schublade **40**, wie eines Schrankfaches, und an der Seitenfläche des Körpers **41** montiert. Wenn eine Bedienperson die Schublade **40** aus dem Körper **41** herauszieht, bewegt sich die Schublade **40** entlang der kreisbogenförmigen Ortskurve in der horizontalen Ebene, um ein in der geradlinigen Bahn vorhandenes Hindernis **50** zu umgehen, wodurch eine Kollision der Schublade **40** mit dem Hindernis **50** verhindert wird.

[0061] **Fig.** 9 zeigt ein Beispiel, bei dem eine Schublade **44** der üblichen Art mit offener Oberseite entlang einer kreisbogenförmigen Ortskurve in einer horizontalen Ebene aus einem Körper herausgezogen wird, wobei in **Fig.** 9A eine Gleitschieneneinheit **42** der horizontal gebogenen Ringform an den Seitenflächen der Schublade **44** und des Körpers **41** montiert ist und in **Fig.** 9B eine Gleitschieneneinheit **43** der horizontal gebogenen Schwertform an den unteren Flächen der Schublade **44** und des Körpers **41** montiert ist.

[0062] In diesem Beispiel kann, wenn die Bedienperson die Schublade **44** aus einer Position von dem vorderen Seitenabschnitt der Schublade **44** weg aus dem Körper **41** herauszieht und die Schublade **44** derart ausgebildet ist, dass sie entlang der kreisbogenförmigen Ortskurve ausziehbar ist, die Bedienperson die Schublade **44** so leicht aus dem Körper **41** herausziehen, wie eine Tür nach vorn zu öffnen ist. Dieses Beispiel kann besonders in dem Falle angewendet werden, wo die Schublade **44** sehr nahe zu einer Wandfläche vorgesehen ist, d.h. die Bedienperson kann, wenn sie von der Wandfläche weg ist, die Schublade **44** aus dem Körper **41** herausziehen. Wie oben erwähnt, kann durch die Gestaltung der Schublade mit einer kreisbogenförmigen Ortskurve im Vergleich zu der üblichen geradlinigen Ortskurve der Freiheitsgrad für die Gestaltung der Schublade und deren nutzbaren Bereichs beträchtlich erweitert werden.

[0063] **Fig.** 10 zeigt ein Beispiel, bei dem die Schublade entlang einer kreisbogenförmigen Ortskurve in einer vertikalen Ebene aus einem Körper herausgezogen werden kann. In diesem Beispiel ist die Gleitschieneneinheit **43** in der vertikal gebogenen Schwertform zwischen der Seitenfläche der Schublade **44** und der Seitenfläche des Körpers **41** montiert. **Fig.** 10A zeigt eine Seitenansicht im Zustand der eingeschobenen Schublade **44**, **Fig.** 10B zeigt eine Seitenansicht im Zustand der herausgezogenen Schublade **44**, und **Fig.** 10C zeigt eine Vorderansicht im Zustand der eingeschobenen Schublade **44**. In diesem Beispiel kann, wenn die Schublade **44** aus dem Körper **41** herausgezogen ist, ein großer Spalt in vertikaler Richtung zwischen der Schublade **44** und dem geöffneten Seitenabschnitt des Körpers **41**, in dem die Schublade **44** aufgenommen wird, vorgesehen sein, so dass die Schublade **44** in eine nach unten geneigte Position herausgezogen werden kann, wodurch Gegenstände und dergleichen leicht in die Schublade **44** gelegt oder aus dieser herausgenommen werden können und die Bedienperson kann die Innenseite des Schubfaches **44** leicht einsehen kann.

[0064] **Fig.** 11 zeigt auch ein Beispiel, bei dem die Schublade **44** entlang der kreisbogenförmigen Ortskurve in der vertikalen Ebene aus einem Körper herausgezogen wird. In diesem Beispiel ist die Gleitschieneneinheit **42** in vertikal gebogener Ringform zwischen der unteren Fläche der Schublade **44** und der unteren Fläche des Körpers **41** montiert. In diesem Beispiel kann, wenn die Schublade **44** aus dem Körper **41** herausgezogen wird, ein großer Spalt in vertikaler Richtung zwischen der Schublade **44** und dem geöffneten Seitenabschnitt des Körpers **41**, in dem die Schublade **44** aufgenommen wird, vorgesehen sein, so dass die Schublade **44** in eine nach unten geneigte Position herausgezogen werden kann, wodurch Gegenstände und dergleichen leicht in die Schublade **44** gelegt oder aus dieser herausgenommen werden können und die Bedienperson die Innenseite des Schubfaches **44** leicht einsehen kann.

[0065] **Fig.** 12 zeigt ein Beispiel, bei dem ein Fach **45** entlang einer kreisbogenförmigen Ortskurve in einer vertikalen Ebene aus einem Körper herausgezogen wird. In diesem Beispiel ist die Gleitschieneneinheit **43** in der vertikal gebogenen Schwertform zwischen der Seitenfläche des Faches **45** und der Seitenfläche des Körpers **41** montiert. **Fig.** 12A zeigt eine Seitenansicht vor dem Herausziehen des Faches **45**, **Fig.** 12B zeigt eine Seitenansicht während des Herausziehens des Faches **45**, und **Fig.** 12C zeigt eine Seitenansicht nach dem Herausziehen des Faches **45**. Das Fach **45** ist in dem Körper **41** in einer vertikalen Ebene positioniert und wird jedoch beim Herausziehen aus dem Körper **41** in eine horizontale Ebene positioniert. Daher kann das ausgezogene Fach **45** zum Beispiel als ein Tisch oder bei der Verwendung als Touch-Paneel zum Beispiel als eine Arbeitsplatte benutzt werden, wobei die Arbeitsplatte leicht überblickt und bedient werden kann.

[0066] **Fig.** 13 zeigt ein Beispiel einer Kombination einer geradlinigen Gleitschiene **46** mit einer kreisbogenförmigen Gleitschiene **43**. **Fig.** 13A zeigt eine Seitenansicht vor dem Herausziehen einer Schublade **44**, **Fig.** 13B zeigt eine Seitenansicht während des Herausziehens der Schublade **44**, und **Fig.** 13C zeigt eine Seitenansicht nach dem Herausziehen der Schublade **44**. In diesem Beispiel ist die kreisbogenförmige Gleitschiene **43** in vertikal gebogener Schwertform als Außenschiene oder Innenschiene mit der herkömmlichen geradlinigen Gleitschiene **46** als zugeordnete Außenschiene bzw. Innenschiene verbunden. Wenn die Schublade **44** aus der in **Fig.** 13A gezeigten Position herausgezogen wird, wird zuerst die kreisbogenförmige Gleitschiene **43** betätigt, und die Schublade **44** wird entlang der kreisbogenförmigen Ortskurve bewegt, wie in **Fig.** 13B gezeigt ist. Bei diesem Vorgang wird der Betrieb der geradlinigen Gleitschiene **46** blockiert. Wenn die Schublade **44** weiter herausgezogen wird, wird die Schublade **44** geradlinig nach unten gezogen, wie in **Fig.** 13C gezeigt ist. Dieses Beispiel kann vorzugsweise zum Beispiel bei einer Schublade einer Systemküche angewendet werden, die in einem oberen Bereich der Küche angeordnet ist, um die Schublade nach unten zu ziehen, wodurch Gegenstände leicht in die Schublade **44** eingelegt und herausgenommen werden können.

[0067] **Fig.** 14 zeigt ein Beispiel einer Kombination einer geradlinigen Gleitschiene **46** mit einer kreisbogenförmigen Gleitschiene **43**, wobei **Fig.** 14A eine Seitenansicht vor dem Herausziehen einer Schublade **44**, **Fig.** 14B eine Seitenansicht während des Herausziehens der Schublade **44**, und **Fig.** 14C eine Seitenansicht nach dem Herausziehen der Schublade **44** zeigt. In diesem Beispiel ist die kreisbogenförmige Gleitschiene **43** in vertikal gebogener Schwertform als Außenschiene oder Innenschiene mit der herkömmlichen geradlinigen Gleitschiene **46** als zugeordnete Außenschiene bzw. Innenschiene verbunden. Wenn die Schublade **44** aus der in **Fig.** 14A gezeigten Position herausgezogen wird, wird zuerst die geradlinige Gleitschiene **46** betätigt, und die Schublade **44** wird geradlinig in horizontaler Richtung bewegt, wie in **Fig.** 14B gezeigt ist. Bei diesem Vorgang wird der Betrieb der kreisbogenförmigen Gleitschiene **43** blockiert. Wenn die Schublade **44** weiter herausgezogen wird, wird die Schublade **44** entlang der kreisbogenförmigen Ortskurve nach unten gezogen, wie in **Fig.** 14C gezeigt ist. Dieses Beispiel kann vorzugsweise zum Beispiel bei einer Schublade einer Systemküche angewendet werden, die in einem oberen Bereich der Küche angeordnet ist, um die Schublade nach unten zu ziehen, wodurch Gegenstände leicht in die Schublade **44** eingelegt und herausgenommen werden können.

[0068] Ferner wird angemerkt, dass die Erfindung nicht auf die beschriebenen Ausführungsformen beschränkt ist und viele verschiedene Änderungen und Modifikationen vorgenommen werden können, ohne vom Schutzbereich der Erfindung abzuweichen. Zum Beispiel kann die Schublade mit der oben beschriebenen Struktur anders als bei Möbeln auch bei einer Tonerwechseleinrichtung einer Kopiermaschine, einer Öffnungs- und Schließeinrichtung einer Nottür oder irgendwelchen anderen Einrichtungen für Gegenstände, die herauszuziehen sind, angewendet werden. Anstelle von Kugeln können Rollen verwendet werden. Ferner kann die Kombinationsstruktur der relativ zueinander bewegbaren Außenschiene und Innenschiene auch ohne Wälzkörper, die zwischen der Außenschiene und der Innenschiene angeordnet sind, angewendet werden.

Patentansprüche

1. Gleitschieneneinheit zum Führen eines Gegenstandes (**40**), der aus einem Körper (**41**) herauszuziehen ist, in welchem der Gegenstand (**40**) gleitend aufgenommen ist, aufweisend:
eine körperseitige Schiene, die für den Körper (**41**) vorgesehen ist; und
eine gegenstandseitige Schiene, die für den Gegenstand (**40**) vorgesehen ist, um relativ zu der körperseitigen Schiene gleitend ausgezogen zu werden,
wobei die körperseitige Schiene und die gegenstandseitige Schiene jeweils einen Abschnitt aufweisen, der in Kreisbogenform derart gebogen ist, dass der Gegenstand (**40**) entlang einer kreisbogenförmigen Ortskurve ausgezogen wird.

2. Gleitschieneneinheit nach Anspruch 1, aufweisend:
eine Außenschiene (**1**), die eine der körperseitigen Schiene und der gegenstandseitigen Schiene für den herauszuziehenden Gegenstand bildet, wobei die Außenschiene (**1**) aus einem Bodenwandabschnitt (**1a**), der sich in dessen Längsrichtung in Kreisbogenform erstreckt, und einem Paar Seitenwandabschnitten (**1b**) zusammengesetzt ist, die in einer gebogenen Form quer zur Längsrichtung an beiden Längsseiten des Bodenwandabschnitts (**1a**) ausgebildet sind und sich in deren Längsrichtung in Kreisbogenform erstrecken, um dadurch einen Wälzkörperrollabschnitt (**5**) zu bilden;
eine Innenschiene (**2**), die eine andere der körperseitigen Schiene und der gegenstandseitigen Schiene bildet, um an die Außenschiene (**1**) angepasst zu werden, wobei die Innenschiene (**2**) aus einem Bodenwandabschnitt (**2a**), der sich parallel zu dem Bodenwandabschnitt (**1a**) der Außenschiene (**1**) erstreckt, und einem Paar Seitenwandabschnitten (**2b**) zusammengesetzt ist, die in einer gebogenen Form quer zur Längsrichtung an beiden Längsseiten des Bodenwandabschnitts (**2a**) ausgebildet sind und sich in deren Längsrichtung in Kreisbogenform erstrecken, um dadurch einen Wälzkörperrollabschnitt (**13**) zu bilden; und
eine Anzahl von Wälzkörpern (**3**), die zwischen dem Wälzkörperrollabschnitt (**5**) der Außenschiene (**1**) und dem Wälzkörperrollabschnitt (**13**) der Innenschiene (**2**) angeordnet sind.

3. Gleitschieneneinheit nach Anspruch 2, wobei die Außenschiene (**1**) in einer virtuellen Ebene des Bodenwandabschnitts (**1a**) der Außenschiene (**1**) in der Kreisbogenform gebogen ist, und die Innenschiene (**2**) in einer virtuellen Ebene des Boden-

wandabschnitts (**2a**) der Innenschiene (**2**) in der Kreisbogenform gebogen ist.

4. Gleitschieneneinheit nach Anspruch 2, wobei die Außenschiene (**1**) in einer virtuellen Ebene senkrecht zu dem Bodenwandabschnitt (**1a**) der Außenschiene (**1**) in der Kreisbogenform gebogen ist, und die Innenschiene (**2**) in einer virtuellen Ebene senkrecht zu dem Bodenwandabschnitt (**2a**) der Innenschiene (**2**) in der Kreisbogenform gebogen ist.

5. Gleitschieneneinheit nach Anspruch 2, wobei die Innenschiene (**2**) eine Querschnittsform hat, die einer umgekehrten Querschnittsform der Außenschiene (**1**) entspricht, und die Innenschiene (**2**) an der Außenschiene (**1**) angepasst ist, um dadurch eine Wälzkörperrollbahn dazwischen zu definieren.

6. Gleitschieneneinheit nach Anspruch 1, wobei die Wälzkörper Kugeln (**3**) sind.

7. Gleitschieneneinheit nach Anspruch 1, wobei die körperseitige Schiene (**1**) und die gegenstandseitige Schiene (**2**) jeweils einen zu dem kreisbogenförmigen Abschnitt verlaufenden geradlinigen Abschnitt aufweisen.

8. Gleitschieneneinheit nach Anspruch 1, wobei die kreisbogenförmige Ortskurve einen vorbestimmten Krümmungsradius hat.

Beschreibung

[0001] Die vorliegende Erfindung bezieht sich auf eine Kugelspindel gemäß der Präambel von Anspruch 1.

[0002] Als ein Dichtungselement einer herkömmlichen Kugelspindel sind Dichtungselemente bekannt, die an beiden Endabschnitten einer Mutter angebracht sind (siehe Japanisches Gebrauchsmuster JP 6006795U). Jedes dieser Dichtungselemente hat eine Ringform und besitzt eine innere Umfangsfläche, an der ein Vorsprung ausgebildet ist, der in eine Kugelrollnut einer Spindelwelle einpassbar ist. Ein Schlitz ist auf dem Dichtungselement so ausgebildet, dass er sich ausgehend von einem Endabschnitt der Mutter nach außen weisend in axialer Richtung der Mutter zu einem Zwischenabschnitt des Dichtungselements hin erstreckt. Indem die Dichtungselemente an beiden Endabschnitten der Mutter angebracht werden, kommen die Dichtungselemente in engen Kontakt mit den äußeren Umfangsflächen der Spindelwelle, wodurch ein Schmiermittel innerhalb der Mutter eingeschlossen wird. Indem der Schlitz auf dem Dichtungselement ausgebildet wird, streift zudem ein Randabschnitt des Schlitzes, der mit der äußeren Umfangsfläche der Spindelwelle in Kontakt ist, Fremdkörper ab, die an der Spindelwelle haften, und führt die Fremdkörper nach außerhalb der Mutter ab, wodurch verhindert wird, dass die Fremdkörper in die Mutter hinein eindringen.

[0003] Jedoch dringt bei der vorstehend beschriebenen herkömmlichen Dichtungsstruktur das Schmiermittel innerhalb der Mutter leicht in einen Spalt zwischen der Spindelwelle und den Dichtungselementen ein, und es ist zu befürchten, dass das Schmiermittel nach außen aus der Mutter ausläuft. Darüberhinaus wird auch das Schmiermittel, ebenso wie die Fremdkörper, von dem Randabschnitt des Schlitzes abgestreift werden, und aus diesem Grund wird das abgestreifte Schmiermittel nach außerhalb der Mutter abgeführt und nicht in das Innere der Mutter zurückgeführt.

[0004] Das am Nächsten kommende Dokument in Bezug auf den bisherigen Stand der Technik, EP-A-0376164, beschreibt eine Kugelspindel, die aufweist: eine Spindelwelle, an der an einer äußeren Umfangsflächen eine Kugelrollnut ausgebildet ist, eine Anzahl von Kugeln, die entlang der Kugelrollnut rollen, eine Mutter, die mit der Spindelwelle über die Kugeln und Dichtungselemente, die an beiden Endabschnitten der Mutter angeordnet sind, verschraubt ist, wobei jedes der Dichtungselemente an einer inneren Umfangsfläche mit einem spiralförmigen Vorsprung ausgebildet ist, der in die Kugelrollnut einpassbar ist, wobei ein Schmiermittel zurückhaltender Abschnitt an dem Dichtungselement ausgehend von einer in axialer Richtung der Mutter nach innen weisenden Endfläche desselben gebildet ist, und wobei der Schmiermittel zurückhaltende Abschnitt einen Schlitz aufweist, und wobei der Schmiermittel zurückhaltende Abschnitt formschlüssig Schmiermittel auffängt, das in den Spalt zwischen dem Dichtungselement und der Spindelwelle durch die Endfläche dringt und das Schmiermittel in das Innere der Mutter zurückführt, und wobei der Schlitz des Schmiermittel zurückhaltenden Abschnitts sich von der Endfläche des Dichtungselements zu einem Zwischenabschnitt desselben erstreckt, und wobei ein Fremdkörper entfernender Abschnitt an dem Dichtungselement gebildet ist, um Fremdkörper, die an einer äußeren Umfangsfläche der Spindelwelle haften, zu entfernen und die Fremdkörper nach außerhalb der Mutter abzuführen.

[0005] Die vorliegende Erfindung beabsichtigt, eine Kugelspindel bereit zu stellen, die ein Dichtungselement aufweist, das in der Lage ist, ein Schmiermittel in effizienter Weise innerhalb einer Mutter einzubehalten und zu verhindern, dass Fremdkörper in das Innere der Mutter eindringen.

[0006] Gemäß der vorliegenden Erfindung ist eine wie vorstehend definierte Kugelspindel dadurch gekennzeichnet, dass der Fremdkörper entfernende Abschnitt ein Schlitz ist, der so auf dem Dichtungselement gebildet ist, dass er sich von einer in axialer Richtung der Mutter nach außen weisenden Endfläche desselben zu einem Zwischenabschnitt desselben erstreckt.

[0007] In einer Kugelspindel der Erfindung ist der Schmiermittel zurückhaltende Abschnitt an dem Dichtungselement von einer in axialer Richtung der Mutter nach innen weisenden Endfläche desselben zu einem Zwischenabschnitt desselben ausgebildet. Daher kann das in den Spalt zwischen dem Dichtungselement und der Kugelspindel durch die Endfläche eindringende Schmiermittel formschlüssig aufgefangen werden und in den inneren Abschnitt der Mutter zurückgeführt werden. Auf diese Weise kann verhindert werden, dass das Schmiermittel innerhalb der Mutter aus der Mutter ausläuft. Da der Schmiermittel zurückhaltende Abschnitt einen Schlitz aufweist, wird das Schmiermittel durch den Randabschnitt einer Seitenfläche des Schlitzes bei Kontakt mit der Spindelwelle abgestreift und in das Innere der Mutter zurückgeführt.

[0008] Weiterhin werden, da ein Fremdkörper entfernender Abschnitt an dem Dichtungselement von einer in axialer Richtung der Mutter nach außen weisenden Endfläche desselben zu einem Zwischenabschnitt desselben gebildet ist, Fremdkörper, die an der äußeren Umfangsfläche der Spindelwelle (einschließlich einer Oberfläche der Kugelrollnut) verbleiben, entfernt und aus der Mutter heraus abgeführt.

[0009] In einer Ausführung sind Pressvorrichtungen vorgesehen, um die Dichtungselemente gegen die Spindelwelle zu pressen. Die Pressvorrichtungen stellen sicher, dass der Schmiermittel zurückhaltende Abschnitt und der Fremdkörper entfernende Abschnitt in engem Kontakt mit der Spindelwelle sind. Daher kann das Schmiermittel sicher aufgefangen werden, und die Fremdkörper können entfernt werden.

[0010] Ausführungen der vorliegenden Erfindung werden nachstehend anhand von Beispielen unter Bezugnahme auf die begleitenden Zeichnungen beschrieben, in welchen;

[0011] Fig. 1 eine Grundrissansicht einer Mutter und von Dichtungselementen einer Kugelspindel einer Ausführung der Erfindung darstellt;

[0012] Fig. 2 eine Endansicht von Fig. 1 darstellt;

[0013] Fig. 3 eine Schnittansicht von Fig. 1 darstellt;

[0014] Fig. 4 eine Endansicht eines Dichtungselements darstellt;

[0015] Fig. 5 eine Schnittansicht des Dichtungselements darstellt;

[0016] Fig. 6 eine Seitenansicht eines Rings, an den eine Feder montiert ist, darstellt; und

[0017] Fig. 7 eine Schnittansicht darstellt, die eine Spindelwelle und das Dichtungselement zeigt.

[0018] Fig. 1 bis Fig. 3 stellen eine Kugelspindel mit einer Kugelspindelmutter **1** und Dichtungselementen **2** dar. Wie bekannt ist, weist die Kugelspindel eine Spindelwelle (nicht abgebildet) auf, die eine äußere Umfangsfläche besitzt, auf der eine spiralförmige Kugelrollnut gebildet ist. Die Mutter **1** hat eine innere Umfangsfläche, an der eine spiralförmige Kugelrollnut **1a**, entgegengesetzt der an der Spindelwelle gebildeten Kugelrollnut, gebildet ist. Eine Anzahl von Kugeln (nicht abgebildet) sind zwischen der Kugelrollnut **1a** der Mutter **1** und der Kugelrollnut der Spindelwelle angeordnet und eingepasst. Wenn die Spindelwelle gedreht wird, rollen die Kugeln in dem Raum zwischen der Kugelrollnut **1a** der Mutter **1** und der Kugelrollnut der Spindelwelle. Wenn eine Kugel einen Endabschnitt der Kugelrollnut **1a** der Mutter **1** erreicht, kehrt diese durch einen an der Mutter **1** befestigte Rückführröhre **3** zu der entgegengesetzten Seite der Kugelrollnut **1a** zurück. Die Mutter **1** führt eine lineare Bewegung entlang der Spindelwelle durch Drehung derselben aus.

[0019] Ein Paar von Montagelöchern für Dichtungselemente **1b** ist an jeweiligen axialen Endabschnitten der Mutter **1** ausgebildet. Ein ringförmiges Dichtungselement **2** ist in jedes der Montagelöcher für Dichtungselemente **1b** montiert und in diesen mittels eines Sprengrings **4** befestigt. Jedes Dichtungselement **2** wird durch eine Einspritzformung eines synthetischen Harzes oder durch eine Schneidebearbeitung hergestellt, und ein spiralförmiger Vorsprung **2a** wird an der inneren Umfangsfläche des Dichtungselements **2**, das in die Kugelrollnut der Spindelwelle einpassbar ist, gebildet (siehe Fig. 3).

[0020] Wie in Fig. 3 dargestellt, sind eine Mehrzahl von Schlitzen **5** zum Zurückhalten von Schmiermittel an dem Dichtungselement **2** so gebildet, dass jeder sich von einer in axialer Richtung der Mutter **1** nach innen weisenden Endfläche **2b** desselben zu einem Zwischenabschnitt des Dichtungselements **2** erstreckt. Eine Mehrzahl von Schlitzen zum Entfernen von Fremdkörpern sind an dem Dichtungselement **2** so ausgebildet, dass jeder sich von einer in axialer Richtung der Mutter **1** nach außen weisenden Endfläche **2c** desselben zu einem Zwischenabschnitt des Dichtungselements **2** erstreckt. Die Schmiermittel zurückhaltenden Schlitze **5** können verhindern, dass Schmiermittel (zum Beispiel Fett), das den inneren Abschnitt der Mutter **1** füllt, nach außen ausläuft. Die Fremdkörper entfernenden Schlitze **6** können verhindern, dass Fremdkörper von außen in die Mutter **1** eindringen.

[0021] Fig. 4 stellt eine Endansicht der Dichtung dar und veranschaulicht die Anordnung der Schmiermittel zurückhaltenden Schlitze **5**. Jeder der Schmiermittel zurückhaltenden Schlitze **5** erstreckt sich im Wesentlichen in radialer Richtung der Spindelwelle, so dass diese als Löcher das Dichtungselement **2** von dessen innerem Umfang zu dessen äußerem Umfang hin durchdringen. Zudem stellen in Fig. 4 schräge Linienabschnitte die nachstehend beschriebenen Federn **12a** und **12b** dar. Wie dargestellt, sind die Schmiermittel zurückhaltenden Schlitze **5** an acht Abschnitten des Dichtungselements **2** mit gleicher Distanz zwischen solchen, die benachbart sind, in Umfangsrichtung angeordnet. Die acht Schmiermittel zurückhaltenden Schlitze **5** sind so gebildet, dass jeder eine Neigung (θ1) in der Drehrichtung F der Spindelwelle aufweist, und sich nach und nach in die Richtung von Pfeil F von der inneren Umfangsfläche der Spindelwelle zu der äußeren Umfangsfläche derselben hin verschiebt.

[0022] Die geneigte Ausbildung der Schmiermittel zurückhaltenden Schlitze **5** ermöglicht es, dass eine der einander gegenüber liegenden Seitenflächen **8a** und **8b** jedes Schlitzes **5** als eine Schmiermittel zurückhaltende Abstreiffläche mit einem Randabschnitt zum Abstreifen des Schmiermittels fungiert. Die Anzahl der Schmiermittel zurückhaltenden Schlitze **5** kann je nach Bedarf gewählt werden.

[0023] Fig. 5 stellt eine Schnittansicht des Dichtungselements **2** dar. Die Schmiermittel zurückhaltenden Schlitze **5** sind so gebildet, dass jeder eine Neigung (θ2) in Bezug auf die Richtung einer Achse X der Mutter **1** aufweist. Das heißt, dass in einem Fall, in dem die Mittellinie E der Kugelrollnut **9** in einem Steigungswinkel α geneigt ist, in einer vorbestimmten abgelenkten Richtung D in Bezug auf die Richtung (Richtung der Hilfslinie C), die normal in Bezug auf die Richtung der Achse X der Mutter **1** ist, die Mittellinie des Schmiermittel zurückhaltenden Schlitzes **5** von dem vorbestimmten Winkel (θ2) umfasst ist, in einer in Bezug auf die Achse X der Mutter **1** der Richtung D entgegengesetzten Richtung. Die Schmiermittel zurückhaltende Abstreiffläche **8b** ist in einem Winkel β von einer Fläche aus geneigt, die lotrecht zu der Mittellinie E der Kugelrollnut **9** ist, so dass sie das Schmiermittel in die axiale Richtung X der Mutter verschiebt und das Schmiermittel in die Mutter **1** zurückführt. Die acht Schmiermittel zurückhaltenden Schlitze sind alle mit einer Neigung (θ2) in Bezug auf die Achse X der Mutter **1** ausgebildet.

[0024] Die Fremdkörper entfernenden Schlitze **6** erstrecken sich im Wesentlichen in radialer Richtung der Spindelwelle, so dass diese als Löcher das Dichtungselement **2** von dessen innerem Umfang zu dessen äußerem Umfang hin durchdringen (siehe Fig. 2). In der veranschaulichten Ausführung sind diese Fremdkörper entfernenden Schlitze **6** ebenfalls an acht Abschnitten des Dichtungselements **2** mit gleicher Distanz zwischen solchen, die benachbart sind, in Umfangsrichtung ausgebildet. Jeder der Fremdkörper entfernenden Schlitze **6** hat eine Neigung (θ1) in der Drehrichtung F der Spindelwelle in Bezug auf die radiale Richtung der Spindelwelle. Eine der einander gegenüber liegenden Oberflächen **10a** und **10b** jedes der Schlitze **6** fungiert als eine Fremdkörper entfernende Oberfläche mit einem Randabschnitt zum Abstreifen der Fremdkörper.

[0025] Wie in Fig. 5 dargestellt, sind die Fremdkörper entfernenden Schlitze **6** so gebildet, dass jeder eine Neigung (θ2) in Bezug auf die Richtung derr Achse X der Mutter **1** aufweist. Das heißt, dass in einem Fall, in dem die Mittellinie E der Kugelrollnut **9** in einem Steigungswinkel α geneigt ist, in einer vorbestimmten abgelenkten Richtung D in Bezug auf die Richtung (Richtung der Hilfslinie C), die lotrecht zu der Richtung der Achse X der Mutter **1** ist, die Mittellinie des Fremdkörper entfernenden Schlitzes **6** in dem vorbestimmten Winkel (θ2) in der in Bezug auf die Achse X der Mutter **1** der Richtung D entgegengesetzten Richtung geneigt ist. Die Fremdkörper entfernende Abstreiffläche **10b** ist in einem Winkel β von einer Oberfläche aus geneigt, die lotrecht zu der Mittellinie E der Kugelrollnut **9** ist, so dass sie die abgestreiften Fremdkörper in die axiale Richtung X der Mutter verschiebt und diese nach außerhalb der Mutter **1** abführt.

[0026] Wie in Fig. 6 und Fig. 7 dargestellt, ist jedes Dichtungselement **2** mit zwei Nuten **11a** und **11b** an seiner äußeren Umfangsfläche gebildet, die sich beide in der Umfangsrichtung desselben erstrecken. Eine Feder **12a** bzw. **12b** ist um jede der Nuten **11a**, **11b** gewunden. Indem Federn **12a** und **12b** um die äußeren Umfänge der Dichtungselemente **2** herum gewunden werden, wird jedem Dichtungselement **2** eine elastische Eigenschaft verliehen. Das flexible elastische Dichtungselement **2** kann eng an die Spindelwelle angepasst werden, um hierdurch die Dichtungsleistung zu verbessern. Zusätzlich können die Randabschnitte der Schmiermittel zurückhaltenden Abstreiffläche **8b** und der Fremdkörper entfernenden Abstreiffläche **10b** in sicheren Kontakt mit der Spindelwelle gedrängt werden, um hierdurch in verlässlicher Weise das Schmiermittel und die Fremdkörper abzustreifen. Die Anzahl von Nuten, wie **11a** und **11b**, die sich in der Umfangsrichtung jedes Dichtungselements **2** erstrecken, ist nicht auf zwei begrenzt und kann je nach Bedarf gewählt werden. In einem Beispiel ist nur eine einzige Nut an jedem Dichtungselement vorgesehen.

[0027] Die Schmiermittel abstreifende Funktion und die Fremdkörper entfernende Funktion der Dichtungselemente **2** wird nun für den Fall beschrieben, in dem die Spindelwelle in der Richtung F gedreht wird, dargestellt in Fig. 2 und Fig. 4.

[0028] Wenn die Kugelspindel in die Richtung F in Fig. 2 oder Fig. 4 gedreht wird, wird der Randabschnitt der Abstreiffläche **8b** jedes Schmiermittel zurückhaltenden Schlitzes **5** des Dichtungselements **2** in Kontakt mit der äußeren Umfangsfläche der Spindelwelle gleiten. Aus diesem Grund wird das an der äußeren Umfangsfläche der Spindelwelle haftende Schmiermittel von dem Randabschnitt der Abstreiffläche **8b** des Schmiermittel zurückhaltenden Schlitzes **5** abgestreift werden und auf die Abstreiffläche **8b** desselben abgestreift werden. Da diese Abstreiffläche **8b** des Schmiermittel zurückhaltenden Schlitzes in einem Winkel β in Bezug auf die zu der Mittellinie E lotrechten Richtung der Kugelrollnut **9** geneigt ist, wird das Schmiermittel in das Innere der Mutter **1** zurückgeführt. Dementsprechend kann Schmiermittel, das von der Endfläche **2b** des Dichtungselements **2** in den Spalt zwischen der Mutter **1** und der Spindelwelle eindringt, formschlüssig aufgefangen werden und wieder in das Innere der Mutter **1** zurück geführt werden. Zudem kann in dem Fall, in dem die Kugelspindel in die der Richtung F in Fig. 2 oder Fig. 4 entgegengesetzte Richtung gedreht wird, das Schmiermittel an der Endfläche **2b** des Dichtungselements **2** ebenso einbehalten werden wie in dem Fall, in dem ein Schmiermittel entfernender Schlitz nicht ausgebildet ist (siehe Fig. 3).

[0029] In ähnlicher Weise gleitet, wenn die Spindelwelle in die Richtung F in Fig. 2 oder Fig. 4 gedreht wird, der Randabschnitt der Abstreiffläche **10b** des Fremdkörper entfernenden Schlitzes **6** auf der äußeren Umfangsfläche der Spindelwelle in Kontakt mit dieser. Dementsprechend können Fremdkörper, die an der äußeren Umfangsfläche der Spindelwelle haften, abgestreift werden, und die abgestreiften Fremdkörper werden dann zum Entfernen der Fremdkörper auf die Abstreiffläche **10b** gestreift. Zudem werden, da diese Abstreiffläche **10b** eine Neigung β zu einer Richtung hat, die lotrecht zu der Mittellinie E der Kugelrollnut **9** ist, die abgestreiften Fremdkörper aus der Mutter **1** heraus abgeführt.

[0030] Wie vorstehend erläutert wurde, ist in Ausführungen der Erfindung jeder der Schmiermittel zurückhaltenden Abschnitte an dem Dichtungselement von einer in der axialen Richtung der Mutter nach innen weisenden Endfläche des Dichtungselements zu einem Zwischenabschnitt desselben hin ausgebildet. In ähnlicher Weise ist jeder der Fremdkörper entfernenden Abschnitte an dem Dichtungselement von einer in der axialen Richtung der Mutter nach außen weisenden Endfläche des Dichtungselements zu dem Zwischenabschnitt desselben hin ausgebildet. Auf diese Weise kann Schmiermittel, das in den Spalt zwischen dem Dichtungselement und der Spindelwelle durch die Endfläche dringt, formschlüssig aufgefangen werden und in das Innere der Mutter zurück geführt werden, und Fremdkörper, die auf der äußeren Umfangsfläche der Spindelwelle verbleiben, können entfernt und nach außen abgeführt werden. Daher kann das Schmiermittel in dem inneren Abschnitt der Mutter zurückgehalten werden, und es kann verhindert werden, dass die Fremdkörper in das Innere der Mutter eindringen.

Patentansprüche

1. Kugelspindel mit einer Spindelwelle, an der an einer äußeren Umfangsfläche eine Kugelrollnut ausgebildet ist, einer Anzahl von Kugeln, die entlang der Kugelrollnut rollen, einer Mutter (**1**), die mit der Spindelwelle über die Kugeln und Dichtungselemente (**2**), die an beiden Endabschnitten der Mutter angeordnet sind, verschraubt ist, wobei jedes der Dichtungselemente an einer inneren Umfangsfläche mit einem spiralförmigen Vorsprung (**2a**) ausgebildet ist, der in die Kugelrollnut einpassbar ist,
wobei ein Schmiermittel zurückhaltender Abschnitt (**5**) an dem Dichtungselement (**2**) ausgehend von einer in axialer Richtung der Mutter nach innen weisenden Endfläche desselben (**2b**) gebildet ist, und der Schmiermittel zurückhaltende Abschnitt einen Schlitz (**5**) aufweist, und wobei der Schmiermittel zurückhaltende Abschnitt formschlüssig Schmiermittel auffängt, das in den Spalt zwischen dem Dichtungselement und der Spindelwelle durch die Endfläche dringt und das Schmiermittel in das Innere der Mutter (**1**) zurückführt,
und dass der Schlitz (**5**) des Schmiermittel zurückhaltenden Abschnitts sich von der Endfläche (**2b**) des Dichtungselements (**2**) zu einem Zwischenabschnitt desselben erstreckt,
und wobei ein Fremdkörper entfernender Abschnitt (**6**) an dem Dichtungselement gebildet ist, um Fremdkörper, die an einer äußeren Umfangsfläche der Spindelwelle haften, zu entfernen und die Fremdkörper nach außerhalb der Mutter abzuführen,
dadurch gekennzeichnet, dass der die Fremdkörper entfernende Abschnitt ein Schlitz (**6**) ist, der an dem Dichtungselement (**2**) gebildet ist, so dass er sich von einer in axialer Richtung der Mutter nach außen weisenden Endfläche (**2c**) desselben zu einem Zwischenabschnitt desselben erstreckt.

2. Kugelspindel nach Anspruch 1, wobei Presseinrichtungen (**12a**, **12b**) zum Anpressen des Dichtungselements an die Spindelwelle vorgesehen sind.

3. Kugelspindel nach Anspruch 1 oder 2, wobei der Schlitz (**5**) des Schmiermittel zurückhaltenden Abschnitts das Dichtungselement (**2**) von einem inneren Umfangsabschnitt zu einem äußeren Umfangsabschnitt durchdringt.

4. Kugelspindel nach einem der vorhergehenden Ansprüche, wobei der Schlitz (**6**) des Fremdkörper entfernenden Abschnitts das Dichtungselement (**2**) von einem inneren Umfangsabschnitt zu einem äußeren Umfangsabschnitt durchdringt.

5. Kugelspindel nach einem der vorhergehenden Ansprüche, wobei eine Schmiermittel zurückhaltende Abstreiffläche (**8b**) mit einem Randabschnitt zum Abstreifen von Schmiermittel an einer von einander gegenüberliegenden Seitenflächen des Schlitzes (**5**) des Schmiermittel zurückhaltenden Abschnitts gebildet ist und die Schmiermittel zurückhaltende Abstreiffläche (**8b**) so gebildet ist, dass sie eine Neigung (θ1) in eine Drehrichtung der Spindelwelle aufweist und eine Neigung (θ2) in Bezug auf eine Richtung einer Achse der Mutter aufweist, so dass sie das abgestreifte Schmiermittel in axialer Richtung der Mutter verschiebt und das Schmiermittel in die Mutter zurückführt.

6. Kugelspindel nach einem der vorhergehenden Ansprüche, wobei der Schmiermittel zurückhaltende Abschnitt eine Mehrzahl von Schlitzen (**5**) hat und eine der gegenüberliegenden Seitenflächen (**8a**, **8b**) jedes Schlitzes (**5**) als eine Schmiermittel zurückhaltende Abstreiffläche wirkt, die einen Randabschnitt hat, um das Schmiermittel abzustreifen.

7. Kugelspindel nach Anspruch 6, wobei die Schmiermittel zurückhaltenden Schlitze (**5**) so gebildet sind, dass sie jeweils eine Neigung (θ2) relativ zur axialen Richtung der Mutter (**1**) haben.

8. Kugelspindel nach einem der vorhergehenden

Ansprüche, wobei der Fremdkörper entfernende Abschnitt (**6**) eine Mehrzahl von Schlitzen (**6**) hat und eine der einander gegenüberliegenden Oberflächen (**10a**, **10b**) jedes Schlitzes (**6**) als Fremdkörper entfernende Oberfläche wirkt, die einen Randabschnitt hat, um die Fremdkörper abzustreifen.

9. Kugelspindel nach Anspruch 8, wobei die Fremdkörper entfernenden Schlitze (**6**) so gebildet sind, dass sie jeweils eine Neigung (θ2) in Bezug auf die axiale Richtung der Mutter haben.

Beschreibung

Technisches Gebiet

[0001] Die vorliegende Erfindung bezieht sich auf eine schwingungsisolierende dreidimensionale Führungsvorrichtung und insbesondere auf eine schwingungsisolierende dreidimensionale Führungsvorrichtung zur Anordnung zwischen dem Erdboden und einer Struktur um so weit wie möglich zu verhindern, dass die Schwingungen vom Erdboden auf die Struktur (Gebäude) übertragen werden.

Technischer Hintergrund

[0002] Bis jetzt sind einige Strukturen bei einer schwingungsisolierenden Konstruktion eingesetzt worden, die insbesondere dafür ausgelegt wurden, den Effekt von seismischen Schwingungen in Hinsicht der Eigenschaften der seismischen Schwingungen zu minimieren. Eine solche schwingungsisolierte Struktur weist einen Schwingungsisolator auf, der zwischen dem Erdboden und der Struktur angeordnet ist, um soweit wie möglich zu verhindern, dass Schwingungen vom Erdboden aufgrund von Erdbeben auf die Struktur (Gebäude) übertragen werden.

[0003] Gemäß einem solchen Schwingungsisolator, wie er in den Fig. 15A und Fig. 15B der beigefügten Zeichnungen gezeigt ist (Fig. 15A ist eine Ansicht und Fig. 15B ist eine Draufsicht), ist ein Gebäude **301** nicht an einem Fundament **302** befestigt, sondern eine Vielzahl von Führungsvorrichtungen **303**, um zu gestatten, dass das Gebäude **301** sich auf dem Fundament **302** bewegt, ist zwischen dem Fundament **302** und dem Gebäude **301** angeordnet. Wenn höhere seismische Kräfte als ein gewisses Niveau aufgebracht werden, gleitet das Gebäude **301** auf den Führungsvorrichtungen **303**, um zu verhindern, dass die seismischen Kräfte auf das Gebäude **301** wirken.

[0004] Die Anmelderin der vorliegenden Erfindung hat zuvor dreidimensionale Führungsvorrichtungen zur Anwendung als die obige Führungsvorrichtung in der japanischen Patentanmeldung Nr. 9-37072 vorgeschlagen, die als JP-A-09-324 555 nach dem Prioritätsdatum der vorliegenden Anmeldung veröffentlicht wurde. Die vorgeschlagenen dreidimensionalen Führungsvorrichtungen sind grob in zwei Bauarten gruppiert. Fig. 12 der beigefügten Zeichnungen zeigt die Perspektive von einer der Bauarten der vorgeschlagenen dreidimensionalen Führungsvorrichtung. Wie in Fig. 12 gezeigt, hat die dreidimensionale Führungsvorrichtung eine Basis **140**, eine erste gekrümmte Führungsvorrichtung **150**, die an der Basis **140** montiert ist und eine bogenförmige Spur bzw. Schiene besitzt, eine zweite gekrümmte Führungsvorrichtung **116**, die über der ersten gekrümmten Führungsvorrichtung **150** angeordnet ist und eine Bewegungsebene entlang einer bogenförmigen Spur bzw. Schiene besitzt, die die Bewegungsebene der ersten gekrümmten Führungsvorrichtung **150** kreuzt, und ein Zwischenglied **170**, welches zwischen der ersten gekrümmten Führungsvorrichtung **150** und der zweiten gekrümmten Führungsvorrichtung **160** positioniert ist und die erste gekrümmte Führungsvorrichtung **150** und die zweite gekrümmte Führungsvorrichtung **160** verbindet.

[0005] Die ersten und zweiten gekrümmten Führungsvorrichtungen **150**, **160** weisen Führungsschienen **151**, **161** auf, die vertikal mit einer vorbestimmten Krümmung gekrümmt sind und Kugellaufnuten **153**, **163** besitzen, die entlang einer Bogenform von vorbestimmter Krümmung in gegenseitig gegenüberstehenden Oberflächen definiert sind, weiter Lagerblöcke **152**, **162**, die einen U-förmigen Querschnitt über die Führungsschienen **151**, **161** aufweisen, und die Kugellaufnuten besitzen, die in Ausrichtung mit den Kugellaufnuten in den Raupenschienen **151**, **161** definiert sind, und zwar entlang einer Bogenform von vorbestimmter Krümmung, und eine Vielzahl von (nicht gezeigten) Kugeln, die zum Tragen von Lasten zwischen den Kugellaufnuten in den Führungsschienen **151**, **161** und den Kugellaufnuten in den Tragblöcken bzw. Lagerblöcken **152**, **162** angeordnet sind. Das Zwischenglied **170**, wel ches die erste gekrümmte Führungsvorrichtung **150** und die zweite gekrümmte Führungsvorrichtung **160** verbindet, ist in Form eines starren Blockes.

[0006] Fig. 13 der beigefügten Zeichnungen ist eine Ansicht, die die Weise zeigt, in der die dreidimensionale Führungsvorrichtung verwendet wird, die in Fig. 12 gezeigt ist.

[0007] Wie in Fig. 13 gezeigt, haben dreidimensionale Führungsvorrichtungen **303** jeweilige sphärische bzw. kugelförmige Führungsschienen, deren Krümmungsmittelpunkte getrennt an einem Gebäude **301** eingerichtet sind und nicht als eine gemeinsame Mitte. Zwischen dem Gebäude **301** und den dreidimensionalen Führungsvorrichtungen sind Kippaufnahmemechanismen **304** vorgesehen, um zu gestatten, dass die Kippbewegungen absorbiert werden, die zwischen dem Gebäude **301** und den dreidimensionalen Führungsvorrichtungen **303** erzeugt werden, wenn Schwingungen auftreten. Jeder der Kippaufnahmemechanismen **304** kann eine Universalverwendung aufweisen, ein Kugellager oder ein elastisches Glied aus Gummi oder ähnlichem.

[0008] Fig. 14 der beigefügten Zeichnungen ist eine Frontansicht, die eine andere Bauart einer zuvor vorgeschlagenen dreidimensionalen Führungsvorrichtung zeigt.

[0009] Wie in Fig. 14 gezeigt, weist die dreidimensionale Führungsvorrichtung eine Basis **140** auf, weiter eine erste gekrümmte Führungsvorrichtung **150**, die an der Basis **140** montiert ist und eine bogenförmige Spur bzw. Führung besitzt, eine zweite gekrümmte Führungsvorrichtung **160**, die um die erste gekrümmte Führungsvorrichtung **150** herum angeordnet ist und eine Bewegungsebene entlang einer bogenförmigen Führung besitzt, die die Bewegungsebene der ersten gekrümmten Führungsvorrichtung **150** kreuzt, und ein Zwischenglied **170**, welches zwischen der ersten gekrümmten Führungsvorrichtung **150** und der zweiten gekrümmten Führungsvorrichtung **160** positioniert ist und die erste gekrümmte Führungsvorrichtung **150** und die zweite gekrümmte Führungsvorrichtung **160** miteinander verbindet. Eine sich bewegende Basis **180**, auf der ein Gebäude getragen wird, ist fest an der zweiten gekrümmten Führungsvorrichtung **160** montiert. In diesem Beispiel weist das Zwischenglied **170** eine Universalverbindung auf, um Kippvorgänge zwischen der ersten gekrümmten Führungsvorrichtung **150** und der zweiten gekrümmten Führungsvorrichtung **160** aufzunehmen. Das Zwischenglied kann anstelle der Universalverbindung ein Kugellager oder ein elastisches Glied aufweisen, wie beispielsweise eine Feder oder ein Gummiglied.

[0010] Die ersten und zweiten gekrümmten Führungsvorrichtungen **150**, **160** weisen Führungsschienen bzw. Spurschienen **151**, **161** auf, die vertikal mit einer vorbestimmten Krümmung gekrümmt sind und Kugellaufnuten **153**, **163** besitzen, die entlang einer Bogenform von vorbestimmter Krümmung in gegenseitig gegenüberstehenden Oberflächen definiert sind, weiter Lagerblöcke **152**, **162**, die einen U-förmigen Querschnitt über den Spurschienen **151**, **161** besitzen, und die Kugellaufnuten besitzen, die in Ausrichtung mit den Kugellaufnuten in den Spurschienen **151**, **161** entlang einer Bogenform von vorbestimmter Krümmung definiert sind, und eine Vielzahl von (nicht gezeigten) Kugeln, die zum Tragen von Lasten zwischen den Kugellaufnuten in den Führungsschienen bzw. Spurschienen **151**, **161** und den Kugellaufnuten in den Lagerblöcken **152**, **162** angeordnet sind.

[0011] In Abwesenheit von seismischen Schwingungen gestattet die schwingungsisolierende Konstruktion mit der obigen dreidimensionalen Führungsvorrichtung, dass das Gebäude stabil in einer stetigen Position auf der dreidimensionalen Führungsvorrichtung positioniert ist. Auch wenn ein Erdbeben auftritt und bewirkt, dass der Erdboden schwingt, sind der Boden und das Gebäude gegen die Übertragung von Schwingungen durch die dreidimensionale Führungsvorrichtung isoliert, so dass große Schwingungen nicht auf das Gebäude übertragen werden. Nachdem seismische Schwingungen abgeklungen sind, werden irgendwelche Schwingungen des Gebäudes mit Bezug zum Erdboden gedämpft, und das Gebäude wird in der stetigen Position auf der dreidimensionalen Führungsvorrichtung stabilisiert.

[0012] Damit die dreidimensionale Führungsvorrichtung, die in der japanischen Patentanmeldung Nr. 9-37072 vorgeschlagen wird, das Gebäude in einem horizontalen Zustand hält, wenn das Gebäude unter Schwingungen leidet, die durch Erdbeben oder ähnliches verursacht werden, ist es nötig, einen Kippabsorptionsmechanismus zwischen der ersten gekrümmten Führungsvorrichtung und der zweiten gekrümmten Führungsvorrichtung vorzusehen. Der Kippabsorptionsmechanismus weist eine Universalverbindung, ein Kugellager oder ein elastisches Glied auf, wie beispielsweise eine Feder oder ein Gummiglied.

[0013] Wenn der Kippabsorptionsmechanismus eine Universalverbindung bzw. Kreuzgelenk oder ein Kugellager aufweist, werden Spannungen, die auf dem gleitenden Teil entwickelt werden, übermäßig größer als jene, die in anderen Gliedern entwickelt werden, da das Gesamtgewicht des Gebäudes auf einem gleitenden Teil getragen werden muß, wie beispielsweise auf einer Kreuzgelenkwelle (Universalverbindung) oder einem Kugelsitz mit einer kleinen Fläche, und diese tendieren dazu, in kurzer Zeit zu zerbrechen oder abgenutzt zu werden.

[0014] Wenn der Kippabsorptionsmechanismus ein elastisches Glied aufweist, wie beispielsweise ein Gummiglied, siehe JP-A-09-72333, dann kann er nur Lasten innerhalb eines elastisch verformbaren Bereiches tragen und kann nicht höhere Lasten tragen. Ein weiteres Problem ist, dass das elastische Glied eine schlechte Haltbarkeit hat, da es aufgrund von Alterung wahrscheinlich an Setzung leidet. Das heißt, die in der japanischen Patentanmeldung Nr. 9-37072 oder in JP-A-09-72333 vorgeschlagene Vorrichtung kann wegen dem Kippabsorptionsmechanismus keine schweren Lasten tragen.

[0015] Es ist ein Ziel der vorliegenden Erfindung, eine dreidimensionale Führungsvorrichtung vorzusehen, die eine Kippabsorptionsfunktion hat, die schwere Lasten tragen kann, und die eine hervorragende Haltbarkeit hat.

Offenbarung der Erfindung

[0016] Um das obige Ziel zu erreichen, ist gemäß der vorliegenden Erfindung eine dreidimensionale Führungsvorrichtung mit einer Basis vorgesehen, weiter mit einer ersten gekrümmten Führungsvorrichtung, die an der Basis montiert ist und eine bogenförmige Spur bzw. Führung besitzt, weiter eine zweite gekrümmte Führungsvorrichtung, die um die erste gekrümmte Führungsvorrichtung herum angeordnet ist und eine Bewegungsebene entlang einer bogenförmigen Spur besitzt, die die Bewegungsebene der ersten gekrümmten Führungsvorrichtung überkreuzt, und ein Zwischenglied, welches zwischen der ersten gekrümmten Führungsvorrichtung und der zweiten gekrümmten Führungsvorrichtung positioniert ist und die erste gekrümmte Führungsvorrichtung und die zweite gekrümmte Führungsvorrichtung verbindet, wobei jede der ersten und zweiten gekrümmten Führungsvorrichtungen folgendes aufweist: eine Führungsschiene bzw. Spurschiene, die vertikal mit einer vorbestimmten Krümmung gekrümmt ist und eine Vielzahl von Wälzelementlaufnuten besitzt, die in den Außenflächen davon definiert sind; weiter einen Lagerblock, der einen im Wesentlichen zylindrischen starren Körper besitzt und in den Innenflächen davon eine Vielzahl von Wälzelementlaufnuten in Ausrichtung mit den Wälzelementlaufnuten in der Spurschiene besitzt, und nicht belastete Wälzelementrolldurchlässe benachbart zu den Wälzelementlaufnuten; weiter ein Paar von Deckeln, die jeweils auf den vorderen und hinteren Enden der Lagerblöcke montiert sind und jeweilige Wälzelementrichtungsänderungsdurchlässe besitzen, die in jeweiligen Innenflächen davon definiert sind, wobei die Wälzelementrichtungsänderungsdurchlässe Enden der Wälzelementlaufnuten und der nicht belastenden Wälzelementdurchlässe verbinden, und einen endlosen Zirkulationspfad für Wälzelemente vorsehen; und eine Vielzahl von Wälzelementen, die angeordnet sind, um in dem endlosen Wälzelementzirkulationspfad zu zirkulieren, um Lasten zwischen den Wälzelementlaufnuten in der Spurschiene und den Wälzelementlaufnuten in dem Lagerblock zu tragen; wobei das Zwischenglied einen starren Körper in Form eines Blocks besitzt, und offene zylindrische Ausnehmungen besitzt, die jeweils in zwei Oberflächen davon definiert sind, wobei die Lagerblöcke drehbar in die offenen zylindrischen Ausnehmungen gepaßt sind.

[0017] Das Zwischenglied weist einen starren Körper in Form eines Blocks und des Lagerblocks auf; wobei jeder einen starren Körper aufweist, und wobei die ersten und zweiten gekrümmten Führungsvorrichtungen drehbar jeweils in den zylindrischen Ausnehmungen eingepasst sind, die jeweils in den zwei Oberflächen des Zwischengliedes definiert sind, was somit eine Kippabsorptionsfähigkeit zwischen den ersten und zweiten Führungsvorrichtungen vorsieht. Da die Kippabsorptionsmöglichkeit ausgeführt wird und das Gebäude durch gleitende Oberflächen getragen wird, die eine große Kontaktfläche haben, und die durch die berührenden starren Körper vorgesehen werden, kann die dreidimensionale Führungsvorrichtung schwerere Lasten tragen und eine hervorragende Haltbarkeit aufweisen.

Bester Weg zur Ausführung der Erfindung

[0033] Ausführungsbeispiele der dreidimensionalen Führungsvorrichtung gemäß der vorliegenden Erfindung werden im Detail unten mit Bezug auf die Fig. 1

bis Fig. 13 beschrieben.

[Erstes Ausführungsbeispiel]

[0034] Die Fig. 1 bis Fig. 4 zeigen eine dreidimensionale Führungsvorrichtung gemäß einem ersten Ausführungsbeispiel der vorliegenden Erfindung. Fig. 1 ist eine Perspektivansicht der dreidimensionalen Führungsvorrichtung, **Fig.** 2 ist eine Perspektivansicht der ersten und zweiten gekrümmten Führungsvorrichtung, Fig. 3 ist eine Perspektivansicht, die einen Lagerblock zeigt, und Fig. 4 ist eine Perspektivansicht, die ein Zwischenglied zeigt.

[0035] Wie in Fig. 1 gezeigt, weist die dreidimensionale Führungsanordnung gemäß dem ersten Ausführungsbeispiel eine Basis **23** auf, die an einem Fundament befestigt ist, weiter eine erste gekrümmte Führungsvorrichtung **21**, die an der Basis **23** montiert ist und eine bogenförmige Spur bzw. Schiene besitzt, weiter eine zweite gekrümmte Führungsvorrichtung **22**, die über der ersten gekrümmten Führungsvorrichtung **21** angeordnet ist und eine Bewegungsebene entlang einer bogenförmigen Spur besitzt, die die Bewegungsebene der ersten gekrümmten Führungsvorrichtung **21** kreuzt, und ein Zwischenglied **24**, welches zwischen der ersten gekrümmten Führungsvorrichtung **21** und der zweiten gekrümmten Führungsvorrichtung **22** positioniert ist und die erste gekrümmte Führungsvorrichtung **21** und die zweite gekrümmte Führungsvorrichtung **22** verbindet. Eine sich bewegende Basis **25**, auf der ein Gebäude getragen wird, ist fest an der zweiten gekrümmten Führungsvorrichtung **22** montiert.

[0036] Die erste gekrümmte Führungsvorrichtung **21** und die zweite gekrümmte Führungsvorrichtung **22** sind strukturell miteinander identisch. Wie in den Fig. 2A und Fig. 2B gezeigt (Fig. 2A ist eine bruchstückhafte Perspektivansicht, die teilweise aufgebrochen ist, und Fig. 2B ist eine querverlaufende Querschnittsansicht) weisen sowohl die erste gekrümmte Führungsvorrichtung **21** als auch die zweite gekrümmte Führungsvorrichtung **22** eine gekrümmte Spurschiene **1** auf, die vertikal mit einer vorbestimmten Krümmung gekrümmt ist, und einen Tragblock bzw. Lagerblock **10**, der verschiebbar auf der gekrümmten Spurschiene **1** durch eine Anzahl von Kugeln **9** getragen wird, und der einen endlosen Kugelzirkulationsdurchlaß besitzt. Wie in Fig. 1 gezeigt, hat die gekrümmte Spurschiene **1** eine im Wesentlichen rechteckige Querschnittsform und ist bogenförmig mit einer vorbestimmten vertikalen Krümmung gekrümmt. Die gekrümmte Spurschiene **1** hat einen Krümmungsmittelpunkt O, der vertikal oben positioniert ist, und einen Krümmungsradius R. Die gekrümmte Spurschiene **1** hat eine konvexe Befestigungsoberfläche (Unterseite) **1a** und eine konkave Oberfläche (Oberseite) **1b** gegenüberliegend zur Befestigungsoberfläche **1a**.

[0037] Die Befestigungsfläche (Unterseite) der Spurschiene **1** wird als eine erste Oberfläche **1** bezeichnet, die Oberfläche (Oberseite) gegenüberliegend zur Befestigungsfläche als eine zweite Oberfläche **1b**, und beide Seitenflächen, die sich von beiden Oberflächen der ersten Oberfläche **1a** erstrecken, werden als dritte und vierte Oberflächen **1c**, **1d** bezeichnet.

[0038] Wie in den Fig. 2A und Fig. 2B gezeigt, haben die dritten und vierten Oberflächen **1c**, **1d** der gekrümmten Spurschiene **1** Kugellaufnuten **111**, die dadurch entlang einer Bogenform von vorbestimmter Krümmung definiert sind, und die zweite Oberfläche **1b** hat parallele Kugellaufnuten **112** entlang der Spurschiene **1**.

[0039] Der Tragblock bzw. Lagerblock **10** weist einen im wesentlichen zylindrischen starren Körper auf und hat einen nach unten weisenden offenen Hohlraum **101** darin definiert. Der Lagerblock **10** hat auch Kugellaufnuten **221**, die in beiden Innenseitenflächen **10c**, **10d** davon in Ausrichtung mit den Kugellaufnuten **111** in der gekrümmten Spurschiene **1** entlang einer Bogenform von vorbestimmter Krümmung definiert sind (mit dem Krümmungsradius R). Der Lagerblock **10** hat auch parallele Kugellaufnuten **222**, die in einer unteren Innenseite **10a** davon in Ausrichtung mit den Kugellaufnuten **112** definiert sind.

[0040] Der Lagerblock **10** hat auch nicht belastete Kugeldurchlässe **223**, **224** benachbart darin zu den Kugellaufnuten **221**, **222** definiert, und zwar in Assoziation mit den Kugellaufnuten **221**, **222**. Wie in den Fig. 2A und Fig. 2B gezeigt, sind Deckel **13**, **13** jeweils an vorderen und hinteren Enden des Lagerblockes **10** montiert und haben jeweilige Kugelrichtungsumlenkdurchlässe bzw. Kugelrücklaufdurchlässe **15**, die in jeweiligen Innenflächen davon definiert sind, und die Enden der Kugellaufnuten **221**, **222** und der nicht belasteten Kugeldurchlässe **223**, **224** verbinden, was somit einen endlosen Kugelzirkulationspfad vorsieht. Die Kugeln **9** sind angeordnet, um in dem endlosen Kugelumlaufpfad zu zirkulieren, um Lasten zwischen den Kugellaufnuten **111**, **112** in der Spurschiene **1** und den Kugellaufnuten **221**, **222** in dem Lagerblock **10** zu tragen.

[0041] Kontaktwinkellinien, die Kontaktpunkte zwischen den Kugeln **9** und den gegenüberstehenden unteren Kugellaufnuten **111**, **221** verbinden, sind in horizontaler Richtung um 45 Grad geneigt. Kontaktlinien, die Kontaktpunkte zwischen den Kugeln **9** und den gegenüberstehenden oberen Kugellaufnuten **112**, **222** verbinden, erstrecken sich in vertikaler Richtung (der Richtung, in welcher Lasten aufgebracht sind).

[0042] Fig. 3 ist eine Perspektivansicht, die die oberen und unteren Kugellaufnuten **221**, **222** zeigt, die in dem inneren Hohlraum in dem Lagerblock **10** definiert sind. Die oberen und unteren Kugellaufnuten **221**, **222** haben eine Bogenform mit einer vorbestimmten vertikalen Krümmung (Krümmungsradius R) und sind nach unten konvex.

[0043] Fig. 4 ist eine Perspektivansicht des Zwischengliedes **24** in Form eines Blockes. Wie in Fig. 4 gezeigt, weist das Zwischenglied **24** einen starren Körper auf, im Wesentlichen in Form eines rechteckigen Parallelepipedes, und es hat eine obere zylindrische Ausnehmung **241**, **242**, die jeweils in der Ober- und Unterseite **24a**, **24b** definiert sind. Die Lagerblöcke **10** sind drehbar jeweils in den zylindrischen Ausnehmungen **241**, **242** eingepaßt. Die Lagerblöcke **10**, die jeweils in die zylindrischen Ausnehmungen **241**, **242** eingepasst sind, sind durch Befestigungsmittel festgelegt, so dass die Lagerblöcke **10** um die Längsachsen davon mit Bezug auf das Zwischenglied **24** drehbar sind, jedoch entlang der Längsachsen davon unbeweglich sind.

[0044] Gemäß dem ersten Ausführungsbeispiel weist das Zwischenglied **24** einen starren Körper in Form eines Blockes auf, und die Lagerblöcke **10**, **10** der ersten und zweiten Führungsvorrichtung **21**, **22**, die jeweils einen starren Körper aufweisen, sind drehbar jeweils in die zylindrischen Ausnehmungen **241**, **242** eingepasst, die jeweils in den Ober- und Unterseiten des Zwischengliedes **24** definiert sind, was somit eine Möglichkeit zur Aufnahme einer Verkippung zwischen den ersten und zweiten gekrümmten Führungsvorrichtungen **21**, **22** vorsieht. Da die Möglichkeit zur Aufnahme einer Verkippung ausgeführt ist und das Gebäude durch gleitende Oberflächen getragen wird, die eine große Kontaktfläche haben, und die in den sich berührenden starren Körpern vorgesehen sind (die Innenumfangsflächen der Ausnehmungen **241**, **242** des Zwischengliedes **24** und der Außenumfangsflächen der Lagerblöcke **10**), kann die dreidimensionale Führungsvorrichtung schwere Lasten tragen und eine hervorragende Haltbarkeit aufweisen.

[0045] Wenn das Fundament des Gebäudes auf der sich bewegenden Basis **25** aufgrund eines Erdbebens schwingt, welches durch Erdkrustenbewegungen verursacht wird, bewegt sich in dem ersten Ausführungsbeispiel das Gebäude entlang der oberen und unteren gekrümmten Spurschienen **1** aufgrund der Beschleunigung. Dies kommt daher, dass die Beschleunigung in Komponenten entlang der X-und Y-Richtungen der Spurschienen **1** durch die seismische Schwenkbewegung in irgendeiner willkürlichen Richtung aufgeteilt ist. Auch wenn das Gebäude schwingt, wird die Aufnahmefähigkeit für Verkippungen durch die Winkelbewegung zwischen dem Zwischenglied **24** und den Lagerblöcken **10** ausgeführt, um somit das Gebäude horizontal zu halten. Da die oberen und unteren gekrümmten Spurschienen **1** in gegenseitig senkrechten Richtungen zu jedem Zeitpunkt gehalten werden, kann eine Vielzahl von dreidimensionalen Führungsvorrichtungen leicht richtungsmäßig ausgerichtet werden, wenn das Gebäude aufgebaut wird. Insbesondere sobald die gekrümmten Spurschienen **1** der Fundamentseite richtungsmäßig ausgerichtet sind, sind die gekrümmten Spurschienen **1** der Gebäudeseite notwendigerweise festgelegt und müssen nicht richtungsmäßig ausgerichtet werden.

[0046] In dem ersten Ausführungsbeispiel ist weiterhin eine Vielzahl von dreidimensionalen Führungsvorrichtungen zwischen dem Erdboden und dem Gebäude angeordnet. Insofern als die oberen und unteren Lagerblöcke **10** mit Bezug auf das Zwischenglied **24** drehbar sind, können irgendwelche Fehlausrichtungen (Zentrierungsfehler) und Niveaufehler leicht aufgenommen werden. Das Zwischenglied **24** in Form eines einfachen Blockes mit niedrigem Profil gestattet, dass die dreidimensionale Führungsvorrichtung in vertikaler Höhe kleiner ist als sie es sein würde, wenn eine Universalverbindung bzw. ein Kreuzgelenk als das Zwischenglied verwendet werden würde.

[Zweites Ausführungsbeispiel]

[0047] Die Fig. 5 bis Fig. 7 zeigen eine dreidimensionale Führungsvorrichtung gemäß einem zweiten Ausführungsbeispiel der vorliegenden Erfindung. Fig. 5 ist eine Seitenansicht der dreidimensionalen Führungsvorrichtung, Fig. 6 ist eine Querschnittsansicht, die entlang der Linie VI-VI der Fig. 5 aufgenommen ist, und Fig. 7 ist eine vergrößerte bruchstückhafte Ansicht eines Teils der Fig. 5. Jene Teile des in den Fig. 5 bis Fig. 7 gezeigten Ausführungsbeispiels, die in derselben Weise arbeiten, wie jene des in den Fig. 1 bis Fig. 4 gezeigten Ausführungsbeispiels, werden mit identischen Bezugszeichen beschrieben.

[0048] Die Hauptanordnung des zweiten Ausführungsbeispiels ist identisch mit der Anordnung des ersten Ausführungsbeispiels. Jedoch sind eine zweite gekrümmte Führungsvorrichtung **22** und ein Zwischenglied **24** gemäß dem zweiten Ausführungsbeispiel anders als jene des ersten Ausführungsbeispiels. Insbesondere wie in den Fig. 5 und Fig. 6 gezeigt, hat die gekrümmte Spurschiene **1** der zweiten gekrümmten Führungsvorrichtung **22** der dreidimensionalen Führungsvorrichtung gemäß dem zweiten Ausführungsbeispiel eine im Wesentlichen rechteckige Querschnittsform und ist bogenförmig mit einer vorbestimmten vertikalen Krümmung gekrümmt, wie bei dem ersten Ausführungsbeispiel, ist jedoch um 90 Grad gegenüber der gekrümmten Spurschiene **1** gemäß dem ersten Ausführungsbeispiel versetzt. Die gekrümmte Spurschiene **1** der zweiten gekrümmten Führungsvorrichtung **22** hat eine konkave dritte

Oberfläche **1c** und eine konvexe vierte Oberfläche **1d**. Wie in Fig. 7 gezeigt, haben die dritten und vierten Oberflächen **1c**, **1d** der Spurschiene **1** jeweilige Kugellaufnuten **111** darin entlang der Spurschiene **1** definiert. Die zweite Oberfläche **1b** gegenüberliegend zur ersten Oberfläche **1a** hat parallele Kugellaufnuten **112**, die darin entlang einer Bogenform von vorbestimmter Krümmung definiert sind.

[0049] Der Lagerblock **10** der zweiten gekrümmten Führungsvorrichtung **22** weist einen im Wesentlichen zylindrischen starren Körper auf und hat Innenseitenflächen **10c**, **10d**, die gekrümmte Oberflächen entlang der dritten und vierten Oberflächen **1c**, **1d** der Spurschiene **1** aufweisen. Die dritten und vierten Oberflächen **10c** und **10d** des Lagerblockes **10** haben darin definierte Kugellaufnuten **221** in Ausrichtung mit den Kugellaufnuten **111** der gekrümmten Spurschiene **1**. Der Lagerblock **10** hat auch parallele Kugellaufnuten **222**, die in seiner unteren Innenfläche **10a** definiert sind, und zwar in Ausrichtung mit den Kugellaufnuten **112** entlang einer Bogenform von vorbestimmter Krümmung.

[0050] Das Zwischenglied **24** hat eine offene zylindrische Ausnehmung **242**, die in einer Unterseite **24b** davon definiert ist, und eine offene zylindrische Ausnehmung **241**, die in einer Seitenfläche **24c** davon definiert ist. Lagerblöcke **10** sind drehbar jeweils in die zylindrischen Ausnehmungen **241**, **242** eingepasst. Eine sich bewegende Basis **25** ist fest an der ersten Oberfläche **1a** (Befestigungsfläche) der Spurschiene **1** befestigt und erstreckt sich nach oben. Die Oberseite der sich bewegenden Basis **25** bildet eine Einbau- bzw. Befestigungsfläche für das Gebäude. Die Teile der anderen Komponenten, wie beispielsweise die erste gekrümmte Führungsvorrichtung **21**, sind identisch mit jenen des ersten Ausführungsbeispiels.

[Drittes Ausführungsbeispiel]

[0051] Die Fig. 8 bis Fig. 10 zeigen eine dreidimensionale Führungsvorrichtung gemäß einem dritten Ausführungsbeispiel der vorliegenden Erfindung. Fig. 8 ist eine Seitenansicht der dreidimensionalen Führungsvorrichtung, und Fig. 9 ist eine Querschnittsansicht, die entlang der Linie IX-IX der Fig. 8 aufgenommen ist. Jene Teile des in den Fig. 8 bis Fig. 10 gezeigten Ausführungsbeispiels, die in der gleichen Weise arbeiten, wie jene des in den Fig. 1 bis Fig. 4 gezeigten Ausführungsbeispiels, werden mit identischen Bezugszeichen beschrieben.

[0052] Die Hauptanordnung des dritten Ausführungsbeispiels ist identisch mit der Anordnung des zweiten Ausführungsbeispiels. Jedoch sind eine erste gekrümmte Führungsvorrichtung **21** und ein Zwischenglied **24** gemäß dem dritten Ausführungsbeispiel anders als jene des zweiten Ausführungsbeispiels. Insbesondere wie in den Fig. 8 und Fig. 9 gezeigt, hat die gekrümmte Spurschiene **1** der ersten gekrümmten Führungsvorrichtung **21** der dreidimensionalen Führungsvorrichtung gemäß dem dritten Ausführungsbeispiel eine im wesentlichen rechteckige Querschnittsform und ist bogenförmig mit einer vorbestimmten vertikalen Krümmung gekrümmt, wie bei dem zweiten Ausführungsbeispiel, ist jedoch in Winkelrichtung um 90 Grad gegenüber der gekrümmten Spurschiene **1** gemäß dem zweiten Ausführungsbeispiel verschoben. Die gekrümmte Spurschiene **1** der zweiten gekrümmten Führungsvorrichtung **22** hat eine konkave dritte Oberfläche **1c** und eine konvexe vierte Oberfläche **1d**. Wie in Fig. 10 gezeigt, haben die dritten und vierten Oberflächen **1c**, **1d** der Spurschiene **1** jeweilige Kugellaufnuten **111**, die darin entlang der Spurschiene **1** definiert sind. Die zweite Oberfläche **1b** hat parallele Kugellaufnuten **112**, die darin entlang einer Bogenform von vorbestimmter Krümmung definiert sind.

[0053] Der Lagerblock **10** der ersten gekrümmten Führungsvorrichtung **21** weist einen im Wesentlichen zylindrischen starren Körper auf und hat Innenseitenflächen **10c**, **10d**, die gekrümmte Oberflächen entlang der dritten und vierten Oberflächen **1c**, **1d** der Spurschiene **1** aufweisen. Die dritten und vierten Oberflächen **10c**, **10d** des Lagerblockes **10** haben Kugellaufnuten **221**, die darin in Ausrichtung mit den Kugellaufnuten **111** der gekrümmten Spurschiene **1** definiert sind. Der Lagerblock **10** hat auch parallele Kugellaufnuten **222**, die in einer unteren Innenseite **10a** davon in Ausrichtung mit den Kugellaufnuten **112** entlang einer Bogenform von vorbestimmter Krümmung definiert sind.

[0054] Das Zwischenglied **24** hat eine offene zylindrische Ausnehmung **241**, die in einer Seitenfläche **24c** davon definiert ist, und eine offene zylindrische Ausnehmung **242**, die in einer anderen Seitenfläche **24d** davon definiert ist. Die Lagerblöcke **10** sind drehbar jeweils in die zylindrischen Ausnehmungen **241**, **242** eingepasst. Eine Basis **23** ist fest an der ersten Oberfläche (Befestigungsfläche) **1a** der Spurschiene **1** befestigt und erstreckt sich nach unten. Die Teile von anderen Komponenten, wie beispielsweise die zweite gekrümmte Führungsvorrichtung **22**, sind identisch mit jenen des zweiten Ausführungsbeispiels. Gemäß den zweiten und dritten Ausführungsbeispielen sind die Lagerblöcke **10**, die in die Seiten des Zwischenblockes **24** eingepasst sind, dahingehend wirksam, dass sie die gesamte vertikale Höhe der dreidimensionalen Führungsvorrichtung verringern.

[Viertes Ausführungsbeispiel]

[0055] Fig. 11 zeigt eine dreidimensionale Führungsvorrichtung gemäß einem vierten Ausführungsbeispiel der vorliegenden Erfindung. Gemäß dem vierten Ausführungsbeispiel sind der Mittelteil des Lagerblockes **10** der ersten gekrümmten Führungsvorrichtung **21** und der Mittelteil des Lagerblockes **10** der zweiten gekrümmten Führungsvorrichtung **22** in einer Ebene angeordnet, um die zwei senkrechten Spurschienen **1** nahe zusammen zu einer Position gerade kurz vor einer physischen Gegenwirkung miteinander zu bringen.

[0056] Die Anordnung der ersten und zweiten gekrümmten Führungsvorrichtung **21**, **22** in dem in Fig. 11 gezeigten Ausführungsbeispiel ist identisch mit der Anordnung von jenen gemäß dem zweiten Ausführungsbeispiel, welches in den Fig. 5 bis Fig. 7 gezeigt ist. Ein Zwischenglied **24** weist zwei Blöcke **24A**, **24B** auf, jeweils in Form eines rechteckigen Parallelepipedes, die miteinander durch einen L-förmigen Verbinder **24C** verbunden sind. Das Zwischenglied **24** hat zylindrische Ausnehmungen **241**, **242**, die jeweils in einer Seitenfläche **24c** und einer Unterseite **24b** definiert sind, wobei die Lagerblöcke **10** in die zylindrischen Ausnehmungen **241**, **242** eingepasst sind. Das Zwischenglied **24** insgesamt hat ein niedrigeres Profil als das Zwischenglied gemäß dem zweiten Ausführungsbeispiel. Das Zwischenglied **24** ist nicht in einem Bereich vorhanden, wo die zwei Spurschienen **1** einander überkreuzen. Daher können zwei Spurschienen **1** nahe zusammen zu einer Position gerade kurz vor einer physischen Gegenwirkung miteinander gebracht werden.

[0057] Gemäß dem vierten Ausführungsbeispiel wird die gesamte vertikale Höhe der dreidimensionalen Führungsvorrichtung verringert, weil das Zwischenglied **24** so geformt ist, dass es die zwei Spurschienen **1** zusammen zu einer Position gerade kurz vor einer physischen Gegenwirkung miteinander bringt.

[0058] Bei den obigen Ausführungsbeispielen sind Kugeln als Wälzelemente beschrieben worden, jedoch können Rollen als Wälzelemente eingesetzt werden.

[0059] Gemäß der vorliegenden Erfindung, wie sie oben beschrieben wurde, weist das Zwischenglied einen starren Körper in Form eines Blockes auf, und die Lagerblöcke, jeweils in Form eines starren Körpers, der ersten und zweiten gekrümmten Führungsvorrichtung sind drehbar in die jeweiligen zwei Oberflächen des Zwischengliedes eingepasst, um dadurch eine Aufnahmefähigkeit für eine Verkippung zwischen den ersten und zweiten gekrümmten Führungsvorrichtungen vorzusehen. Da die Aufnahmefähigkeit für Verkippungen ausgeführt ist und das Gebäude durch gleitende Flächen getragen wird, die eine große Kontaktfläche haben, und die in den sich berührenden starren Körpern vorgesehen sind, kann daher die dreidimensionale Führungsvorrichtung schwere Lasten tragen und eine hervorragende Haltbarkeit aufweisen.

[0060] Gemäß der vorliegenden Erfindung sind weiterhin eine Vielzahl von dreidimensionalen Führungsvorrichtungen zwischen dem Erdboden und dem Gebäude angeordnet. Insofern als die zwei Lagerblöcke mit Bezug zu dem Zwischenglied drehbar sind, können irgendwelche Fehlausrichtungen (Zentrierungsfehler) und Niveaufehler leicht aufgenommen werden. Das Zwischenglied in Form eines einfachen Blockes mit niedrigem Profil gestattet, dass die dreidimensionale Führungsvorrichtung in vertikaler Höhe kleiner ist als sie es wäre, wenn eine Universalverbindung bzw. ein Kreuzgelenk als das Zwischenglied verwendet worden wäre.

Industrielle Anwendbarkeit

[0061] Die vorliegende Erfindung bezieht sich auf eine dreidimensionale Führungsvorrichtung und kann vorzugsweise bei einer Schwingungsisolationsvorrichtung zur Isolation von Gebäuden von Schwingungen verwendet werden.

Patentansprüche

1. Dreidimensionale Führungsvorrichtung mit einer Basis, mit einer ersten gekrümmten Führungsvorrichtung, die an der Basis befestigt ist und eine bogenförmige Spur besitzt, weiter mit einer zweiten gekrümmten Führungsvorrichtung, die über der ersten gekrümmten Führungsvorrichtung angeordnet ist und eine Bewegungsebene entlang einer bogenförmigen Spur hat, die die Bewegungsebene der ersten gekrümmten Führungsvorrichtung kreuzt, und mit einem Zwischenglied, welches zwischen der ersten gekrümmten Führungsvorrichtung und der zweiten gekrümmten Führungsvorrichtung positioniert ist und die erste gekrümmte Führungsvorrichtung und die zweite gekrümmte Führungsvorrichtung verbindet,
wobei jede der ersten und zweiten gekrümmten Führungsvorrichtungen Folgendes aufweist:
eine Spurschiene, die vertikal mit einer vorbestimmten Krümmung gekrümmtist und eine Vielzahl von Roll- bzw. Wälzelementlaufnuten besitzt, die in Außenflächen davon definiert sind;
einen Lagerblock, der einen im Wesentlichen zylindrischen starren Körper aufweist und in Innenflächen davon eine Vielzahl von Wälzelementlaufnuten in Ausrichtung mit den Wälzelementlaufnuten in der Spurschiene aufweist, und nicht belastete Wälzelementrolldurchlässe benachbart zu den Wälzelementlaufnuten;
ein Paar von Deckeln, die jeweils an den vorderen und hinteren Enden des Lagerblockes montiert sind und jeweilige Wälzelementrichtungsumlenkdurchlässe besitzen, die in jeweiligen Innenflächen davon definiert sind, wobei die Wälzelementrichtungsumlenkdurchlässe die Enden der Wälzelementlaufnuten und der nicht belasteten Wälzelementdurchlässe verbin-

den und einen endlosen Wälzelementumlaufpfad vorsehen; und
eine Vielzahl von Wälzelementen, die angeordnet sind, um in dem endlosen Wälzelementumlaufpfad zu zirkulieren, um Lasten zwischen den Wälzelementlaufnuten in der Spurschiene und den Wälzelementlaufnuten in dem Lagerblock zu tragen;
wobei das Zwischenglied einen starren Körper in Form eines Blockes aufweist und offene zylindrische Ausnehmungen besitzt, die jeweils in den zwei Oberflächen davon definiert sind, wobei die Lagerblöcke drehbar in die offenen zylindrischen Ausnehmungen eingepasst sind.

2. Dreidimensionale Führungsvorrichtung nach Anspruch 1, wobei die zylindrischen Ausnehmungen jeweils in oberen und unteren Oberflächen des Zwischengliedes definiert sind.

3. Dreidimensionale Führungsvorrichtung nach Anspruch 1, wobei das Zwischenglied die zylindrischen Ausnehmungen besitzt, die jeweils in den unteren und seitlichen Oberflächen davon definiert sind.

4. Dreidimensionale Führungsvorrichtung nach Anspruch 1, wobei das Zwischenglied die zylindrischen Ausnehmungen jeweils in beiden Seitenflächen davon definiert hat.

5. Dreidimensionale Führungsvorrichtung nach einem der Ansprüche 1 bis 4, wobei das Zwischenglied die zylindrischen Ausnehmungen besitzt, die in jeweiligen Positionen definiert sind, so dass der mittlere Teil von einem der Lagerblöcke und die mittlere Position des anderen Lagerblockes in einer Ebene verschoben sind, um die zwei senkrechten Spurschienen nahe aneinander zu bringen.

(54) Bezeichnung: **Apparat mit Endlos-Gleitführung**

Beschreibung

[0001] Die Erfindung betrifft eine endlose Gleitführungsvorrichtung, z. B. eine geradlinige Führungsvorrichtung, eine krummlinige Führungsvorrichtung, ein Drehlager o. ä., und insbesondere eine solche Art von endloser Gleitführungsvorrichtung, die aufweist: eine Spurschiene, einen entlang der Spurschiene beweglichen Gleittisch und Wälz- bzw. Rollkörper, die zwischen der Spurschiene und dem Gleittisch rollen, während sie eine Last tragen, wobei ein Leerlaufrollweg, ein Innenumfangsabschnitt eines Richtungsänderungswegs und/oder ein Rollkörperhalteabschnitt eines Lastrollwegs des Gleittisches durch Kunstharz-Rollkörperführungsteile gebildet ist, die durch Einsatzformen unter Verwendung eines Lauf- bzw. Lagerrings als Kern hergestellt sind.

[0002] Bei verschiedenen Arten endloser Gleitführungsvorrichtungen, die jeweils mit einem Lager versehen sind, ist die Linearbewegung oder Drehbewegung von Rollkörpern, z. B. Kugeln oder Rollen, zwischen einer Spurschiene und einem Gleittisch ermöglicht, indem die Rollbewegung der Rollkörper genutzt wird, um (1) das Herausfallen der Rollkörper zu verhindern, wenn der Gleittisch von der Spurschiene getrennt wird, (2) den Reibungswiderstand zu reduzieren, indem verhindert wird, daß die Rollkörper miteinander in Kontakt kommen, und (3) zu veranlassen, daß sich die Rollkörper gleichmäßig bewegen, indem sie in einer Linie an einer vorbestimmten Position gebildet werden, wobei in der Praxis eine Anzahl solcher Rollkörper zwischen der Spurschiene und dem Gleittisch durch Verwendung eines Korbs oder Käfigs aus metallischem Dünnblech oder Kunstharz eingebaut sind.

[0003] In einem den Korb nutzenden Verfahren ist es aber nötig, eine Endlosspur für die Rollkörper zu bilden, indem der Korb im Gleittisch so montiert wird, daß die Rollkörper in der Endlosspur eingebaut sind, wobei aber solche Probleme vorliegen, daß Fertigkeiten zum Montieren des Korbs erforderlich sind und es schwierig ist, die Montage zu automatisieren. Da ferner in einem Verfahren unter Verwendung des Käfigs der Käfig im Gleittisch montiert wird, während eine Anzahl von Rollkörpern drehbar im Käfig festgehalten werden, kommt es trotz der Tatsache, daß die Rollkörper leicht in den Gleittisch eingebaut werden können, zu einem weiteren Problem, daß es nötig wird, die Anzahl von Rollkörpern in jeweiligen Taschen des Käfigs vorab einzubauen, so daß ein hoher Arbeits- und Kostenaufwand erforderlich ist, um den Käfig mit einer Anzahl darin eingebauter Rollkörper herzustellen.

[0004] In der EP-A-743456, die alle Merkmale des Oberbegriffs von Anspruch 1 zeigt, sind diese Probleme gelöst, indem sie eine endlose Gleitführungsvorrichtung bereitstellt, in der ein Gleittisch mit einer Endlosspur für Rollkörper mit einem Lastrollweg, einem Leerlaufrollweg und einem Richtungsänderungsweg durch einen Lagerring gebildet ist, der mindestens folgendes hat: einen Lastrollweg, Kunstharz-Rollkörperführungsteile, die durch Einsatzformen unter Verwendung des Lagerrings als Kern hergestellt sind und jeweils einen Leerlaufrollweg, einen Innenumfangsabschnitt eines Richtungsänderungswegs und/oder einen Rollkörperhalteabschnitt eines Lastrollwegs haben, und ein Paar Kunstharzdeckel, die jeweils sowohl an einem vorderen als auch an einem hinteren Ende des Lagerrings mit den Rollkörperführungsteilen befestigt sind und jeweils einen Außenumfangsabschnitt auf ihrer Innenfläche haben, der einen Richtungsänderungsweg neben der o. g. Innenumfangsfläche bildet.

[0005] Da bei dieser endlosen Gleitführungsvorrichtung ein Teil oder der Großteil der Endlosspur des Gleittischs durch die Kunstharz-Rollkörperführungsteile gebildet ist, die durch Einsatzformen unter Verwendung eines Lagerrings als Kern hergestellt sind, hat die Vorrichtung die Vorteile, daß die Endlosspur genau gebildet sein kann, das Rollen der Rollkörper in der Endlosspur extrem gleichmäßig wird, das Gleiten des Gleittischs entlang der Spurschiene gleichmäßig wird, der Geräuschpegel minimiert sein kann und die Herstellung des Gleittischs mit den darin eingebauten Rollkörpern zur Automatisierung erleichtert ist.

[0006] Wird aber ein Gleittisch einer endlosen Gleitführungsvorrichtung durch dieses Verfahren hergestellt, liegt mitunter ein Fall vor, in dem Rollkörperführungsteile, hergestellt durch Einsatzformen unter Verwendung eines Lagerrings als Kern, insbesondere ein ihre Ecken abdeckender Abschnitt, zum Reißen neigen (im folgenden als "Eckenreißen" bezeichnet), was manchmal zur Produktion eines fehlerhaften Erzeugnisses oder zur Verkürzung der Lebensdauer des Produkts führt.

[0007] Daher wurde als Ergebnis von Untersuchungen zur Ursache einer solchen Eckenrißbildung im Rahmen der Erfindung festgestellt, daß sich bei Herstellung der Rollkörperführungsteile durch Einsatzformen unter Verwendung eines Lagerrings als Kern zwangsläufig eine Spannung an dem jede der Ecken des Lagerrings abdeckenden Abschnitt im Verlauf der Abkühlung des Harzmaterials konzentriert, so daß während dieses Abkühlungsverfahrens oder danach dieser Abschnitt reißanfällig ist.

[0008] Das heißt, ist bei Anordnung des Lagerrings als Kern in einer Form und Einspritzen eines geschmolzenen Harzmaterials in die Form, um so Rollkörperführungsteile durch Einsatzformen zu bilden, ein dicker Abschnitt des Harzmaterials nahe jeder der Ecken des Lagerrings vorhanden, wird dieses Reißproblem auffällig. Grund dafür ist, daß das geschmolzene Harzmaterial am Abschnitt, der jede der Ecken des Lagerrings abdeckt, zuerst erstarrt, und wird dann der dicke Abschnitt des Harzmaterials nahe jeder der Ecken abgekühlt, um zu erstarren, erstarrt das geschmolzene Harz von seiner Oberfläche in Kontakt mit der metallischen Oberfläche des Lagerrings oder der Form zu seinem Inneren unter Bildung einer sogenannten "Einfallstelle", so daß der anfangs erstarrte Abschnitt des Harzes, der jede der Ecken des Lagerrings bedeckt, gedehnt wird, wodurch eine übermäßige Spannung auf diesen Abschnitt ausgeübt wird, die zur Bildung eines Risses an der Ecke führt.

[0009] Als Wege zur Lösung eines solchen Problems betrachtet man mehrere Verfahren, in denen die Dicke des Harzes vergleichmäßigt wird, damit das gesamte Harz mit einer konstanten Geschwindigkeit abgekühlt werden kann, das Harz in der Form langsam abgekühlt wird, während man eine Verweilzeit einhält (d. h. Einhaltung einer langen Abkühlungszeit in der Form), oder die Abkühlungsgeschwindigkeit verlangsamt wird. Aber auch wenn die Dicke des Harzes vergleichmäßigt wird, kann das Eckenreißproblem nicht vollständig überwunden werden, wozu kommt, daß die Verlängerung der Abkühlungszeit in der Form oder die Verlangsamung der Abkühlungsgeschwindigkeit zu einem starken Produktivitätsrückgang führt, so daß man von keinem dieser Verfahren behaupten kann, es sei eine befriedigende Lösung für das Problem.

[0010] Als Ergebnis beharrlicher Untersuchungen zu Wegen zur Lösung dieses Problems wurde daher im Rahmen der Erfindung festgestellt, daß dieses Eckenreißproblem gelöst werden kann, indem die Rollkörperführungsteile mit einer spezifischen Formmasse geformt werden, insbesondere wenn die Rollkörperführungsteile durch Einsatzformen unter Verwendung eines Lagerrings als Kern geformt werden.

[0011] Somit besteht eine Aufgabe der Erfindung darin, eine endlose Gleitführungsvorrichtung bereitzustellen, die frei vom "Eckenreiß"-Problem ist und die eine lange Nutzungsdauer hat. Dieses Problem wird durch Anspruch 1 gelöst.

[0012] Die erfindungsgemäße Führungsvorrichtung hat verschiedene Vorteile wie folgt: Da die Vorrichtung mit den Kunstharz-Rollkörperführungsteilen versehen ist, die durch Einsatzformen unter Verwendung eines Lagerrings als Kern hergestellt sind und die einen Teil oder den Großteil der Endlosspur des Gleittischs bilden, ist die Endlosspur genau gebildet, damit die Rollkörper recht gleichmäßig rollen können, der Geräuschpegel reduziert ist, und die Verarbeitbarkeit bei der Herstellung des Gleittischs mit den darin eingebauten Rollkörpern verbessert ist, um zu ermöglichen, die Herstellung des Gleittischs zu automatisieren.

[0013] Das heißt, die erfindungsgemäße endlose Gleitführungsvorrichtung weist auf: eine Spurschiene, einen entlang der Spurschiene beweglichen Gleittisch und mehrere Rollkörper, die zwischen der Spurschiene und dem Gleittisch rollen, während sie eine Last tragen, wobei der Gleittisch aufweist: einen Lagerring mit einer Endlosspur mit einem Lastrollweg, einem Leerlaufrollweg und einem Richtungsänderungsweg und mindestens eine Lastrollfläche, Kunstharz-Rollkörperführungsteile, die durch Einsatzformen unter Verwendung des Lagerrings als Kern hergestellt sind und einen Leerlaufrollweg, einen Innenumfangsabschnitt eines Richtungsänderungswegs und/oder einen Rollkörperhalteabschnitt eines Lastrollwegs haben, und ein Paar Kunstharzdeckel, die am vorderen bzw. hinteren Ende des Lagerrings befestigt sind und jeweils auf ihrer Innenfläche einen Außenumfangsabschnitt zum Bilden eines Richtungsänderungswegs neben dem o. g. Innenumfangsabschnitt haben, wobei die Rollkörperführungsteile durch Verwendung eines Materials geformt sind, das den Relationsausdruck $(a \times b) \div c \geq 700$ MPa erfüllt.

[0014] In der Erfindung muß das Material zum Formen der Rollkörperführungsteile den Relationsausdruck $(a \times b) \div c \geq 700$ MPa oder vorzugsweise $(a \times b) \div c \geq 800$ MPa im Hinblick auf die Zugfestigkeit a (MPa), die Verlängerung bei Zug b (%) und das Formschrumpfmaß c (%) erfüllen, was man durch Verwendung eines Prüfkörpers von 120 mm × 120 mm × 2 mm erhält, der unter den Standardformbedingungen geformt wird (Spritzgießdruck: 500 kp/cm^2, Zylindertemperatur: 240°C, Formtemperatur: 70°C, Einspritzgeschwindigkeit: 3,5 m/min, Zyklus: Verweilen 25 s und Abkühlen 10 s sowie Anguß 4 W 2t). Liegt der Wert $(a \times b) \div c$ unter 700 MPa, wird bei Herstellung der Rollkörperführungsteile durch Einsatzformen unter Verwendung des Lagerrings als Kern oder nach deren Herstellung leicht ein Eckenriß erzeugt, so daß es unmöglich ist, die Nutzungsdauer des Erzeugnisses zu verlängern.

[0015] Als Formmassen, die die o. g. Anforderungen erfüllen, lassen sich grundsätzlich verschiedene Arten thermoplastischer Harzzusammensetzungen aufzählen, die aus thermoplastischen Harzen, z. B. Polyolefin, ABS, Nylon, Polybutylenterephthalat, Polyacetal, denaturiertes Polyphenylenoxid, Polyphenylensulfid u. ä., in Mischung in verschiedenen Verhältnisses mit vielfältigen Arten von Mineralfasern (als Füllmittel), z. B. Glasfaser, Mineralwollefasern, Kohlenstoffasern, Kaliumtitanatwhisker u. ä., bestehen. Ferner können zu diesen Harzzusammensetzungen Zusatzstoffe zugegeben sein, z. B. Färbemittel wie Pigmente, Wärmestabilisatoren, Flammenhemmstoffe, Antistatikmittel u. ä.

[0016] Da die Rollkörperführungsteile eine vergleichsweise komplizierte Form haben und vergleichsweise harten Bedingungen ausgesetzt sind und unter Berücksichtigung der Formbarkeit, Wärmefestigkeit, Gleitfähigkeit und des Elastizitätsmoduls der Formmassen, ist bevorzugt, von diesen thermoplastischen Harzzusammensetzungen Nylon, Polybutylenterephthalat und Polypropylen als thermoplastische Harze zu verwenden und Kaliumtitanatwhisker, Kohlenstoffaser und Glasfaser als Füllmittel zu nutzen, und besonders unter dem Gesichtspunkt der Formbarkeit ist die Verwendung solcher Materialien mit einem Schmelzindex über 15, vorzugsweise über 25, stärker bevorzugt. Ferner ist die am stärksten erwünschte der thermoplastischen Harzzusammensetzungen eine Zusammensetzung mit einem Schmelzindex von 15 bis 35, die man durch Mischen von 2 bis 5 Gew.-% Kaliumtitanatwhiskern in Polybutylenterephthalat erhält. Durch Einsatz dieser thermoplastischen Harzzusammensetzung als Formmasse für die Rollkörperführungsteile ist es nicht nur möglich, die Bildung von Rissen an jeder der Ecken der so hergestellten Rollkörperführungsteile des Gleittischs der endlosen Gleitführungsvorrichtung zu verhindern, sondern auch die Nutzungsdauer des Erzeugnisses stark zu verbessern.

[0017] Zudem verfügt in der Erfindung jedes der Rollkörperführungsteile, die über einem Lagerring unter Verwendung einer Formmasse in einem Stück gebildet sind, über einen Leerlaufrollweg, eine Innenumfangsfläche eines Richtungsänderungswegs und/oder einen Rollkörperhalteabschnitt eines Lastrollwegs, wodurch die gesamte Endlosspur für die Rollkörper genau gebildet sein kann.

[0018] Eine erfindungsgemäße endlose Gleitführungsvorrichtung kann sein: eine geradlinige Gleitführungsvorrichtung mit einem Gleittisch, der lineare Hin- und Herbewegungen auf einer Spurschiene vollführen kann, während er eine Last trägt, eine endlose krummlinige Führungsvorrichtung mit einem Gleittisch, der krummlinige Hin- und Herbewegungen auf einer krummlinigen Spurschiene mit einem vorbestimmten Krümmungsradius vollführen kann, und ein Kipplager mit einem block- oder kreisförmigen Gleittisch, der entlang einer kreisförmigen Spurschiene kippen kann, und als Rollkörper, die zwischen der Spurschiene und dem Gleittisch rollen, können Kugeln oder Walzen verwendet werden.

[0019] Da wie zuvor beschrieben in einer erfindungsgemäßen endlosen Gleitführungsvorrichtung die Rollkörperführungsteile, die durch Einsatzformen unter Verwendung eines Lagerrings gebildet sind, aus einer Formmasse hergestellt sind, die den Relationsausdruck $(a \times b) \div c \geq 700$ MPa erfüllt, ist ein Teil oder der Großteil der Endlosspur des Gleittischs genau gebildet, so daß das Rollen der Rollkörper recht gleichmäßig wird, der Geräuschpegel gesenkt ist und die Verarbeitungsfähigkeit bei Herstellung des Gleittischs mit den darin eingebauten Rollkörpern verbessert ist, damit die Herstellung automatisiert sein kann. Ferner läßt sich das Problem von "Eckenrissen" an den Rollkörperführungsteilen beseitigen, während die zuvor beschriebenen Vorteile unverändert gewahrt bleiben, so daß die Anzahl fehlerhafter Produkte minimiert und die Nutzungsdauer des Produkts stark verbessert sein kann.

[0020] Im folgenden wird die beste Durchführungsweise der Erfindung anhand von bevorzugten Ausführungsformen der Erfindung beschrieben, die in den beigefügten Zeichnungen gezeigt sind. Es zeigen:

[0021] **Fig.** 1 eine (teilweise im Schnitt gezeigte) Vorderansicht einer endlosen geradlinigen Gleitführungvorrichtung gemäß einer Ausführungsform der Erfindung;

[0022] **Fig.** 2 eine (teilweise im Schnitt gezeigte) Seitenansicht der geradlinigen Führungsvorrichtung von **Fig.** 1;

[0023] **Fig.** 3 eine Perspektivansicht eines Lagerrings, von Rollkörperführungsteilen und eines von Deckeln, die zusammen einen Gleittisch der endlosen geradlinigen Gleitführungsvorrichtung von **Fig.** 1 bilden;

[0024] **Fig.** 4 eine Schnittansicht eines Lagerrings von **Fig.** 2;

[0025] **Fig.** 5 eine Schnittansicht des Lagerrings von **Fig.** 4, insbesondere wenn er in einer Form angeordnet ist; und

[0026] **Fig.** 6 eine Schnittansicht von Kugelhalteteilen, die im Lagerring durch die Form von **Fig.** 5 vorgesehen sind.

Ausführungsform 1

[0027] In **Fig.** 1 und 2 ist eine endlose geradlinige Gleitführungsvorrichtung gemäß einer ersten Ausführungsform der Erfindung gezeigt. Diese geradlinige Führungsvorrichtung verfügt grundsätzlich über eine Spurschiene **1**, einen entlang der Spurschiene **1** beweglichen Gleittisch **2** und Kugeln **3a**, die zwischen der Spurschiene **1** und dem Gleittisch **2** rollen, während sie eine Last tragen.

[0028] Die Spurschiene **1** ist mit einer kreisbogenförmigen Kugelrollrille **1a** versehen, in der eine Kugel **3a** zwischen der Spurschiene **1** und dem Gleittisch **2** rollt, während sie eine Last trägt. Ferner verfügt der Gleittisch **2** über einen Lagerring **4** mit einer kreisbogenförmigen Lastkugelrille (Lastrollfläche) **4a**, die gegenüber der Kugelrollrille **1a** der Spurschiene **1** liegt und in der die Lastkugel **3a** rollt, Kunstharz-Kugelführungsteile (Rollkörperführungsteile) **5**, die durch Einsatzformen gebildet sind, wobei der Lagerring **4** als Kern dient, und ein Paar Kunstharzdeckel **6**, die am vorderen bzw. hinteren Ende des Lagerrings **4** befestigt sind.

[0029] Ferner verfügt jedes der Kugelführungsteile **5** über ein Kugelaustrittsloch (Leerlaufrollweg) **5a**, das entlang der Innenumfangswand eines Durchgangslochs **4b** für eine Leerlaufkugel **3b** gebildet ist, die im Lagerring **4** beim Formen vorgesehen ist, einen im wesentlichen halbkreisförmigen Innenumfangsabschnitt **5b**, der einen Richtungsänderungsweg zum Ändern der Rollrichtung der Leerlaufkugel **3b** von einem Lastbereich zu einem Leerlaufbereich oder umgekehrt bildet, und Kugelhalteabschnitte **5c**, die auf beiden Seiten der Lastkugelrille **4a** des Lagerrings **4** gebildet und geeignet sind, die in der Lastkugelrille **4a** rollende Lastkugel **3a** am Hergleiten zu hindern, wenn die Spurschiene **1** aus dem Gleittisch **2** gezogen wird. Ferner hat jeder der Deckel **6** auf der Seite seiner Innenfläche einen im wesentlichen halbkreisförmigen Außenumfangsabschnitt **6a** zum Bilden eines Richtungsänderungswegs für die Leerlaufkugel **3b** zusammen mit dem Innenumfangsabschnitt **5b** des Kugelführungsteils **5**, was eine Endlosspur für die Kugeln **3** durch die durch das Kugelaustrittsloch **5a** gebildeten Leerlaufrollwege, die durch die Innenumfangsabschnitte **5b** der Kugelführungsteile **5** und die Außenumfangsabschnitte **6a** der Deckel **6** gebildeten Richtungsänderungswege und die durch die Kugelhalteabschnitte **5c** der Kugelführungsteile **5** gebildeten Lastrollwege bildet.

[0030] In dieser Ausführungsform 1 erhält man jedes der Kugelführungsteile **5** durch Formen einer thermoplastischen Harzzusammensetzung, die aus Polybutylenterephthalat (PBT) besteht, das mit 3,5 Gew.-% Kaliumtitanatwhiskern gemischt ist (Produktbezeichnung TISMO von Otsuka Chemical Co., Ltd.) und die in Tabelle 1 in der folgenden Ausführungsform angegebenen physikalischen Eigenschaften hat.

[0031] Zunächst wurde gemäß **Fig.** 4 ein Lagerring **4** mit vier Reihen Lastkugelrillen **4a** und zwei Reihen Durchgangslöchern **4b** für eine Leerlaufkugel **3b** aus einem Stahlmaterial hergestellt. Als nächstes wurde gemäß **Fig.** 5 der Lagerring **4** durch eine Abstützung **8** in einem durch ein Paar Formteile **7a** und **7b** gebildeten Hohlraum abgestützt, vier stabförmige Teile **9** zum Bilden von Kugelaustrittslöchern **5a** wurden jeweils an vorbestimmten Positionen angeordnet, wodurch Spalte **10a**, **10b**, **10c** und **10d** gebildet wurden, und eine Schmelze der o. g. thermoplastischen Harzzusammensetzung wurde unter vorbestimmten Bedingungen eingespritzt, so daß gemäß **Fig.** 6 die Kunstharz-Kugelführungsteile **5** in einem Stück mit den vorbestimmten Abschnitten des Lagerrings **4** hergestellt wurden.

[0032] Das Spritzgießen der Kugelführungsteile **5** erfolgte mit Hilfe einer Inline-Schneckenspritzgießmaschine unter folgenden Bedingungen: Temperatur der Harzschmelze 240°C, Einspritzdruck 400 bis 700 kp/cm^2, Formtemperatur 40 bis 80°C und Einspritzgeschwindigkeit 2,5 bis 6,0 m/min.

[0033] Ferner wurde eine Wärmeschockprüfung an den in der Ausführungsform 1 gebildeten Kugelführungsteilen **5** mit Hilfe einer von Satake Chemical Machine Industry Co., Ltd. hergestellten Wärmeschock-Prüfmaschine durchgeführt, in der die Probe niedrigen/hohen Temperaturen von –20°C bis +60°C eine Stunde ausgesetzt wurde, wozu eine 10-minütige Temperaturanstiegszeit und eine 10-minütige Temperaturabfallzeit gehörten. Zusätzlich erfolgte ein Durchwärmversuch bei hoher Temperatur an der Probe unter Verwendung einer mit Heißluftumlauf und konstanter Temperatur arbeitenden Trocknungsmaschine von Satake Chemical Machine Industry Co., Ltd. bei einer gesteuerten Temperatur von 100 ± 2°C. Die Ergebnisse dieser Versuche wurden nach den folgenden vier Kriterien gemäß Tabelle 1 bewertet:

⊙: Keine Eckenrisse und andere Haarrisse beobachtet.
O: Kein Eckenriß und kein Haarriß beobachtet, aber kleine Größenänderung festgestellt.
Δ: Weiße Flecken auf der Oberfläche der Probe beobachtet, aber kein Bruch oder Riß festgestellt.

X: Fehler wie Eckenrisse und Haarrisse beobachtet.

Ausführungsform 2

[0034] Eine thermoplastische Harzzusammensetzung, die mit 3,0 Gew.-% Kaliumtitanatwhiskern gemischt war und die physikalischen Eigenschaften gemäß Tabelle 1 hatte, wurde geformt, um Kugelführungsteile eines Gleittischs wie in der Ausführungsform 1 bereitzustellen, und das geformte Erzeugnis wurde bewertet, indem es einer Wärmeschockprüfung und einem Dauerwärmversuch bei hoher Temperatur unterzogen wurde, wobei die Ergebnisse in Tabelle 1 dargestellt sind.

Tabelle 1

		Ausführungsformen	
		1	2
Physikalische Eigenschaften der Harzzusammensetzung	Zugfestigkeit (MPa)	63	60
	Verlängerung bei Zug b (%)	49	16
	Formschrumpfmaß c (%)	1,5	1,3
	(a x b) ÷ c	2058	738
	Schmelzindex	18	30
Bewertung der Wärmeschockprüfung		⊙	O
Durchwärmversuch bei hoher Temperatur		⊙	O

[0035] Anhand der Ergebnisse von Tabelle 1 wurde festgestellt, daß bei Herstellung der Kugelführungsteile durch Verwendung einer Harzzusammensetzung mit einem Wert des Relationsausdrucks (a × b) ÷ c über 700 MPa, der auf der Grundlage der Zugfestigkeit a, der Verlängerung bei Zug b und des Formschrumpfmaßes c erhalten wurde, ein Produkt erhalten werden konnte, das praktisch keine Problem im Hinblick auf seine Leistung und Nutzungsdauer im Zusammenhang mit der Bildung von Eckenrissen und anderen Haarrissen hatte.

Patentansprüche

1. Endlose Gleitführungsvorrichtung mit einer Spurschiene (**1**), einem entlang der Spurschiene beweglichen Gleittisch (**2**) und mehreren Rollkörpern (**3a**), die zwischen der Spurschiene und dem Gleittisch rollen, während sie eine Last tragen, wobei der Gleittisch mit einer Endlosspur versehen ist, die aufweist: einen Lastrollweg (**4a**), einen Leerlaufrollweg (**5a**) und einen Richtungsänderungsweg (**5b**), einen Lagerring (**4**) mit mindestens einem Lastrollweg, Kunstharz-Rollkörperführungsteile (**5**), die durch Einsatzformen unter Verwendung des Lagerrings (**4**) als Kern gebildet sind und jeweils einen Leerlaufrollweg (**5a**), einen Innenumfangsabschnitt eines Richtungsänderungswegs (**5b**) und/oder einen Rollkörperhalteabschnitt (**5c**) eines Lastrollwegs haben, und ein Paar Kunstharzdeckel (**6**), die sowohl am vorderen als auch am hinteren Ende des Lagerrings (**4**) befestigt sind und jeweils einen Außenumfangsabschnitt auf einer Innenfläche von ihnen haben, um den Richtungsänderungsweg neben dem Innenumfangsabschnitt jedes der Rollkörperführungsteile (**5**) zu bilden, **dadurch gekennzeichnet**, daß die Rollkörperführungsteile (**5**) durch Verwendung eines Materials geformt sind, das den Relationsausdruck (a × b) ÷ c ≥ 700 MPa im Hinblick auf die Zugfestigkeit a (MPa), die Verlängerung bei Zug b (%) und das Formschrumpfmaß c (%) erfüllt.

2. Endlose Gleitführungsvorrichtung nach Anspruch 1, wobei jedes der Rollkörperführungsteile (**5**) den Leerlaufrollweg (**5a**), den Innenumfangsabschnitt des Richtungsänderungswegs (**5b**) und den Rollkörperhalteabschnitt (**5c**) des Lastrollwegs aufweist.

3. Endlose Gleitführungsvorrichtung nach Anspruch 1 oder 2, wobei das Material zum Formen der Rallkörperführungsteile (**5**) eine thermoplastische Harzzusammensetzung ist, die einen Schmelzindex über 15 hat und aus einer oder mehreren Arten thermoplastischer Harze besteht, die aus Polybutylenterephthalat, Polyacrylnitril, Polybutadienstyrol und Polycarbonat unter Zugabe eines anorganischen Faserfüllmaterials ausgewählt sind.

4. Endlose Gleitführungsvorrichtung nach Anspruch 3, wobei das Material zum Bilden der Rollkörperführungsteile (**5**) aus einer thermoplastischen Harzzusammensetzung mit einem Schmelzindex von 15 bis 35 besteht, die durch Zugabe von 2 bis 5 Gew.-% Kaliumtitanatwhiskern zu Polybutylenterephthalat erhalten wird.

Beschreibung

Technisches Gebiet

[0001] Die Erfindung betrifft einen Kugelverbinder, in dem eine Anzahl von Kugeln in einer Reihe angeordnet ist und rollfähig gehalten wird und der verwendet wird, indem er z. B. in eine Linearführungsvorrichtung zum Endlosgleiten und eine Kugelendloslaufbahn einer Kugelspindelvorrichtung integriert ist, und insbesondere einen Kugelverbinder, der bei seiner Verwendung frei verbogen oder verdreht werden kann.

Hintergrund der Technik

[0002] Herkömmlich bekannt als Linearführungsvorrichtung zum Führen eines beweglichen Körpers, z. B. eines Tischs o. ä., entlang einer feststehenden Einheit, z. B. einem Bett o. ä., ist ein Lineargleitlager, in dem ein Gleitsockel, der einen beweglichen Körper, z. B. einen Tisch o. ä., trägt, entlang einer Laufschiene bewegt wird, die an einer feststehenden Einheit, z. B. einem Bett, einem Sattel o. ä., angeordnet ist, oder eine Kugelkeilvorrichtung, in der ein zylindrisches Mutternteil, das auf eine Keilwelle aufgepaßt ist, entlang der Keilwelle über Kugeln bewegt wird.

[0003] Von diesen ist als erstgenanntes Lineargleitlager ein Aufbau bekannt, der aufweist: eine Laufschiene mit einer Kugelrollrille, einen Gleitsockel mit einer der Kugelrollrille gegenüberliegenden Lastrollrille sowie einem Kugelrücklaufloch parallel dazu, mit einem Richtungsänderungsweg zum Führen von Kugeln von der Lastrollrille zum Kugelrücklaufloch, die entlang der Laufschiene bewegt werden, und mit einer Anzahl von Kugeln, die zwischen dem Gleitsockel und der Laufschiene rollen, während sie belastet sind, und in einer Endloslaufbahn umlaufen, die durch die Lastrollrille, das Kugelrücklaufloch und den Richtungsänderungsweg des Gleitsockels gebildet ist.

[0004] Zudem ist als letztgenannte Kugelkeilvorrichtung ein Aufbau bekannt, der aufweist: eine Keilwelle mit einer Kugelrollrille entlang der Axialrichtung und ein Mutternteil, das eine der Kugelrollrille gegenüberliegende Lastrollrille hat und auf den Außenumfang der Keilwelle über Kugeln aufgepaßt ist, wobei das Mutternteil entlang der Keilwelle ähnlich wie in einem Endlosumlauf der Kugeln bewegt wird. Diese Vorrichtung wird verwendet, indem das Drehmoment zwischen dem Mutternteil und der Keilwelle gegenseitig übertragen wird.

[0005] Gemäß der herkömmlichen Linearführungsvorrichtung mit dem zuvor beschriebenen Aufbau ist die Endloslaufbahn eines Gleitteils, z. B. des Gleitsockels oder des Mutternteils, mit den Kugeln gefüllt, weshalb bei Bewegung des Gleitteils entlang der Laufschiene oder einem Führungsschaft, z. B. der Keilwelle, die einander benachbarten Kugeln in der Endloslaufbahn im Umlauf geführt werden, wobei sie miteinander kollidieren oder aneinander reiben, was das Problem aufwirft, daß die Kugeln frühzeitig verschleißen und die Lebensdauer der Vorrichtung verkürzt ist.

[0006] Zur Lösung dieses Problems wurde daher ein Lineargleitlager vorgeschlagen, bei dem ein Kugelverbinder, in dem eine Anzahl von Kugeln ausgerichtet ist und gehalten wird, in die Endloslaufbahn integriert ist (JP-A-5-52217). Wie Fig. 25 und Fig. 26 zeigen, sind gemäß einem solchen Kugelverbinder **200** Abstandshalter **202** zwischen jeweiligen einander benachbarten Kugeln **201** eingefügt, die Abstandshalter **202** sind durch ein Paar streifenartige Verbindungsteile **203** in Anordnungsrichtung der Kugeln verbunden, wodurch die Kugeln **201** rosenkranzförmig verbunden sind, und der Kugelverbinder wird dadurch hergestellt, daß flexibles Harz durch Spritzgießen geformt wird, wobei die Kugeln **201** in einem Werkzeug als Kerne angeordnet sind.

[0007] Gemäß dem herkömmlichen Lineargleitlager mit dem zuvor beschriebenen Aufbau ist der o. g. Kugelverbinder **200** gemäß Fig. 27 in ein Kugelrücklaufloch **205** und in Richtungsänderungswege **206** eines Gleitsockels **204** integriert und wird in der Endloslaufbahn im Umlauf geführt, und in diesem Fall sind die Abstandshalter **202** zwischen den einander benachbarten Kugeln **201** eingefügt, weshalb gegenseitige Reibung oder Kollision zwischen den Kugeln vermieden ist und Verschleiß der Kugeln **201** weitgehend verhindert werden kann.

[0008] Beim Umlaufen der Kugeln in der Endloslaufbahn muß die entlastete Kugel von der Kugelrollrille der Laufschiene zum Richtungsänderungsweg des Gleitsockels angehoben werden, und bei einem solchen Anhebevorgang gemäß Fig. 28 ist bevorzugt, die Kugel **201** in einer Richtung zu führen, in der eine Kugelrollrille **208** der Laufschiene **207** und eine Lastrollrille **209** des Gleitsockels **204** einander gegenüber liegen (im folgenden als Kugelkontaktrichtung bezeichnet). Grund dafür ist, daß bei Führung der Kugel **201** in einer solchen Richtung verhindert wird, daß die Kugel **201** im Richtungsänderungsweg **206** schlangenförmig läuft, und der Umlauf der Kugel **201** in der Endloslaufbahn des Gleitsockels **204** glatt erfolgt.

[0009] Aus Sicht der Vermeidung einer Vergrößerung des Gleitsockels **204** tritt der Fall auf, daß die Bildung des Kugelrücklauflochs **205** in Kugelkontaktrichtung nicht unbedingt ordnungsgemäß ist, und es tritt der Fall auf, daß das Kugelrücklaufloch **205** nicht in Kugelkontaktrichtung gebildet werden kann, weil es einem im Gleitsockel **204** zur Befestigung eines beweglichen Körpers, z.B. eines Tisches und der gleichen, gebildeten Gewindeloch im Wege wäre.

[0010] Um den Freiheitsgrad der Position für die Bildung des Kugelrücklauflochs **205** im Hinblick auf den Gleitsockel **204** zu erhöhen, während ein glatter Umlauf der Kugeln **201** in der Endloslaufbahn erreicht wird, muß sich also gemäß Fig. 29 der Richtungsänderungsweg **206** zum Führen der Kugeln von der Lastrollrille **209** zum Kugelrücklaufloch **205** gegenüber der Kugelkontaktrichtung biegen.

[0011] Berücksichtigt man ferner die dem Richtungsänderungsweg innewohnende Rolle bei der Rollrichtungsumkehr der Kugeln, ist bevorzugt, daß der Wenderadius der Kugeln in einem solchen Richtungsänderungsweg groß ist, wozu die Länge des Richtungsänderungswegs lang sein muß. Ist aber das Kugelrücklaufloch von der Lastrollrille aus gesehen in Kugelkontaktrichtung positioniert, kommt es bei großer Länge des Richtungsänderungswegs dazu, daß der Abstand zwischen der Lastrollrille und dem Kugelrücklaufloch natürlich verbreitert ist, und eine Vergrößerung des Gleitsockels läßt sich nicht vermeiden.

[0012] Auch angesichts dessen muß das Kugelrücklaufloch an einer beliebigen Position des Gleitsockels gebildet sein, und der Richtungsänderungsweg zum Verbinden des Kugelrücklauflochs mit der Lastrollrille muß eine Biegung bilden.

[0013] Da aber gemäß einem solchen herkömmlichen Kugelverbinder **200** Seitenkanten der streifenartigen Verbindungsteile **203** zum Verbinden der jeweiligen Abstandshalter **202** geradlinig sind, kommt es zu dem Problem, daß trotz der Tatsache, daß der Kugelverbinder **200** leicht in einer Richtung zu biegen ist, die die Stirnflächen der Verbindungsteile **203** schneidet (Pfeillinienrichtung A in Fig. 26), der Kugelverbinder **200** in einer Richtung parallel zu den Stirnflächen der Verbindungsteile **203** schwer zu biegen ist (Pfeillinienrichtung B in Fig. 25), wenn der Richtungsänderungsweg **206** so gebogen ist, daß er von der o. g. Kugelkontaktrichtung abweicht, weshalb sich der Kugelverbinder **200** in die Endloslaufbahn durch zwangsweises Biegen integrieren muß, so daß kein glatter Umlauf des Kugelverbinders **200** erwartet werden kann.

[0014] Betrachtet man daher gemäß der herkömmlichen Linearführungsvorrichtung unter Verwendung des Kugelverbinders den glatten Umlauf des Kugelverbinders in der Endloslaufbahn, muß von der Lastrollrille aus gesehen das Kugelrücklaufloch in Kugelkontaktrichtung gebildet sein, was ein Faktor für die Vergrößerung des Gleitsockels ist.

[0015] Gemäß der zuvor beschriebenen herkömmlichen Kugelkeilvorrichtung muß ferner aus Sicht der Verkleinerung des Mutternteils das Kugelrücklaufloch möglichst nahe am Innendurchmesser des Mutternteils eingebaut sein, und ähnlich wie beim zuvor erwähnten Lineargleitlager ist es schwierig, das Kugelrücklaufloch in Kugelkontaktrichtung von der Lastrollrille aus gesehen zu bilden.

[0016] Wird daher der herkömmliche Kugelverbinder gemäß Fig. 25 in die Endloslaufbahn der Kugelkeilvorrichtung integriert, läßt sich kein glatter Umlauf des Kugelverbinders erwarten.

[0017] Gemäß einer Kugelspindelvorrichtung, die zur Umwandlung von Drehbewegung eines Motors in Linearbewegung verwendet wird und die eine Linearführungseinheit einer Werkzeugmaschine o. ä. bildet, indem sie zusammen mit der o. g. Linearführungsvorrichtung zum Einsatz kommt, greifen eine Gewindespindel und ein Mutternteil über Kugeln ineinander ein, und das Mutternteil ist ähnlich mit einer Endloslaufbahn für die Kugeln versehen. Aus Sicht von Verschleißverhinderung der im Mutternteil umlaufenden Kugeln ist daher bevorzugt, daß auch in der Kugelspindelvorrichtung ein Kugelverbinder in die Endloslaufbahn integriert ist. Wie aber bereits erläutert, hat der herkömmliche Kugelverbinder einen Aufbau, der nur in spezifischen Richtungen leicht zu verbiegen ist, weshalb es schwierig ist, den Kugelverbinder in die Kugelendloslaufbahn der Kugelspindelvorrichtung zu integrieren.

[0018] Das heißt, beim Integrieren des Kugelverbinders in die Kugelendloslaufbahn der Kugelspindelvorrichtung muß sich der Kugelverbinder bezüglich des Spindelschafts spiralförmig wikkeln. Somit darf der Kugelverbinder nicht eben, sondern muß räumlich umlaufen, und beim. herkömmlichen Kugelverbinder mit kleinem Freiheitsgrad bezüglich der Biegerichtung läßt sich kein glatter Umlauf des Kugelverbinders in der Endloslaufbahn erwarten. Ist der Kugelverbinder in die Kugelspindelvorrichtung integriert, muß der Kugelverbinder in der Endloslaufbahn ferner in einem Zustand umlaufen, der mehr oder weniger mit Verdrehungen einhergeht, und bei Gebrauch des herkömmlichen Kugelverbinders mit einem geringen Freiheitsgrad bezüglich der Biegeleistung ist durch sein zwangsweises Verdrehen zu befürchten, daß sich die Kugeln aus dem Kugelverbinder lösen.

Offenbarung der Erfindung

[0019] Die Erfindung kam angesichts dieser Probleme zustande, und eine Aufgabe der Erfindung besteht darin, einen Kugelverbinder bereitzustellen, der sich in jeder Richtung nachgiebig verbiegen und in einer Kugelendloslaufbahn in einem Zustand umlaufen kann, in dem Kugeln auch dann festgehalten werden, wenn er verbogen, verdreht o. ä. ist.

[0020] Zudem besteht eine weitere Aufgabe der Erfindung darin, eine Linearführungsvorrichtung und eine Kugelspindelvorrichtung bereitzustellen, die einen solchen Kugelverbinder nutzen.

[0021] Ein erfindungsgemäßer Kugelverbinder ist ein Kugelverbinder, der aufgebaut ist aus einer Anzahl von Kugeln, die in einer Reihe mit vorbestimmten Abständen angeordnet sind, und einem flexiblen Verbindergurt (Band, Gürtel) zum drehbaren Halten der Kugeln und gegenseitigen Verbinden der einander benachbarten Kugeln, wobei der Verbindergurt vier Gurtteile aufweist, die in streifenartiger Form entlang von Umfangsflächen der Kugeln gebildet und mit den mehreren Kugeln in Kontakt gebracht sind, wobei die Gurtteile mit anderen Gurtteilen an Zwischenstellen der einander benachbarten Kugeln gegenseitig verbunden sind und der Verbindergurt in einer Form ausgebildet ist, die im Vergleich zu dem Außendurchmesser der Kugeln an Positionen der die Kugeln verbindenden Zwischenstellen eingeschnürt ist.

[0022] Gemäß einer Linearführungsvorrichtung der Erfindung unter Nutzung des Kugelverbinders ist ferner die Linearführungsvorrichtung aufgebaut aus einem Führungsschaft mit Kugelrollrillen zum Abrollen von Kugeln in Längsrichtung und einem Gleitteil mit Lastrollrillen zum Abrollen der lasttragenden Kugeln zwischen dem Führungsschaft und den Lastrollrillen, das Endloslaufbahnen zum Umlauf der Kugeln hat und entlang dem Führungsschaft entsprechend dem Umlauf der Kugeln bewegt wird, wobei der Kugelverbinder in eine der Endloslaufbahnen integriert ist und der Kugelverbinder entsprechend einer Relativbewegung zwischen dem Führungsschaft und dem Gleitteil in der Endloslaufbahn im Umlauf geführt wird.

[0023] Ferner ist gemäß einer Kugelspindelvorrichtung der Erfindung unter Verwendung des Kugelverbinders die Kugelspindelvorrichtung aufgebaut aus einem Spindelschaft mit Kugelrollrillen in Spiralform zum Abrollen von Kugeln an Außenumfangsflächen davon und einem Mutternteil mit Lastrollrillen in Spiralform zum Abrollen der lasttragenden Kugeln zwischen dem Spindelschaft und den Lastrollrillen, das Endloslaufbahnen zum Umlauf der Kugeln hat und auf den Spindelschaft über die Kugeln aufgeschraubt ist, wobei der Kugelverbinder in eine der Endloslaufbahnen integriert ist und der Kugelverbinder gemäß einer Relativbewegung zwischen dem Spindelschaft und dem Mutternteil in der Endloslaufbahn im Umlauf geführt wird.

[0024] Gemäß dem Kugelverbinder der Erfindung ist der Verbindergurt mit vier Gurtteilen versehen, die in streifenartiger Form entlang den Kugelflächen der Kugeln gebildet und mit den mehreren Kugeln in Kontakt gebracht sind, die Gurtteile sind mit anderen Gurtteilen an den Zwischenstellen der einander benachbarten Kugeln gegenseitig verbunden, weshalb die einzelnen Kugeln in einen Zustand gebracht sind, in dem sie durch die Gurtteile aus vier Richtungen umfaßt sind, und die Kugeln lösen sich auch dann nicht vom Verbindergurt, wenn der Kugelverbinder stark verbogen oder verdreht wird.

[0025] Auch wenn das Gleitteil der Linearführungsvorrichtung von der Laufschiene abgezogen oder wenn das Mutternteil der Kugelspindelvorrichtung vom Spindelschaft entfernt wird, läßt sich somit ohne Verwendung eines Kugelkäfigs verhindern, daß sich die Kugeln vom Gleitteil oder Mutternteil lösen.

[0026] Ferner ist der Verbindergurt in einer Form ausgebildet, die im Vergleich zum Außendurchmesser der Kugeln an Positionen eingeschnürt ist, an denen die vier Gurtteile miteinander gekoppelt sind, d. h. an Zwischenstellen der einander benachbarten Kugeln, weshalb der Kugelverbinder so einen Aufbau hat, daß er in jeder Richtung an diesen Positionen nachgiebig leicht verbogen werden und auf den Kugelverbinder ausgeübte Verdrehungen leicht aufnehmen kann. Bei seiner Verwendung läßt sich der Kugelverbinder daher in freier Richtung hinsichtlich der Kugelreihe verbiegen oder verdrehen, unabhängig von den Positionen, an denen die Gurtteile gebildet werden, und auch in einer solchen Situation kann der Kugelverbinder in der Endloslaufbahn glatt im Umlauf geführt werden.

Kurze Beschreibung der Zeichnungen

[0055] Fig. 29 ist eine Umrißansicht zur Darstellung eines Kugelumlaufverhaltens in dem Fall, in dem das Kugelrücklaufloch an einer von der Kugelkontaktrichtung abweichenden Position bezogen auf die Lastrollrille vorhanden ist.

Bezugszeichenliste

1 Kugelverbinder,
2 Verbindergurt,
3 Kugel,
4 Verbindungsabschnitt,
5 Gurtteil

[0056] Bevorzugte Ausführungsformen der Erfindung Anhand der beigefügten Zeichnungen werden im folgenden ein Kugelverbinder sowie eine einen erfindungsgemäßen Kugelverbinder nutzende Linearführungsvorrichtung und Kugelspindelvorrichtung näher beschrieben.

[0057] Fig. 1 zeigt eine Ausführungsform eines erfindungsgemäßen Kugelverbinders **1**. Gemäß dem Kugelverbinder **1** sind mehrere Kugeln **3** an einem aus Kunstharz hergestellten Verbindergurt **2** in einer Reihe in vorbestimmten Abständen angeordnet, und die Kugeln **3** sind in einem Zustand frei drehbar, in dem sie durch den Verbindergurt **2** gehalten werden.

[0058] Der Verbindergurt **2** ist mit vier Gurtteilen **5** versehen, die in streifenartiger Form entlang von Kugelflächen der Kugeln **3** und in Anordnungsrichtung der Kugeln **3** gebildet sind, und die Gurtteile **5** sind mit anderen Gurtteilen **5** zwischen den einander benachbarten Kugeln **3** gegenseitig verbunden. Ferner sind Verbindungsabschnitte **4** in scheibenartiger Form zwischen den einander benachbarten Kugeln **3** gebildet, die jeweiligen Gurtteile **5** sind mit anderen Gurtteilen **5** über die Verbindungsabschnitte **4** gegenseitig verbunden, und zudem dienen die Verbindungsabschnitte **4** als Abstandshalter zum Verhindern, daß die einander benachbarten Kugeln **3** miteinander in Kontakt kommen.

[0059] Gemäß Fig. 2 sind die Gurtteile **5** bezüglich der Kugelreihe nach oben, unten, links und rechts angeordnet, um die Kugelfläche der Kugel **3** in vier gleiche Teile aufzuteilen und die Bewegung der Kugel **3** in vier Richtungen so zu beschränken, daß sich die Kugel nicht aus einem Paar der angrenzenden Verbindungsabschnitte **4** löst. Weiterhin ist das Gurtteil **5** entlang der Kugelfläche der Kugel **3** gebildet, und betrachtet man den Kugelverbinder **1** insgesamt, bildet der Verbindergurt **2** die am stärksten eingeschnürte Form an der Position, an der der Verbinderabschnitt **4** gebildet ist.

[0060] Der Kugelverbinder **1** ist durch Spritzgießen von Kunstharz geformt, wobei die Kugeln **3** in einem Werkzeug als Kerne angeordnet sind, und wird gefertigt, indem der Verbindergurt **2** zusammen mit den Kugeln **3** nach Formgebungsabschluß aus dem Werkzeug entnommen wird. Wird der Verbindergurt **2** einfach durch Spritzgießen geformt, werden die Verbindungsabschnitte **4** und Gurtteile **5** des Gurts **2** in engen Kontakt mit den Kugeln **3** gebracht, und die Kugeln **3** können im Hinblick auf den Verbindergurt nicht frei drehen, weshalb gemäß dieser Ausführungsform der Kugelverbinder **1** nach Formgebungsabschluß in ein Gleitmittel aus der Gruppe der Mineralöle getaucht wird und sich Spielräume zwischen den Kugeln **3** und den Verbindungsabschnitten **4** oder Gurtteilen **5** bilden, nachdem man das allmähliche Quellen des Verbindergurts **2** abwartet, wodurch die Kugeln **3** frei drehen können.

[0061] Gemäß dem Kugelverbinder **1** dieser Ausführungsform mit dem zuvor beschriebenen Aufbau bildet der Verbindergurt **2** die am stärksten eingeschnürte Form zwischen den Kugeln **3**, d. h. die Position, an der der Verbindungsabschnitt **4** gebildet ist, weshalb der Kugelverbinder **1** an dieser Position in jeder Richtung frei verbogen werden kann, z. B. kann gemäß Fig. 2 der Kugelverbinder **1** nicht nur in Pfeillinienrichtung "a" frei verbogen werden, wo das Gurtteil **5** vorhanden ist, sondern auch in Pfeillinienrichtung "b", die zwischen den einander benachbarten Gurtteilen **5** angeordnet ist.

[0062] Wie zuvor erwähnt, ist der Kugelverbinder **1** an den Positionen, an denen die jeweiligen Verbindungsabschnitte **4** gebildet sind, eingeschnürt, weshalb auch bei Verdrehung des Kugelverbinders **1** in Pfeillinienrichtung "c" in Fig. 2 der Verbindergurt **2** der Verdrehung folgt und problemlos verformt werden kann. Auch bei Verformung des Verbindergurtes **2** durch Folgen der Verdrehung besteht keine Gefahr, daß sich die Kugeln **3** vom Verbindergurt **2** lösen, da die Bewegung der Kugeln **3** aus vier Richtungen durch die vier Abschnitte der streifenartigen Gurtteile **5** eingeschränkt ist.

Erste Ausführungsform

[0063] Fig. 3 zeigt eine erste Ausführungsform, in der der Kugelverbinder auf ein Lineargleitlager angewendet ist.

[0064] In Fig. 3 bezeichnet die Bezugszahl **10** eine Laufschiene, die an einer feststehenden Einheit, z. B. einem Bett einer Werkzeugmaschine o. ä., angeordnet ist, die Bezugszahl **20** bezeichnet einen Gleitsockel mit Kugelendloslaufbahnen, in die die Kugelverbinder **1** integriert sind und die einen beweglichen Körper, z. B. einen Tisch o. ä., entlang der Laufschiene **10** führen, und die Bezugszahl **3** bezeichnet Kugeln, die zwischen der Laufschiene **10** und dem Gleitsockel **20** rollen, während sie Last tragen und im Gleitsockel **20** endlos im Umlauf geführt werden.

[0065] Zunächst ist der Schnitt der Laufschiene **10** im wesentlichen quadratförmig, und insgesamt zwei Trassen von Kugelrollrillen **11** in Spitzbogenform sind auf ihren beiden Seitenflächen in Längsrichtung (senkrechte Richtung zur Fläche von Fig. 2) gebildet. Bolzenbefestigungslöcher **12** sind in der Laufschiene **10** in Längsrichtung mit passenden Abständen gebildet, und die Laufschiene **10** ist an der feststehenden Einheit durch nicht gezeigte Befestigungsbolzen befestigt, die in die Bolzenbefestigungslöcher **12** eingesetzt sind.

[0066] Ferner ist der Gleitsockel **20** mit einem waagerechten Abschnitt **20a**, an dem Befestigungsflächen **21** des beweglichen Körpers gebildet sind, und einem Paar Schürzenabschnitten **20b** versehen, die vom waagerechten Abschnitt **20a** herabhängen, wodurch der Schnitt im wesentlichen eine sattelartige Form hat, und den Kugelrollrillen **11** der Laufschiene **10** gegenüberliegende spitzbogenförmige Lastrollrillen **23** sind auf der Innenflächenseite der jeweiligen Schürzenabschnitte **20b** gebildet. Außerdem sind Kugelrücklauflöcher **24** entsprechend den jeweiligen Lastrollrillen **23** an den jeweiligen Schürzenabschnitten **20b** gebildet, und die Kugel **3**, die den Rollvorgang in der Lastrollrille **23** beendet hat und entlastet ist, rollt in Gegenrichtung zur Rollrichtung in der Lastrollrille **23**.

[0067] Gefertigt ist der Gleitsockel **20** durch Spritzgießen von Kunstharz. Das heißt, der Gleitsockel **20** ist gebildet, indem Harzabschnitte **22** durch Spritzgießen auf den Blockhauptkörper **25** aufgebracht werden, der aus Metall hergestellt und spanend bearbeitet ist, während mechanische Festigkeit erfordernde Abschnitte, z. B. die Befestigungsflächen **21** für den beweglichen Körper, die Lastrollrillen für die Kugeln **3** usw., am Blockhauptkörper **25** gebildet sind, und Abschnitte, in denen mechanische Festigkeit unwichtig ist, z. B. die Kugelrücklauflöcher **24** u. ä., aus Kunstharz gebildet sind, wodurch eine leichtgewichtige Struktur des Gleitsockels **20** mit möglichst geringem Gewicht erreicht ist.

[0068] Fig. 4 ist eine Schnittansicht der Kugelendloslaufbahn des Gleitsockels **20**, in die der Kugelverbinder **1** integriert ist, und die Endloslaufbahn wird fertiggestellt, indem aus Kunstharz hergestellte Deckel **30** sowohl an der Vorder- als auch an der Rückfläche des Gleitsockels **20** befestigt werden. Das heißt, bei Befestigung der Deckel **30** am Gleitteil **20** sind U-förmige Richtungsänderungswege **32** fertiggestellt, indem Kugelführungsabschnitte **26** auf der Seite des Gleitsockels **20** in U-förmige Rillen **31** auf der Seite der Deckel **30** eingefügt und die Lastrollrille **23** sowie das Kugelrücklaufloch **24** des Gleitsockels **20** durch die Richtungsänderungswege **32** verbunden sind.

[0069] Fig. 5 ist eine vergrößerte Ansicht eines Rollzustands der Kugeln in der Endloslaufbahn.

[0070] Austrittsrillen **27** sind an den tiefsten Abschnitten der Kugelrollrille **11** bzw. Lastrollrille **23** spitzbogenförmig ausgebildet, und beim Rollen der Kugeln **3** in den Rollrillen **23** und **11** sind die Gurtteile **5** des Kugelverbinders **1** in den Austrittsrillen **27** aufgenommen. Zudem sind vier Trassen von Führungsrillen **28** im Kugelrücklaufloch **24** des Gleitsockels **20** in Längsrichtung gebildet, die Gurtteile **5** des Kugelverbinders **1** in unbelastetem Zustand werden durch die Führungsrillen **28** geführt, und schlangenförmiges Bewegen des Kugelverbinders **1** im Kugelrücklaufloch **24** ist verhindert.

[0071] Wird ferner gemäß dem Lineargleitlager der Ausführungsform mit dem zuvor beschriebenen Aufbau der Gleitsockel **20** auf der Laufschiene **10** bewegt, rollen die Kugeln **3** auf den Lastrollrillen **23** des Gleitsockels **20** und auf den Kugelrollrillen **11** der Laufschiene **10**, und die Kugelverbinder **1** werden in den Endloslaufbahnen im Umlauf geführt, die im Gleitsockel **20** gebildet sind.

[0072] Gemäß dem Lineargleitlager der Ausführungsform weicht in diesem Fall gemäß Fig. 5 die Position, an der das Kugelrücklaufloch **24** im Gleitsockel **20** gebildet ist, nach oben gegenüber einer Richtung ab, in der die Kugelrollrille **11** der Laufschiene **10** und die Lastrollrille **23** des Gleitsockels **20** einander gegenüber liegen, d. h. gegenüber der Kugelkontaktrichtung, und die Richtungsänderungswege **32** zum Verbinden der Lastrollrille **23** mit dem Kugelrücklaufloch **24** sind so gebogen, daß sie von der Kugelkontaktrichtung abweichen.

[0073] Wie aber zuvor erwähnt, hat der Kugelverbinder **1** den Aufbau, durch den er sich in jeder Richtung nachgiebig leicht verbiegt, weshalb gemäß dem Lineargleitlager dieser Ausführungsform auch bei gebogenen Richtungsänderungswegen **32** gemäß Fig. 5 die Kugelverbinder **1** die Richtungsänderungswege **32** problemlos durchlaufen können und sich ein glatter Umlauf des Kugelverbinders **1** in der Endloslaufbahn erreichen läßt.

Zweite Ausführungsform

[0074] Fig. 6 zeigt eine zweite Ausführungsform, in der ein erfindungsgemäßer Kugelverbinder auf ein Lineargleitlager angewendet ist.

[0075] Während gemäß der o. g. ersten Ausführungsform eine Trasse der Kugelrollrille **11** auf jeder der beiden Seitenflächen der Laufschiene **10** gebildet ist, sind gemäß der Linearführungsvorrichtung dieser Ausführungsform zwei Trassen der Kugelrollrillen **11** auf jeder der beiden Seitenflächen der Laufschiene **10** gebildet, und der Gleitsockel **20** kann auf der Laufschiene **10** unter größerer Last als in der ersten Ausführungsform bewegt werden.

[0076] Ferner sind zwei Trassen der Lastrollrillen **23** auf der Seite jeder der Innenflächen der Schürzenabschnitte des Gleitsockels **20** gebildet, und die Kugeln **3** rollen zwischen den Lastrollrillen **23** und den Kugelrollrillen **11** der Laufschiene **10**. Alle entsprechenden Kugelrollrillen **11** und entsprechenden Lastrollrillen **23** sind spitzbogenförmig und die o. g. Austrittsrillen zur Aufnahme der Gurtteile **5** des Kugelverbinders **1** sind an den tiefsten Abschnitten der Rillen **11** und **23** ähnlich ausgebildet.

[0077] Ferner sind aus Kunstharz hergestellte Führungsabschnitte **29** auf den Seiten der Innenfläche der Schürzenabschnitte des Gleitsockels **20** angrenzend an die Lastrollrillen **23** aufgebracht, und die Führungsabschnitte **29** führen die Teile **5** der Kugelverbinder **1**, wodurch schlangenförmiges Bewegen und Verdrehen der Kugelverbinder **1** in belastetem Zustand verhindert sind. Ansonsten ähnelt der weitere Aufbau dem der o. g. ersten Ausführungsform, weshalb die gleichen Bezugszahlen in Fig. 6 vergeben sind und auf eine nähere Erläuterung verzichtet wird.

[0078] Auch in dieser Ausführungsform sind die Richtungsänderungswege zum Verbinden der Lastrollrillen **23** mit den Kugelrücklauflöchern **24** so gebogen, daß sie von den Kugelkontaktrichtungen abweichen, und als Ergebnis der Integration der Kugelverbinder **1** mit ausgezeichneter Flexibilität gemäß Fig. 1 in die Endloslaufbahnen können ähnlich wie in der o. g. ersten Ausführungsform die Kugelverbinder **1** die Richtungsänderungswege problemlos durchlaufen, und es läßt sich ein glatter Umlauf der Kugelverbinder **1** in den Endloslaufbahnen erreichen.

Dritte Ausführungsform

[0079] In Fig. 7 ist außerdem eine dritte Ausführungsform gezeigt, in der ein erfindungsgemäßer Kugelverbinder auf ein Lineargleitlager angewendet ist.

[0080] Gemäß dieser Ausführungsform sind ähnlich wie in der o. g. zweiten Ausführungsform zwei Trassen der Kugelrollrillen **11** auf jeder der beiden Seitenflächen der Laufschiene **10** gebildet, aber keine der jeweiligen Kugelrollrillen **11** ist dort spitzbogenförmig, wo sich ein Paar Kugelrollflächen schneidet, sondern kreisbogenförmig mit einer einzelnen Kugelrollfläche. Ferner ist jede der Kugelrollrillen **11** nach oben oder unten so gebildet, daß ein Winkel von 45° bezogen auf die waagerechte Richtung vorliegt.

[0081] Außerdem sind zwei Trassen der Lastrollrillen **23** in Kreisbogenform gegenüber den Kugelrollrillen der Laufschiene auf der Seite jeder der Innenflächen der Schürzenabschnitte des Gleitsockels **20** gebildet, und die Kugeln **3** rollen zwischen den Lastrollrillen **23** und den Kugelrollrillen **11** der Laufschiene **10**. Weiterhin sind im Gleitsockel **20** auch die aus Kunstharz hergestellten Führungsabschnitte **29** auf beiden Seiten der jeweiligen Lastrollrillen **23** aufgebracht, die Führungsabschnitte **29** führen die Gurtteile **5** der Kugelverbinder **1**, und schlangenförmiges Bewegen und Verdrehen der Kugelverbinder **1** in belastetem Zustand sind verhindert.

[0082] In dieser Ausführungsform ist aber zu befürchten, daß beim Rollen der Kugeln in den Lastrollrillen **23** des Gleitsokkels **20** und in den Kugelrollrillen **11** der Laufschiene **10** die Gurtteile **5** der Kugelverbinder **1** mit den Lastrollrillen **23** und den Kugelrollrillen **11** in Kontakt kommen können, weshalb die vier Gurtteile **5** zum Umfassen der Kugel **3** nicht so angeordnet sind, daß sie die Kugelfläche der Kugel **3** gleichmäßig vierteilen, sondern die vier Gurtteile **5** so abweichend angeordnet sind, daß der Abstand zwischen zwei Gurtteilen **5**, die auf beiden Seiten jeder der Lastrollrillen **23** und Kugelrollrillen **11** angeordnet sind, verbreitert ist. Im übrigen ähnelt der Aufbau dem der o. g. ersten Ausführungsform, weshalb die gleichen Bezugszahlen in Fig. 7 verwendet werden und auf eine nähere Beschreibung verzichtet wird.

[0083] Die Lastrollrillen **23** sind nach unten oder oben in einem Winkel von 45° bezogen auf die waagerechte Richtung gebildet, weshalb im Hinblick auf den glatten Umlauf der Kugeln **3** die Kugelrücklauflöcher **24** einen Winkel von 45° nach oben oder 45° nach unten zur jeweiligen Lastrollrille **23** aufweisen müssen. Sind aber die Kugelrücklauflöcher **24** an solchen Positionen gebildet, ist zu befürchten, daß der Abstand zwischen den Kugelrücklauflöchern **24**, die in Auf- und Abwärtsrichtung aneinandergrenzen, steigt und daß der Gleitsockel vergrößert ist, weshalb gemäß dieser Ausführungsform die jeweiligen Kugelrücklauflöcher **24** in waagerechter Richtung der jeweiligen Lastrollrillen **23** aneinandergrenzend gebildet sind, indem die Richtungsänderungswege **32** gebogen sind.

[0084] Auch bei Bildung der Kugelrücklauflöcher **24** an diesen Positionen können gemäß der Linearführungsvorrichtung dieser Ausführungsform als Ergebnis der Integration der Kugelverbinder gemäß Fig. 1 in die Endloslaufbahnen die Kugelverbinder **1** die Richtungsänderungswege **32** problemlos durchlaufen, und es läßt sich ein glatter Umlauf der Kugelverbinder **1** in den Endloslaufbahnen erreichen.

Vierte Ausführungsform

[0085] Fig. 8 zeigt eine vierte Ausführungsform, in der ein erfindungsgemäßer Kugelverbinder auf ein Lineargleitlager angewendet ist.

[0086] Die Ausführungsform zeigt eine Linearführungsvorrichtung, in der die Positionen, an denen die Kugelrollrillen **11** gebildet sind, bezüglich der Führungsschiene **10** gegenüber denen in der dritten Ausführungsform geändert sind und zwei Trassen der Kugelrollrillen **11** auf der Oberseite der Laufschiene **10** gebildet sind, während eine Trasse der Kugelrollrille **11** auf jeder der beiden in einem Winkel von 30° nach unten weisenden Seitenflächen gebildet ist.

[0087] Ferner sind die Lastrollrillen **23** im Gleitsockel **20** an Positionen gegenüber den Kugelrollrillen **11** der Laufschiene **10** gebildet, und die an den Kugelverbindern **1** angeordneten Kugeln **3** rollen zwischen den Kugelrollrillen **11** und Lastrollrillen **23**, während sie Last tragen. Ansonsten ähnelt der übrige Aufbau dem der dritten Ausführungsform, weshalb in Fig. 8 die gleichen Bezugszahlen vergeben sind und auf eine nähere Beschreibung verzichtet wird.

[0088] Gemäß der Linearführungsvorrichtung der vierten Ausführungsform sind die nach unten gerichteten Lastrollrillen **23** am waagerechten Abschnitt **20a** des Gleitsockels **20** gebildet, weshalb unter der Annahme, daß die Kugelrücklauflöcher **24** entsprechend den Lastrollrillen **23** in Kugelkontaktrichtung gebildet sind, der waagerechte Abschnitt **20a** des Gleitsockels **20** verdickt sein muß, um der Länge der Richtungsänderungswege Rechnung zu tragen, wobei aber gemäß dieser Ausführungsform in Fig. 8 die Positionen, an denen die Kugelrücklauflöcher **24** gebildet sind, gegenüber den Kugelkontaktrichtungen verschoben sind und die Richtungsänderungswege **32** von den Lastrollrillen **23** zu den Kugelrücklauflöchern **24** gebogen sind, weshalb auch bei dünner Bildung des waagerechten Abschnitts **20a** des Gleitsockels **20** die Längen der Richtungsänderungswege **32** erreicht werden können, und die Wenderadien der Kugeln **3** können aufgrund dieser Beträge groß sein.

[0089] Auch bei gebogenen Richtungsänderungswegen **32** können gemäß der Linearführungsvorrichtung dieser Ausführungsform als Ergebnis der Integration der Kugelverbinder **1** gemäß Fig. 1 in die Endloslaufbahnen die Kugelverbinder **1** die Richtungsänderungswege **32** problemlos durchlaufen, und ein glatter Umlauf der Kugelverbinder **1** in den Endloslaufbahnen läßt sich erreichen.

Fünfte Ausführungsform

[0090] Als nächstes zeigen Fig. 9 und Fig. 10 eine fünfte Ausführungsform, in der ein erfindungsgemäßer Kugelverbinder auf eine Kugelkeilvorrichtung angewendet ist.

[0091] In den Zeichnungen bezeichnet die Bezugszahl **50** eine Keilwelle, in der Kugelrollrillen gebildet sind, die Bezugszahl **60** bezeichnet ein Mutternteil, das Kugelendloslaufbahnen aufweist, in die die Kugelverbinder **1** integriert sind und das auf den Außenumfang der Keilwelle **50** aufgepaßt ist, und die Bezugszahl **3** bezeichnet Kugeln, die zwischen der Keilwelle **50** und dem Mutternteil **60** rollen, während sie Last tragen und im Inneren des Mutternteils **60** endlos im Umlauf geführt werden.

[0092] Zunächst ist die Keilwelle **50** im wesentlichen zylinderförmig, und vorstehende Trassen **51** in Axialrichtung (senkrechte Richtung zur Fläche von Fig. 9) sind auf ihrer Außenumfangsfläche gebildet. Die vorstehenden Trassen **51** sind an drei Stellen in Umfangsrichtung der Keilwelle **50** in gleichmäßigen Abständen angeordnet, und Kugelrollrillen **52** in Kreisbogenform sind jeweils auf beiden Seitenflächen jedes der vorstehenden Trassen **51** gebildet.

[0093] Ferner ist das Mutternteil **60** zylinderförmig und auf seiner Außenumfangsfläche mit einer Keilnut **61** zum Befestigen des Mutternteils **60** an einem beweglichen Körper versehen, und außerdem sind Lastrollrillen **62** auf seiner Innenumfangsfläche in Kreisbogenform gegenüber den Kugelrollrillen **52** der Keilwelle **50** gebildet. Insgesamt drei Sätze der Lastrollrillen **62** sind gebildet, wobei ein Paar aneinandergrenzender Lastrollrillen **62** einen Satz darstellt, und die vorstehende Trasse **51** der Keilwelle **50** ist zwischen dem Paar Lastrollrillen **62** angeordnet, die für jeden Satz vorgesehen sind.

[0094] Zudem ist ein Kugelrücklaufloch **63** entsprechend jeder der Lastrollrillen **62** in der Umgebung der Innenumfangsfläche des Mutternteils **60** gebildet, und die Kugel **3**, die das Rollen auf der Lastrollrille **62** beendet hat und entlastet ist, rollt in Gegenrichtung zu der Richtung, in der sie in der Lastrollrille **62** gerollt ist. Vier Trassen von Führungsrillen **64** sind im Kugelrücklaufloch **63** in Längsrichtung gebildet, die Gurtteile **5** des Kugelverbinders **1** in unbelastetem Zustand werden durch die Führungsrillen **64** geführt, und schlangenförmiges Bewegen des Kugelverbinders **1** im Inneren des Kugelrücklauflochs **63** ist verhindert.

[0095] Weiterhin sind Kugelführungsabschnitte **65** auf der Innenumfangsfläche des Mutternteils **60** angrenzend an die Lastrollrillen **62** gebildet, und die Gurtteile **5** des Kugelverbinders **1** werden in belastetem Zustand zwischen dem Mutternteil **60** und der Keilwelle **50** so geführt, daß sie in Gleitkontakt mit den Kugelführungsabschnitten **65** gebracht sind.

[0096] Das Mutternteil **60** ist durch Spritzgießen von Kunstharz hergestellt. Das heißt, das Mutternteil **60** wird gebildet, indem ein Harzabschnitt **67** durch Spritzgießen auf die Innenumfangsfläche eines Mutternhauptkörper **66** aufgebracht wird, der aus Metall hergestellt und spanend bearbeitet ist, während mechanische Festigkeit erfordernde Abschnitte, z. B. die o. g. Keilnut **61**, die Lastrollrillen **62** u. ä., am Mutternhauptkörper **66** gebildet sind, und Abschnitte, an denen mechanische Festigkeit unwichtig ist, z. B. die Kugelrücklauflöcher **63**, die Kugelführungsabschnitte **65** usw., durch Kunstharz gebildet sind, wodurch ein leichtgewichtiger Aufbau des Mutternteils **60** mit möglichst geringem Gewicht erreicht wird.

[0097] Die Kugelverbinder **1** sind in die Kugelendloslaufbahnen des Mutternteils **60** integriert, und die Kugelendlosbahnen werden fertiggestellt, indem aus Kunstharz hergestellte Dekkel **80** sowohl auf die vordere als auch hintere Endfläche des Mutternteils aufgepaßt werden. Sind also gemäß Fig. 10 die Deckel **80** am Mutternteil **60** befestigt, so sind die Lastrollrillen **62** und die Kugelrücklauflöcher **63** durch Richtungsänderungswege **81** in U-Form verbunden, die an den Deckeln **80** gebildet sind, wodurch die Kugelendloslaufbahn fertiggestellt ist, die die Kugeln durch die Lastrollrille **62**, den Kugelrichtungsänderungsweg **81**, das Kugelrücklaufloch **63**, den Kugelrichtungsänderungsweg **81** und die Lastrollrille **62** im Umlauf führt.

[0098] Wird gemäß der Kugelkeilvorrichtung dieser Ausführungsform mit dem o. g. Aufbau das Mutternteil **60** auf der Keilwelle **50** bewegt, rollen die Kugeln **3** auf den Lastrollrillen **62** des Mutternteils und den Kugelrollrillen **52** der Keilwelle **50**, und die Kugelverbinder **1** werden in den im Mutternteil **60** gebildeten Endloslaufbahnen im Umlauf geführt.

[0099] Um in diesem Fall gemäß der Kugelkeilvorrichtung dieser Ausführungsform eine Vergrößerung des Mutternteils zu verhindern, ist die Position, an der das Kugelrücklaufloch **63** gebildet wird, als Teil der Kugelendloslaufbahn in der Umgebung der Innenumfangsfläche des Mutternteils angeordnet und nicht in einer Richtung angeordnet, in der die Kugelrollrille **52** der Keilwelle **50** und die Lastrollrille **62** des Mutternteils **60** einander gegenüber liegen, d. h. in Kugelkontaktrichtung. Das heißt, auch in dieser Ausführungsform sind die Richtungsänderungswege **81** der Deckel **80** zum Verbinden der Lastrollrillen **62** mit den Kugelrücklauflöchern **63** so gebildet, daß sie von den Kugelkontaktrichtungen abweichen.

[0100] Gleichwohl hat der Kugelverbinder **1** einen solchen Aufbau, daß er beschreibungsgemäß in jeder Richtung nachgiebig leicht zu verbiegen ist, weshalb er gemäß der Kugelkeilvorrichtung dieser Ausführungsform auch bei Biegung der Richtungsänderungswege **81** die Richtungsänderungswege **81** problemlos durchlaufen kann und sich ein glatter Umlauf des Kugelverbinders **1** in der Endloslaufbahn erreichen läßt.

Sechste Ausführungsform

[0101] Fig. 11 zeigt eine sechste Ausführungsform einer Kugelspindelvorrichtung, auf die der Kugelverbinder angewendet ist.

[0102] In der Zeichnung bezeichnet die Bezugszahl **110** einen Spindelschaft, in dem eine Kugelrollrille **111** in Spiralform mit vorbestimmter Steigung gebildet ist, die Bezugszahl **120** bezeichnet ein Mutternteil mit einer Endloslaufbahn, in die der Kugelverbinder **1** integriert ist und das im Eingriff mit dem Spindelschaft **110** steht, und das Mutternteil **120** wird in Axialrichtung des Spindelschafts **110** durch Relativdrehung zwischen dem Spindelschaft **110** und Mutternteil **120** bewegt. Ferner sind gemäß der Kugelspindelvorrichtung zwei Trassen von Kugelrollrillen **111** am Spindelschaft **110** gebildet, und das Mutternteil **120** ist auch mit zwei Endloslaufbahnen versehen, in die die Kugelverbinder **1** integriert sind.

[0103] In diesem Fall ist das Mutternteil **120** durch einen aus Stahl hergestellten Mutternhauptkörper **121** und ein Paar aus Kunstharz hergestellte Deckel **130** gebildet, die sowohl an der vorderen als auch hinteren Endfläche des Mutternhauptkörpers **121** befestigt sind, und die Endloslaufbahnen der Kugeln **3** sind durch Befestigen der Deckel **130** am Mutternhauptkörper **121** komplettiert.

[0104] Gemäß Fig. 12 und Fig. 13 ist der Mutternhauptkörper **121** zylinderförmig mit einem Durchgangsloch **122** des Spindelschafts **110** in seiner Mitte, und ein Flanschabschnitt **123** zum Befestigen des Mutternhauptkörpers **121** an einem beweglichen Körper, z. B. einem Tisch o. ä., steht von seiner Außenumfangsfläche vor. Ferner sind Lastrollrillen **124**, die den Kugelrollrillen **111** des Spindelschafts **110** gegenüber liegen, in der Innenumfangsfläche des Durchgangslochs **122** spiralförmig gebildet und die lasttragenden Kugeln **3** rollen zwischen den Kugelrollrillen **111** und Lastrollrillen **124**. Die Lastrollrille **124** weist eine sogenannte Spitzbogenform dort auf, wo sich zwei Kugelrollflächen schneiden, und eine Austrittsrille **125** zum Aufnehmen der Gurtteile **5** des Kugelver-binders **1** ist am tiefsten Abschnitt der Rille gebildet.

[0105] Ferner sind zwei Kugelrücklauflöcher **126** im Mutternhauptkörper **121** in Axialrichtung vorgesehen. Vier Trassen von Führungsnuten **126a** zum Führen der Gurtteile **5** des Kugelversbinders **1** sind am Innendurchmesser des Kugelrücklauflochs **126** in Längsrichtung gebildet, und zudem sind Aussparungsabschnitte **126b** an seinen beiden Endöffnungsabschnitten zum Einpassen von Positioniervorsprüngen später erwähnter Rücklaufstücke **131** gebildet. Im übrigen bezeichnet in Fig. 12 die Bezugszahl **127** Bolzenbefestigungslöcher, die sich am Flanschabschnitt **123** öffnen, und die Bezugszahl **128** bezeichnet Gewindelöcher, in die Schrauben zum Befestigen der Deckel **130** eingeschraubt werden.

[0106] Die an den beiden Enden des Mutternhauptkörpers **121** befestigten jeweiligen Deckel **130** sind durch ein Paar der Rücklaufstücke **131** mit Richtungsänderungswegen **140** zum Verbinden der Lastrollrillen **124** des Mutternhauptkörpers **121** mit den Kugelrücklauflöchern **126** sowie durch Abdeckteile **132** gebildet, die an Endabschnitten des Mutternhauptkörpers **121** in einem Zustand befestigt sind, in dem die Rücklaufstücke **131** gehalten werden.

[0107] Gemäß Fig. 14 und Fig. 15 ist im Abdeckteil **132** ein Durchgangsloch **133** entsprechend dem Durchgangsloch **122** des Mutternhauptkörpers gebildet, und im wesentlichen fächerförmige Aussparungsabschnitte **134** zum Aufnehmen der Rücklaufstücke sind an zwei Stellen gebildet, zwischen denen das Durchgangsloch **133** eingefügt ist. Ferner sind auf der Innenumfangsfläche des Durchgangslochs **133** Eintrittswege **135** zum Führen der Kugeln **3** gebildet, die aus den Lastrollrillen **124** des Mutternhauptkörpers **121** in die Richtungsänderungswege **140** des Rücklaufstücks **131** rollen, und Führungsrillen **136** zum Führen der Gurtteile **5** der Kugelverbinder **1** sind auch in den Eintrittswegen **135** gebildet. Im übrigen bezeichnet die Bezugszahl **137** in Fig. 14 Befestigungslöcher zum Befestigen von Schrauben, die mit dem Mutternhauptkörper **121** verschraubt sind.

[0108] Ferner ist gemäß Fig. 16 und Fig. 17 das auf den Aussparungsabschnitt **134** des Abdeckteils **132** aufgepaßte Rücklaufstück **131** durch ein Paar aus einem ersten Stück **131a** und einem zweiten Stück **131b** gebildet, die auf den Aussparungsabschnitt **134** in gegenseitiger Überdeckung aufgepaßt sind, und der Richtungsänderungsweg **140** ist durch Überdecken der Stücke **131a** und **131b** fertiggestellt. Die jeweiligen Stücke **131a** und **131b** sind durch Spritzgießen von Kunstharz hergestellt, ausgesparte Trassenrillen **140a** und **140b** mit einem im wesentlichen halbkreisförmigen Schnitt, die durch Zweiteilen des Richtungsänderungswegs **140** in Längsrichtung erzeugt sind, sind auf der Oberfläche des ersten Stücks **131a** bzw. der Rückfläche des zweiten Stücks **131b** gebildet, und ferner sind Führungsnuten **141a** und **141b** zum Führen der Gurtteile **5** des Kugelverbinders **1** an den ausgesparten Trassenrillen **140a** bzw. **140b** ähnlich gebildet.

[0109] Gemäß Fig. 16 erstreckt sich auf der Innendurchmesserseite des Rücklaufstücks **131** der Richtungsänderungsweg **140** in Tangentialrichtung des Durchgangslochs **133** des Abdeckteils **132**, während gemäß Fig. 17 auf der Außendurchmesserseite der Richtungsänderungsweg **140** zur Oberflächenseite des zweiten Stücks **131b** ansteigt. Dadurch wird die Kugel **3**, die die Rollbewegung in der Lastrollrille **124** des Mutternhauptkörpers **121** beendet hat, in den Richtungsänderungsweg **140** über den Eintrittsweg **135** des Abdeckteils **132** glatt eingeführt, während sich die Rollrichtung von der Radialrichtung zur Axialrichtung des Mutternteils **120** ändert, und die Kugel **3** wird störungsfrei zum Kugelrücklaufloch **126** des Mutternhauptkörpers **121** transportiert.

[0110] Ferner stehen Vorsprungstücke **142a** und **142b** in Halbkreisform auf Oberflächen der jeweiligen Stücke **131a** und **131b** entsprechend dem Richtungsänderungsweg **140** vor, und bei Überdeckung des ersten Stücks **131a** und zweiten Stücks **131b** kombinieren sich die Vorsprungstücke **142a** und **142b**, wodurch der Positioniervorsprung **142** des Rücklaufstücks **131** an einem Endabschnitt des Richtungsänderungswegs **140** gebildet ist.

[0111] Weiterhin sind die Stücke **131a** und **131b** am Aussparungsabschnitt **134** des Abdeckteils **132** in einer Reihenfolge vom ersten Stück **130a** aufgepaßt, und das Abdeckteil **132** ist am Mutternhauptkörper **121** so befestigt, daß das zweite Stück **131b** mit dem Mutternhauptkörper **121** in Kontakt steht, wodurch die Befestigung des Deckels **130** am Mutternhauptkörper **121** abgeschlossen ist. Dadurch sind gemäß Fig. 18 die Lastrollrille **124** des Mutternhauptkörpers **121** und das Kugelrücklaufloch **126** durch den Richtungsänderungsweg **140** verbunden, und die Endloslaufbahn der Kugeln **3** ist im Mutternteil **120** gebildet. In diesem Fall ist durch Aufpassen des am Rücklaufstück **131** gebildeten Positioniervorsprungs **142** auf den am Endabschnitt des Kugelrücklauflochs **126** des Mutternhauptkörpers **121** gebildeten Aussparungsabschnitt **126b** die Positionsbeziehung zwischen dem Mutternhauptkörper **121** und dem Deckel **130** ordnungsgemäß hergestellt, und ein glattes Rollen der Kugeln **3** zwischen dem Kugelrücklaufloch **126** und dem Richtungsänderungsweg **140** ist gewährleistet. Im übrigen zeigt Fig. 18 in Perspektive den am Mutternhauptkörper **121** angeordneten Deckel **130** aus der Axialrichtung des Spindelschafts **110**.

[0112] Dreht gemäß der Kugelspindelvorrichtung der Ausführungsform mit dem zuvor beschriebenen Aufbau der Spindelschaft **110** relativ zum Mutternteil **120**, rollen die in den Kugelverbinder **1** integrierten Kugeln **3** in der Lastrollrille **124** des Mutternteils **120** und Kugelrollrille **111** des Spindelschafts **110**, und der Kugelverbinder **1** wird in der im Mutternteil **120** gebildeten Endloslaufbahn im Umlauf geführt.

[0113] Gemäß der Kugelspindelvorrichtung dieser Ausführungsform ist in diesem Fall der Kugelverbinder **1** spiralförmig um den Außenumfang des Spindelschafts **110** gewickelt, weshalb der Kugelverbinder **1** in der Endlosbahn begleitet von Verdrehung im Umlauf geführt wird. Da aber der Kugelverbinder **1** dieser Ausführungsform den Aufbau hat, bei dem er sich beschreibungsgemäß in jeder Richtung nachgiebig leicht verbiegen und leicht verdrehen läßt, kann der Kugelverbinder **1** in der Endloslaufbahn des Mutternteils **120** problemlos im Umlauf geführt werden, und eine glatte Umlaufführung des Kugelverbinders **1** in der Endlosbahn läßt sich erreichen.

[0114] Auch bei häufigem Verbiegen oder Verdrehen des Kugelverbinders **1** sind gemäß dem Kugelverbinder **1** dieser Ausführungsform die Kugeln **3** durch den Verbindergurt **2** vollständig umschlossen, weshalb sich die Kugeln **3** nicht vom Kugelverbinder **1** lösen und unbeabsichtigtes Trennen der Kugeln **3** von der Endloslaufbahn von vornherein verhindert werden kann.

Siebente Ausführungsform

[0115] Fig. 19 zeigt eine siebente Ausführungsform, in der ein erfindungsgemäßer Kugelverbinder auf eine Kugelspindelvorrichtung angewendet ist.

[0116] Während gemäß der o. g. sechsten Ausführungsform die Endloslaufbahnen der Kugeln mit Hilfe der Deckel gebildet sind, die sowohl an der vorderen als auch hinteren Endfläche des Mutternhauptkörpers befestigt sind, und die Kugelverbinder gemäß Fig. 1 in die Endloslaufbahnen integriert sind, ist gemäß dieser Ausführungsform eine Kugelendloslaufbahn durch ein Rücklaufrohr gebildet, das an einem Mutternteil befestigt ist, und der gleiche Kugelverbinder **1** wie in der sechsten Ausführungsform ist in die Endloslaufbahn integriert.

[0117] In der Zeichnung bezeichnet die Bezugszahl **150** einen Spindelschaft, in dem eine Kugelrollrille **151** in Spiralform gebildet ist, die Bezugszahl **152** bezeichnet ein Mutternteil, in dem eine Lastrollrille **153** gegenüber der o. g. Kugelrollrille **151** gebildet ist, und die Bezugszahl **154** bezeichnet ein Rücklaufrohr, das am Mutternteil **152** befestigt ist. Das Rücklaufrohr ist am Mutternteil **152** so befestigt, daß mehrere Windungen der Kugelrollrille **151** des Spindelschafts übersprungen werden, und die Kugeln **3** werden durch einen Endabschnitt des Rücklaufrohrs **154** aus der Kugelrollrille **151** des Spindelschafts **150** nach oben geführt, rollen im Rücklaufrohr **154** und werden in die Kugelrollrille **151** unter Überspringen mehrerer Windungen in Vorwärtsrichtung übergeben, wodurch die Kugeln **3** im Mutternteil **152** endlos umlaufen.

[0118] Gemäß **Fig.** 20(a) und 20(b) ist das Rücklaufrohr **154** durch Kombinieren eines Paars Rohrhälften **155** gebildet, deren Schnitt jeweils im wesentlichen halbkreisförmig ist, und die jeweiligen Rohrhälften **155** sind durch Spritzgießen von Kunstharz hergestellt. Ferner ist eine ausgesparte Trassenrille **156**, die einen Kugelrücklaufweg bildet, an jeder der Rohrhälften **155** gebildet, während Führungsrillen **157** zum Führen der Gurtteile **5** des Kugelverbinders **1** an der ausgesparten Trassenrille **156** gebildet sind.

[0119] Auch bei der Kugelspindelvorrichtung gemäß der Ausführungsform mit dem zuvor beschriebenen Aufbau hat der in die Endloslaufbahn des Mutternteils **152** integrierte Kugelverbinder **1** einen Aufbau, bei dem er in jeder Richtung nachgiebig leicht zu verbiegen und leicht zu verdrehen ist, weshalb er in der Endloslaufbahn des Mutternteils **152** problemlos im Umlauf geführt werden kann und sich eine glatte Umlaufführung des Kugelverbinders **1** in der Endloslaufbahn erreichen läßt.

[0120] Ferner wird der Kugelverbinder **1** in der Endloslaufbahn in einem Zustand im Kreislauf geführt, in dem die Gurtteile **5** in die Führungsrillen **157** des Rücklaufrohrs **154** eingepaßt sind, weshalb bei Annäherung der Kugeln **3** an das Rücklaufrohr **154** diese in das Rücklaufrohr **154** gezogen werden, indem sie durch den Verbindergurt **2** gezogen werden, der den Kugelverbinder **1** bildet, so daß die Kugeln **3** glatt in das Rücklaufrohr **154** ein- und aus ihm austreten können und der Umlauf der Kugeln **3** in der Endloslaufbahn dadurch auch glatt durchgeführt werden kann.

Achte Ausführungsform

[0121] Als nächstes zeigt Fig. 21 eine achte Ausführungsform, in der der erfindungsgemäße Kugelverbinder auf eine Kugelspindelvorrichtung angewendet ist.

[0122] Gemäß der achten Ausführungsform ist anstelle des Rücklaufrohrs **154**, das in der o. g. siebenten Ausführungsform zum Einsatz kommt, ein Ablenker **160** am Mutternteil **152** befestigt, die Endloslaufbahn der Kugeln **3** ist mit Hilfe des Ablenkers **160** gebildet, und der zuvor beschriebene Kugelverbinder **1** ist in die Endloslaufbahn integriert. Ansonsten ähnelt der Aufbau dem in der zuvor beschriebenen siebenten Ausführungsform, weshalb in Fig. 21 die gleichen Bezugszahlen verwendet werden und auf eine nähere Beschreibung verzichtet wird.

[0123] Gemäß Fig. 21 ist der Ablenker **160** am Mutternteil **152** so befestigt, daß eine Windung der Kugelrollrille **151** des Spindelschafts **150** übersprungen wird, der Laufweg der aus der Kugelrollrille **151** rollenden Kugeln **3** wird durch den Ablenker **160** geändert, und die Kugeln **3** werden zu den Kugelrollrillen **151** unter Überspringen einer Windung in Vorwärtsrichtung zurückgeführt, indem sie über den Außendurchmesser des Spindelschafts **150** laufen, wodurch die Kugeln **3** im Mutternteil **152** endlos umlaufen. Ferner sind drei Ablenker **160** am Mutternteil **152** in dieser Ausführungsform befestigt, um den Umfang des Mutternteils **152** dreizuteilen, und insgesamt drei Endloslaufbahnen der Kugeln **3** sind gebildet. Somit sind drei Kugelverbinder **1** in das Mutternteil **152** integriert.

[0124] Fig. 22 bis Fig. 24 zeigen einen näheren Aufbau des Ablenkers **160**.

[0125] Eine im wesentlichen S-trassenförmige Kugelrücklaufrille **161** ist im Ablenker **160** gebildet, und Führungsrillen **162** zum Führen der Gurtteile **5** des Kugelverbinders **1** sind in der Mitte und an beiden Seiten der Kugelrücklaufrille **161** gebildet. Ferner hat die Kugelrücklaufrille **161** eine Form, bei der sie am Mittelabschnitt des Ablenkers **160** am stärksten vertieft ist, so daß die in die Kugelrücklaufrille **161** rollenden Kugeln **3** über den Außendurchmesser des Spindelschafts **150** laufen können.

[0126] Auch in der Kugelspindelvorrichtung gemäß der Ausführungsform mit dem zuvor beschriebenen Aufbau hat der Kugelverbinder **1** so einen Aufbau, daß der in die Endloslaufbahn des Mutternteils **152** integrierte Kugelverbinder **1** in jeder Richtung nachgiebig leicht zu verbiegen und leicht zu verdrehen ist, weshalb der Kugelverbinder **1** in der Endloslaufbahn des Mutternteils **152** problemlos im Umlauf geführt werden kann und sich ein glatter Umlauf des Kugelverbinders **1** in der Endloslaufbahn erreichen läßt.

[0127] Ferner läuft der Kugelverbinder **1** auch in dieser Ausführungsform in der Endloslaufbahn in einem Zustand um, in dem die Gurtteile **5** in die Führungsrillen **161** des Ablenkers **160** eingepaßt sind, weshalb bei Annäherung der Kugeln **3** an den Ablenker **160** diese in den Ablenker **160** aus der Kugelrollrille **151** des Spindelschafts **150** gezogen werden, indem sie durch den Verbindergurt **2** gezogen werden, weshalb die Bewegung der Kugeln **3** bei ihrem Lauf über den Außendurchmesser des Spindelschafts **150** glatt erfolgt und der Umlauf der Kugeln **3** in der Endloslaufbahn dadurch auch glatt durchgeführt werden kann.

Gewerbliche Anwendbarkeit

[0128] Wie zuvor erläutert, hat der erfindungsgemäße Kugelverbinder so einen Aufbau, daß der Verbindergurt so geformt ist, daß er zwischen den einander benachbarten Kugeln eingeschnürt ist, in jeder Richtung nachgiebig leicht zu verbiegen ist und die auf den Kugelverbinder wirkende Verdrehungen leicht aufnehmen kann, weshalb er bei Integration des Kugelverbinders in eine Kugelendloslaufbahn einer Linearführungsvorrichtung, einer Kugelspindelvorrichtung o. ä. frei verbogen oder verdreht werden kann und er sich auch in einem solchen Verwendungszustand in der Endloslaufbahn glatt im Umlauf führen läßt.

[0129] Gemäß dem Kugelverbinder der Erfindung befinden sich ferner die in ihn integrierten Kugeln in einem Zustand, in dem sie durch den Verbindergurt vollständig umfaßt sind, und auch bei erheblicher Verbiegung oder Verdrehung des Kugelverbinders lösen sich die Kugeln nicht vom Verbindergurt, weshalb durch Integrieren des Kugelverbinders in die Kugelendloslaufbahn einer Linearführungsvorrichtung, einer Kugelspindelvorrichtung o. ä., ohne Verwendung eines Kugelkäfigs verhindert werden kann, daß sich die Kugeln aus der Endloslaufbahn lösen.

Patentansprüche

1. Kugelverbinder (**1**) mit mehreren Kugeln (**3**), die in einer Reihe mit vorbestimmten Abständen angeordnet sind, und einem flexiblen Verbindergurt (**2**) zum drehbaren Halten der Kugeln und gegenseitigen Verbinden der einander benachbarten Kugeln, wobei der Verbindergurt aufweist:
vier Gurtteile (**5**), die in streifenartiger Form entlang von Umfangsflächen der Kugeln gebildet und mit den mehreren Kugeln in Kontakt gebracht sind; und
wobei die Gurtteile mit anderen Gurtteilen an Zwischenstellen der einander benachbarten Kugeln miteinander verbunden sind und der Verbindergurt in einer Form ausgebildet ist, die im Vergleich zum Außendurchmesser der Kugeln an Positionen der die Kugeln verbindenden Zwischenstellen eingeschnürt ist.

2. Kugelverbinder (**1**) nach Anspruch 1, wobei der Verbindergurt (**2**) mit den Gurtteilen (**5**) so angeordnet ist, daß die Kugelfläche jeder Kugel viergeteilt ist.

3. Linearführungsvorrichtung mit dem Kugelverbinder (**1**) nach Anspruch 1, wobei die Linearführungsvorrichtung aufweist:
einen Führungsschaft (**10**) mit Kugelrollrillen (**11**) zum Abrollen von Kugeln (**3**) in Längsrichtung;
ein Gleitteil (**20**) mit Lastrollrillen (**23**) zum Abrollen der lasttragenden Kugeln zwischen dem Führungsschaft und den Lastrollrillen, das Endloslaufbahnen zum Umlauf der Kugeln hat und entlang dem Führungsschaft entsprechend dem Umlauf der Kugeln bewegt wird; und
wobei der Kugelverbinder (**1**) nach Anspruch 1 in eine der Endloslaufbahnen integriert ist und der Kugelverbinder entsprechend einer Relativbewegung zwischen dem Führungsschaft und dem Gleitteil in der Endloslaufbahn im Umlauf geführt wird.

4. Linearführungsvorrichtung nach Anspruch 3, wobei jede der Kugelrollrillen (**11**) des Führungsschafts (**10**) und der Lastrollrillen (**23**) des Gleitteils (**20**) mit einem spitzbogenförmigen Abschnitt versehen ist, wo sich ein Paar Kugelrollflächen schneidet, und Austrittsrillen zum Aufnehmen und Führen von Verbindungsabschnitten (**4**) des Kugelverbinders an einem tiefsten Abschnitt jeder Kugelrollrille (**11**) und Lastrollrille (**23**) spitzbogenförmig ausgebildet sind.

5. Linearführungsvorrichtung nach Anspruch 3, wobei jede der Kugelrollrillen (**11**) des Führungsschafts (**10**) und der Lastrollrillen (**23**) des Gleitteils (**20**) mit einem kreisbogenförmigen Abschnitt versehen ist und eine einzige Kugelrollfläche aufweist.

6. Kugelspindelvorrichtung mit dem Kugelverbinder (**1**) nach Anspruch 1, wobei die Kugelspindelvorrichtung aufweist:
einen Spindelschaft (**50**) mit Kugelrollrillen in Spiralform zum Abrollen von Kugeln (**3**) an einer Außenumfangsfläche davon;
ein Mutternteil (**60**) mit Lastrollrillen (**62**) in Spiralform zum Abrollen der lasttragenden Kugeln zwischen dem Spindelschaft und den Lastrollrillen (**62**), das Endloslaufbahnen zum Umlauf der Kugeln hat und auf den Spindelschaft über die Kugeln aufgeschraubt ist; und
wobei der Kugelverbinder (**1**) nach Anspruch 1 in eine der Endloslaufbahnen integriert ist und der Kugelverbinder (**1**) entsprechend einer Relativbewegung zwischen dem Spindelschaft und dem Mutternteil in der Endloslaufbahn im Umlauf geführt wird.

(54) Bezeichnung: **Trennkörper für die Wälzelemente von Wälzelementführungen**

Beschreibung

[0001] Diese Erfindung bezieht sich auf Wälzelement-Abstandsteile für verschiedene Typen von Wälzführungseinheiten, wie beispielsweise eine lineare Führungseinheit, eine Kugelspindeleinheit, und dergleichen, versehen mit einem endlosen Zirkulationsdurchgangsweg für Wälzelemente, wie beispielsweise Kugeln und Rollen, wobei die Wälzelement-Abstandsteile so angepasst sind, um zwischen benachbarten Wälzelementen in dem endlosen Zirkulationsdurchgangsweg angeordnet zu werden, um die Abrasion und die Erzeugung von Wärme der Wälzelemente zu verringern und das Laufen der Wälzelemente zu beruhigen.

[0002] Die bekannten Wälzführungseinheiten, in denen ein Paar von Elementen relative Bewegungen kontinuierlich über eine Reihe von endlos zirkulierenden Kugeln oder Rollen vornimmt, umfassen eine lineare Führungseinheit, verwendet in einem linearen Führungsbereich eines Maschinenwerkzeugs und einer Überführungsvorrichtung, und so angepasst, um ein bewegbares Element, wie beispielsweise einen Tisch auf einen fixierten Bereich, wie beispielsweise einem Bett oder einem Auflageschuh, zu führen; und eine Kugelumlaufspindel, verwendet in Verbindung mit dieser linearen Führungseinheit und so angepasst, um Hübe von linearen Bewegungen auf das bewegbare Element entsprechend einem Drehumfang eines Motors aufzubringen.

[0003] Die erste erwähnte, lineare Führungseinheit umfasst eine Laufschiene, die an einem solchen fixierten Bereich, wie er vorstehend erwähnt ist, vorgesehen ist und Rollflächen besitzt, die sich in der Längsrichtung, für die Wälzelemente, erstrecken; und einen Gleitblock, der Lastwälzflächen gegenüberliegend zu den Wälzflächen der Laufschiene über eine Mehrzahl von Wälzelementen besitzt, und der mit endlosen Zirkulationsdurchgangswegen für die Wälzelemente, die auf diesen Lastwälzflächen rollen, versehen ist, wobei der bewegbare, die Teile tragende Gleitblock linear und kontinuierlich entlang der Laufschiene bewegbar ist. Umgekehrt sind einige lineare Führungseinheiten so gebildet, dass eine Laufschiene in Bezug auf den fixierten Gleitblock bewegt wird.

[0004] Die zweite, erwähnte Kugelspindel umfasst eine Spindelwelle, versehen mit einer spiralförmigen Kugellaufnut, gebildet unter einem vorbestimmten Führungswinkel; und ein Mutterelement, das eine Lastrollnut gegenüberliegend zu der Kugelwälznut über mehrere Kugeln besitzt und mit einem endlosen Zirkulationsdurchgangsweg für die Kugeln, die auf dieser Lastlaufnut rollen, versehen ist; wobei die Kugeln in dem endlosen Zirkulationsdurchgangsweg entsprechend der relativen Drehbewegungen dieser Spindelwelle und des Mutterelements zirkuliert werden, wobei das Mutterelement und die Spindelwelle dadurch relativ in der axialen Richtung bewegt werden.

[0005] In solchen Wälzführungseinheiten berührt ein Wälzelement, wie beispielsweise die Kugeln und Rollen, die in dem endlosen Zirkulationsdurchgangsweg zirkulieren, die Wälzelemente, positioniert an der Vorder- und Rückseite davon. Deshalb ist dort, wenn die Wälzführungseinheiten unter einer hohen Geschwindigkeit verwendet werden, die Möglichkeit vorhanden, dass sich die Wälzelemente vergleichbar früh aufgrund der gegenseitigen Abrasion von, zum Beispiel, den Wälzelementen abnutzen, und dass sich die Wälzelemente und die Lastrollfläche aufgrund von Reibungswärme festfressen. Wenn die Bewegungsrichtung umgekehrt wird, d.h. wenn die Richtung, in der die Wälzelemente zirkuliert werden, umgekehrt wird, ist die Anordnung der Wälzelemente in den endlosen Zirkulationsdurchgangswegen leicht dafür anfällig, dass sie durcheinander gelangen. In einem extremen Fall tritt ein sogenanntes Blockierphänomen auf, bei dem die Wälzelemente in dem endlosen Zirkulationsdurchgangsweg angehalten werden, so dass dort die Möglichkeit vorhanden ist, dass die Wälzführungseinheit selbst nicht mehr arbeitet. Die japanische Patentoffenlegung Nr. 315835/1999 offenbart eine Wälzführungseinheit, die so angepasst ist, um diese Nachteile einer Wälzführungseinheit zu vermeiden, in der Wälzelement-Abstandsteile zwischen Wälzelementen, benachbart zueinander in einem endlosen Zirkulationsdurchgangsweg, zwischengefügt sind.

[0006] In der Wälzführungseinheit, die in dieser Veröffentlichung offenbart ist, sind Wälzelement-Abstandsteile aus einem synthetischen Harz, bezeichnet als „Separator", alternierend mit Kugeln in dem endlosen Zirkulationsdurchgangsweg angeordnet, und der Kontakt einer Kugel mit einer anderen wird dadurch verhindert. Solche Separatoren sind in der Form einer Scheibe gebildet, wobei der äußere Durchmesser davon kleiner als der Durchmesser der Kugeln ist, und sind an sowohl der vorderen als auch der hinteren Fläche davon mit Kugelrückhaltesitzen versehen, wobei der Krümmungsradius davon größer als derjenige der sphärischen Oberfläche jeder Kugel ist. Wenn die Kugeln und Separatoren dadurch alternierend angeordnet sind, ohne dass Freiräume in dem endlosen Zirkulationsdurchgangsweg auftreten, wird jede Kugel zwischen einem Paar von Separatoren, angrenzend an die vordere und die hintere Seite davon, gehalten. Dementsprechend werden gerade dann, wenn die Richtung, in der die Kugeln zirkuliert werden, umgekehrt wird, die Kugeln mit den Separatoren in dem endlosen Zirkulationsdurchgangsweg zirkuliert, ohne zu bewirken, dass die Reihe der Kugeln und der Separatoren durcheinandergebracht wird.

[0007] Allerdings treten, wenn die Kugelrückhaltesitze, die gleitend die Kugeln berühren, konkav mit einem Krümmungsradius größer als derjenige der sphärischen Oberfläche jeder Kugel gebildet sind, gerade wie solche der Rollelement-Abstandsteile, offenbart in der japanischen Patentoffenlegung Nr. 315835/1999, Freiräume zwischen einem Umfangsbereich des Kugelrückhaltesitzes und den Kugeln auf, und die Kugeln wackeln in Bezug auf die Rollelement-Abstandsteile. Deshalb kann die mäanderförmige Bewegung der Kugeln in dem endlosen Zirkulationsdurchgangsweg nicht vollständig beseitigt werden.

[0008] Von dem Gesichtspunkt der Verhinderung einer solchen mäanderförmigen Bewegung der Kugeln in dem endlosen Zirkulationsdurchgangsweg ist es notwendig, dass sich die Kugeln setzen, ohne dass sie sich an den Kugelrückhaltesitzen der Wälzelement-Abstandsteile schütteln. Um das Erfordernis zu erfüllen, ist es notwendig, dass die Kugelrückhaltesitze so gebildet sind, dass sie konkave Oberflächen haben, die im Wesentlichen mit den sphärischen Oberflächen der Kugeln übereinstimmen. Allerdings wird, wenn die Kugelrückhaltesitze so gebildet sind, dass sie solche konkaven Oberflächen haben, der Kontaktoberflächenbereich jeder Kugel und ein relativer Kugelrückhaltesitz groß. Dies bringt eine Gefahr dahingehend mit sich, dass eine Vergrößerung in dem Gleitkontaktwiderstand der Wälzelement-Abstandsteile in Bezug auf die Kugeln, eine frühe Abnutzung an den Wälzelement-Abstandsteilen, usw., auftreten.

[0009] Die DE-A-19925040 offenbart Wälzelement-Abstandsteile, die die Wälzelemente nur an zwei äußeren Bereichen jedes Rückhaltesitzes auf einer Ebene senkrecht zu der Drehachse jedes Wälzelements berühren. Allerdings sind dabei bestimmte Nachteile vorhanden.

[0010] Die vorliegende Erfindung ist im Hinblick auf die vorstehend angegebenen Umstände gemacht worden und schafft Wälzelement-Abstandsteile, die dazu geeignet sind, die Stabilität von Wälzelementen in Bezug auf Rückhaltesitze mit einem hohen Niveau zu verbessern, die Ausrichtung der Wälzelemente und der Wälzelement-Abstandsteile in den endlosen Zirkulationsdurchgangswegen zu stabilisieren und den Gleitkontaktwiderstand, ausgeübt auf die Wälzelemente, zu verringern.

[0011] Gemäß einem Aspekt der vorliegenden Erfindung werden Wälzelement-Abstandsteile geschaffen, die in einer Wälzführungseinheit verwendet werden, in der ein Paar von Elementen eine kontinuierliche, relative Bewegung über eine Reihe von endlos zirkulierten Wälzelementen, zwischengefügt zwischen benachbarten Wälzelementen in einem endlosen Zirkulationskanal, und zirkuliert mit den Wälzelementen, vornimmt, wobei jedes der Wälzelement-Abstandsteile mit einem Paar von Rückhaltesitzen versehen ist, mit denen die Wälzelemente in Kontakt stehen, wobei die Wälzelemente nur die zwei Bereiche jedes Rückhaltesitzes berühren, die sich in der Nähe der beiden Enden davon befinden, und zwar auf einer Wälzelement-Schnittebene senkrecht zu der Drehachse jedes Wälzelements, dadurch gekennzeichnet, dass jeder Rückhaltesitz in einer konvexen Form gebildet ist.

[0012] Demzufolge besitzen die Wälzelement-Abstandsteile ein Paar von Rückhaltesitzen, mit denen die Wälzelemente gleitend in Kontakt stehen, wobei jeder Rückhaltesitz und ein relatives Wälzelement miteinander an Wälzelement-Schnittebenen senkrecht zu der Drehachse davon, an nur zwei Bereichen des Rückhaltesitzes, die sich in der Nähe beider Enden davon befinden, in Kontakt treten, und wobei jeder Rückhaltesitz eine konvexe Form besitzt.

[0013] Entsprechend solchen technischen Vorrichtungen berühren jeder Rückhaltesitz und jedes relative Wälzelement einander an Wälzelement-Schnittebenen senkrecht zu der Drehachse davon, und zwar nur an den zwei Bereichen des Rückhaltesitzes, die sich in der Nähe der beiden Enden davon befinden. Deshalb passen die spiralförmige Oberfläche einer Kugel oder die äußere Umfangsfläche einer Rolle in einem stabilen Zustand in einem relativen Rückhaltesitz zueinander und der einsitzende Zustand des Wälzelements in Bezug auf den Rückhaltesitz wird stabil. Demzufolge werden, wenn solche Wälzelement-Abstandsteile und Wälzelemente alternierend in den endlosen Zirkulationsdurchgangswegen in einer Wälzführungseinheit angeordnet sind, die Ausrichtung dieser Wälzelemente und der Wälzelement-Abstandsteile stabilisiert, und die mäanderförmige Bewegung der Wälzelemente in den endlosen Zirkulationsdurchgangswegen kann verhindert werden.

[0014] An den Wälzelement-Schnittebenen, senkrecht zu der Drehachse davon, berühren sich jeder Rückhaltesitz und jedes relative Wälzelement miteinander an nur zwei Bereichen in der Nähe der beiden Enden des Rückhaltesitzes. Zum Beispiel berühren sich, wenn das Wälzelement eine Kugel ist, die Kugel und ein relativer Rückhaltesitz miteinander ringförmig. Da nämlich die Mitte jedes Rückhaltesitzes und des relativen Wälzelements nicht in einem sich berührenden Zustand vorliegen, wird es möglich, den Kontaktbereich des Rückhaltesitzes und des Wälzelementes zu minimieren, und dadurch den Gleitkontaktwiderstand, ausgeübt auf das Wälzelement, zu verringern.

[0015] Weiterhin befinden sich, gemäß der vorliegenden Erfindung, die Mitte jedes Rückhaltesitzes und eines relativen Wälzelements in einem nicht berührenden Zustand, und die Mitte jedes Rückhaltesitzes trägt insgesamt nicht zu der Ausrichtung der Wälzelemente bei. Deshalb kann ein Verbindungsdurchgangsloch, das sich zwischen den Rückhaltesitzen erstreckt, vorgesehen werden, und dieses Verbindungsloch kann als ein Schmierölreservoir verwendet werden.

[0016] In der Kugelspindeleinheit variiert die Rollgeschwindigkeit der Kugeln, gehalten in einer spiralförmig geformten Lastwälznut einer Mutter und Kugelwälznut einer Spindelwelle, fein aufgrund von Fehlern einer Bildung dieser Nuten, so dass ein Abstand zwischen den Kugeln, die rollen, wenn sie eine Last auf die Nut der Mutter aufbringen, auch variiert. Deshalb werden, wenn die Wälzelement-Abstandsteile eine hohe Steifigkeit in der Wälzelement-Anordnungsrichtung haben, die Kugeln und die Wälzelement-Abstandsteile in einen erzwungen, drückenden Zustand in Bezug zueinander in dem endlosen Zirkulationsdurchgangsweg zu dem Zeitpunkt des Auftretens einer Verringerung in dem Abstand zwischen den Kugeln aufgrund der vorstehend angegebenen Gründe versetzt, und die Kugeln werden in dem endlosen Zirkulationsdurchgangsweg angehalten. Demzufolge ist es, im Hinblick auf die Notwendigkeit, eine feine Variation des Abstands zwischen den benachbarten Kugeln zu absorbieren, bevorzugt, den Wälzelement-Abstandsteilen in der Wälzelement-Anordnungsrichtung eine Elastizität zu geben, indem Nuten in den äußeren Umfangsoberflächen, die die Umfänge der Rückhaltesitze umgeben, angeordnet werden.

[0017] Wie vorstehend beschrieben ist, passen, gemäß den Wälzelement-Abstandsteilen der vorliegenden Erfindung, die sphärischen Oberflächen der Kugeln oder die äußeren Umfangsflächen der Rollen stabil in die Rückhaltesitze, und der Sitzzustand der Wälzelemente in Bezug auf die Rückhaltesitze wird stabil. Da sich die Mitte jedes Rückhaltesitzes und eines relativen Wälzelements in einem nicht berührenden Zustand befindet, wird es möglich, den Kontaktbereich jedes Rückhaltesitzes und eines relativen Wälzelements zu verringern, den einsitzenden Zustand der Wälzelemente in Bezug auf die Rückhaltesitze zu verbessern, die Ausrichtung der Wälzelemente und der Wälzelement-Abstandsteile in einem endlosen Zirkulationsdurchgangsweg zu stabilisieren und einen Gleitwiderstand, ausgeübt auf die Wälzelemente, zu verringern.

[0018] Eine Ausführungsform der Erfindung wird nun, anhand nur eines Beispiels, unter Bezugnahme auf die beigefügten Zeichnungen beschrieben, wobei:

[0019] Fig. 1 zeigt eine geschnittene Seitenansicht, die ein Beispiel einer Kugelspindeleinheit darstellt, in der Wälzelement-Abstandsteile gemäß der vorliegenden Erfindung mit Kugeln in einem endlosen Zirkulationsdurchgangsweg angeordnet sind;

[0020] Fig. 2 zeigt eine vordere Schnittansicht der Kugelspindeleinheit, dargestellt in Fig. 1;

[0021] Fig. 3 zeigt eine perspektivische Ansicht, die ein Wälzelement-Abstandsteil darstellt, das durch den Anmelder vorgesehen ist und zu dem Zweck einer Erläuterung beschrieben ist;

[0022] Fig. 4 zeigt eine Schnittansicht, die das Wälzelement-Abstandsteil der Fig. 3, zwischengefügt zwischen Kugeln, darstellt;

[0023] Fig. 5 zeigt eine perspektivische Ansicht, die eine andere Anordnung eines Wälzelement-Abstandsteils für den Zweck einer Erläuterung darstellt;

[0024] Fig. 6 zeigt eine perspektivische Ansicht, die eine Ausführungsform eines Wälzelement-Abstandsteils gemäß der vorliegenden Erfindung darstellt; und

[0025] Fig. 7 zeigt eine Schnittansicht, die das Wälzelement-Abstandsteil der dargestellten Ausführungsform, zwischengefügt zwischen Kugeln, darstellt.

[0026] Eine Ausführungsform eines Wälzelement-Abstandsteils gemäß der vorliegenden Erfindung wird nun im Detail auf der Grundlage der beigefügten Zeichnungen beschrieben. Zuvor werden allerdings zwei Anordnungen eines Wälzelement-Abstandsteils, vorgesehen durch den Anmelder, zu dem Zweck einer Erläuterung beschrieben.

[0027] Die Fig. 1 und Fig. 2 stellen ein Beispiel einer Kugelspindeleinheit dar, in der Wälzelement-Abstandsteile gemäß der vorliegenden Erfindung mit Kugeln in einem endlosen Zirkulationsdurchgangsweg angeordnet werden können. In denselben Zeichnungen bezeichnet ein Bezugszeichen **1** eine Spindelwelle, **2** bezeichnet Kugeln und **3** ein Mutterelement, das auf die Spindelwelle **1** über die Mehrzahl von Kugeln **2** geschraubt ist.

[0028] Die Spindelwelle **1** ist in einer äußeren Umfangsfläche davon mit einer spiralförmigen Kugelwälznut **10** versehen, während das Mutterelement **3** in einer inneren Umfangsfläche davon mit einer spiralförmigen Lastwälznut **30**, gegenüberliegend zu der Kugelwälznut **10** der Spindelwelle **1**, versehen ist. Diese Kugelwälznut **10** und die Lastwälznut **30** bilden einen spiralförmigen Lastkugeldurchgangsweg zwischen der Spindelwelle **1** und dem Mutterelement **3**. Wenn nämlich eine relative Drehbewegung an der Spindelwelle **1** und dem Mutterelement **3** auftritt, rollen die Kugeln **2** spiralförmig in dem Lastkugeldurchgangsweg, da die Kugeln **2** eine Last auf demselben Durchgangsweg aufbringen. Das Mutterelement **3** ist mit einem Rückführrohr **4** versehen, das beide Enden des Lastkugeldurchgangswegs miteinander in Verbindung setzt und miteinander verbindet, und dadurch einen endlosen Zirkulationsdurchgangsweg für die Kugeln **2** bildet. Die Kugeln **2**, die ein Rollen bzw. Wälzen in dem Lastkugeldurchgangsweg beendet haben, und die in Bezug auf eine Belastung freigegeben worden sind, werden in einen Nicht-Last-Zustand versetzt und rollen in das Rückführrohr **4**. Die Kugeln **2** springen dann über eine Distanz entsprechend zu mehreren Windungen der Kugelwälznut **10** und werden zu einem Einlass des Lastkugeldurchgangswegs zurückgeführt. Deshalb rollen, wenn die Spindelwelle **1** und das Mutterelement **3** eine relative Drehbewegung vornehmen, die Kugeln **2** von dem Lastkugelkanal zu dem Rückführrohr **4** und von dem Rückführrohr **4** zu dem Lastkugelkanal, d.h. die Kugeln werden in dem Inneren des Endlos-Zirkulationskanals, gebildet aus diesem Lastkugelkanal und dem Rückführrohr **4**, zirkuliert.

[0029] In dieser Kugelspindeleinheit sind Wälzelement-Abstandsteile **5** zwischen benachbarten Kugeln **2**, **2** so zwischengefügt, um zu verhindern, dass die Kugeln **2**, eingesetzt in dem endlosen Zirkulationsdurchgangsweg, miteinander in Kontakt treten. Obwohl es nicht entsprechend der vorliegenden Erfindung ist, stellen, zum Zwecke einer Erläuterung, die Fig. 3 und Fig. 4 Wälzelement-Abstandsteile **5** dar, die durch Bilden eines synthetischen Harzes im Wesentlichen in der Form einer Scheibe erhalten sind, und die an sowohl der vorderen als auch der Rückseite davon Rückhaltesitze **50** besitzen, mit denen die Kugeln **2** gleitend in Kontakt stehen. Die Kugeln **2** und die Wälzelement-Abstandsteile **5** sind alternierend in dem endlosen Zirkulationskanal angeordnet. Dies verhindert, dass die Kugeln **2**, die in dem endlosen Zirkulationskanal rollen, miteinander in Kontakt treten, und ermöglicht, dass die Kugeln **2** sanft zirkuliert werden, eine Drehbewegung des Mutterelements **3** in Bezug auf die Spindelwelle **1** glatt auftritt und das Auftreten von Geräuschen einer Kollision der Kugeln während eines Betriebs der Kugelspindeleinheit verringert wird.

[0030] Der Rückhaltesitz **50** ist im Wesentlichen konisch gebildet und durch Drehen einer Kurve, wobei der Krümmungsradius davon größer als derjenige der Oberfläche der Kugel **2** ist, um eine Mittenachse **0** eines Wälzelement-Abstandsteils **5** erhalten. Der Rückhaltesitz **50** ist nämlich an einer Kugelschnittebene senkrecht zu der Mitte C einer Drehung der Kugel **2** aus einer Kombination von zwei Bögen gebildet. Die Kugel **2** berührt ringmäßig und linear den Rückhaltesitz **50**. Wie in Fig. 4 dargestellt ist, berührt, auf einer Kugelschnittebene senkrecht zu der Mitte C einer Drehung der Kugel **2**, jeder Rückhaltesitz **50** die Kugel **2** an nur den zwei Bereichen des ersteren, die sich in der Nähe der beiden Enden davon befinden. Es ist nämlich ein Freiraum notwendigerweise zwischen der Kugel **2** und dem Kugelrückhaltesitz **50** so gebildet, dass sich die Breite des Freiraums stufenweise zu der Mitte des Kugelrückhaltesitzes **50** erhöht. Der Rückhaltesitz **50** und die Kugel **2** sind so angeordnet, dass sich ein Kontaktbereich des Rückhaltesitzes **50** und der Kugel **2** in der Richtung erweitert, in der die Kugel **2** rollt, d.h. unter einem Winkel von 45° in Bezug auf die Mittenachse **0** des Wälzelement-Abstandsteils **5**. Aufgrund dieser Anordnung passt, wenn die Kugeln **2** und die Wälzelement-Abstandsteile **5** so angeordnet sind, ohne dass bewirkt wird, dass Freiräume unter diesen Teilen in dem endlosen Zirkulationskanal der Kugelspindeleinheit auftreten, die sphärische Oberfläche jeder Kugel **2** in den relativen, im Wesentlichen konisch geformten Rückhaltesitz **50** hinein, und jede Kugel **2** sitzt stabil in dem relativen Rückhaltesitz **50** ein. Deshalb wackeln die Kugeln **2** nicht instabil auf den Kugelrückhaltesitzen **50** des Wälzelement-Abstandsteils **5**, so dass die Kugeln **2** und die Wälzelement-Abstandsteile **5** zirkuliert werden können, ohne dass bewirkt wird, dass sich diese Teile in einem solchen endlosen Zirkulationskanal mäanderförmig bewegen.

[0031] Jedes Wälzelement-Abstandsteil **5** ist in der Mitte davon mit einem Verbindungsloch **51** so versehen, dass sich das Verbindungsloch durch ein Paar von Rückhaltesitzen **50** davon erstreckt, die in entgegengesetzten Richtungen weisen, wobei ein Schmiermittel, das auf den relativen Kugeln **2** niedergeschlagen ist, in diesem Verbindungsloch **51** gesammelt wird. Wie vorstehend erwähnt ist, sind, in der Nähe der Mitten der Rückhaltesitze **50**, Freiräume zwischen den Kugeln **2** und den Rückhaltesitzen **50** so vorhanden, dass die Freiräume, wobei die Breite davon sehr klein ist, zwischen den Kugeln **2** und den Rückhaltesitzen **50** gerade in Bereichen um das Verbindungsloch **51** herum existieren. Deshalb wird, wenn sich die Kugeln **2** drehen, das Schmiermittel in den Verbindungslöchern **51** zwischen die Kugeln **2** und die Rückhaltesitze **50** gebracht und die Oberflächen der Wälzelement-Abstandsteile **5** und solcher der Kugeln **2** werden geschmiert.

[0032] Weiterhin ist eine ringförmige Nut **52** in der äußeren Umfangsfläche jedes Wälzelement-Abstandsteils **5**, das die Rückhaltesitze **50** davon umgibt, gebildet, und ein äußerer Umfangskantenbereich eines solchen Wälzelement-Abstandsteils **5** ist in zwei, d.h. ein Paar von ringförmigen Vorsprüngen **53**, **53**, unterteilt. Die Kugel **2** berührt nur den Bereich eines relativen, ringförmigen Vorsprungs **53** eines relativen Kugelrückhaltesitzes **50**, der sich in der Nähe eines freien Endes davon befindet, und berührt nicht den Rückhaltesitz **50** des Wälzelement-Abstandsteils **5** an dem Bereich, der sich in der Nähe der Mitte davon befindet. Deshalb werden, wenn sich ein Abstand zwischen angrenzenden Kugeln **2**, **2** während der Zirkulation davon in dem endlosen Zirkulationskanal verringert, die ringförmigen Vorsprünge **53** elastisch einfach deformiert, um die Variation des Abstands zwischen den Kugeln **2** zu absorbieren. Die Wälzelement-Abstandsteile **5**, die so gebildet sind, übernehmen nämlich die Rollen von Kissen, die die Variation des Abstands zwischen den Kugeln **2** absorbieren, und beseitigen das Problem von sich gegenseitig behindernden Bewegungen der Kugeln **2** in dem endlosen Zirkulationskanal. Diese Wälzelement-Abstandsteile tragen zu einer Vergleichmäßigung der Zirkulation solcher Kugeln **2** bei.

[0033] Fig. 5 stellt einen zweiten Typ eines Wälzelement-Abstandsteils, der durch den Anmelder vorgesehen ist, dar. Ein Wälzelement-Abstandsteil **5a** besitzt eine Struktur im Wesentlichen identisch zu derjenigen des Wälzelement-Abstandsteils **5**, das in Fig. 3 und Fig. 4 dargestellt ist. In dem Wälzelement-Abstandsteil der Fig. 5 ist der Durchmesser eines Verbindungslochs **51**, gebildet in der Mitte davon, größer als derjenige des Wälzelement-Abstandsteils **5** des ersten Abstandsteils, so dass eine solche Menge eines Schmiermittels, die dem im Durchmesser vergrößerten Bereich des Verbindungslochs **51** entspricht, zusätzlich darin bevorratet werden kann. Genauer gesagt beträgt der Durchmesser des Verbindungslochs **51** ungefähr 2/3 desjenigen, mit dem das Wälzelement-Abstandsteil **5a** gebildet wurde. Ein Rückhaltesitz **54**, den die Kugel **2** berührt, ist in eine konkave Form im Wesentlichen in Übereinstimmung mit der Form der sphärischen Oberfläche der Kugel **2** so gebildet, dass die gesamte Oberfläche des Rückhaltesitzes **54** die sphärische Oberfläche der Kugel **2** berührt. Sogar dann, wenn die Kugel **2** demzufolge die gesamte Oberfläche des Rückhaltesitzes **54** berührt, erhöht sich der Kontaktbereich der Kugel **2** und des Rückhaltesitzes **54** nicht extrem, da das Verbindungsloch **51** ausreichend groß gebildet ist, und da das Wälzelement-Abstandsteil **5a** nicht im Wesentlichen einen Gleitkontaktwiderstand der Kugel **2** verursacht, um sich so im Vergleich zu dem Wälzelement-Abstandsteil **5** der ersten Ausführungsform zu erhöhen. Die Strukturen in dieser Anordnung, die identisch zu den entsprechenden Strukturen in der ersten Anordnung sind, sind mit Bezugszeichen, identisch zu solchen in der ersten Anordnung, bezeichnet, und eine detaillierte Beschreibung davon wird weggelassen.

[0034] In dem Wälzelement-Abstandsteil **5a**, das so gebildet ist, passt auch die sphärische Oberfläche der Kugel **2** in den Rückhaltesitz **54** hinein und die Kugel **2** sitzt in einem stabilen Zustand in dem Rückhaltesitz **54** ein. Dementsprechend können die Kugeln **2** in dem endlosen Zirkulationskanal zirkuliert werden, ohne zu verursachen, dass die Kugeln **2** instabil auf den Kugelrückhaltesitzen **54** der Wälzelement-Abstandsteile **5a** wackeln, und ohne zu bewirken, dass sich die Kugeln **2** und die Wälzelement-Abstandsteile **5a** in demselben Zirkulationskanal mäanderförmig bewegen.

[0035] Als nächstes stellen die Fig. 6 und die Fig. 7 eine Ausführungsform des Wälzelement-Abstandsteils gemäß der vorliegenden Erfindung dar. Ein Wälzelement-Abstandsteil **5b** dieser Ausführungsform besitzt eine Struktur im Wesentlichen identisch zu derjenigen des Wälzelement-Abstandsteils **5a**, dargestellt in Fig. 5, allerdings ist die Form des Rückhaltesitzes **55**, mit dem die Kugel **2** in Kontakt tritt, unterschiedlich gegenüber derjenigen des Rückhaltesitzes **50** in Fig. 3 und Fig. 4 oder des Rückhaltesitzes **54** in Fig. 5. Wie in einer Schnittansicht der Fig. 7 dargestellt ist, ist ein solcher Rückhaltesitz **55** nicht in einer konkaven Form, sondern in einer konvexen Form, gebildet, so dass die sphärische Oberfläche der Kugel **2** in Form einer Linie den Rückhaltesitz ringförmig berührt. Ein Kontaktbereich des Rückhaltesitzes **55** und der Kugel **2** ist so vorgesehen, um sich in der Wälzrichtung der Kugel **2** zu erweitern, d.h. unter einem Winkel von 45° in Bezug auf die Mitte **0** des Wälzelement-Abstandsteils **5b**. Das Wälzelement-Abstandsteil dieser Ausführungsform ist identisch in Bezug auf solche mit den Bezugszeichen **5**, **5a** der ersten und der zweiten Anordnung, die zur Erläuterung beschrieben sind.

[0036] Aufgrund dieser Anordnung wackeln, wenn die Kugeln **2** und die Wälzelement-Abstandsteile **5b** der dargestellten Ausführungsform so angeordnet sind, ohne dass ein Freiraum dazwischen in dem endlosen Zirkulationskanal in der Kugelspindeleinheit hervorgerufen wird, die Kugeln **2** nicht instabil auf irgendeinen der Kugelrückhaltesitze **50** des Wälzelement-Abstandsteils **5b**, und die Kugeln **2** und die Wälzelement-Abstandsteile **5b** können zirkuliert werden, ohne zu bewirken, dass sich dieselben Teile mäanderförmig in dem endlosen Zirkulationskanal bewegen.

[0037] In dieser Ausführungsform ist die Beschreibung anhand der Wälzelement-Abstandsteile vorgenommen worden, die unter den Kugeln **2** zwischengefügt sind, die als Beispiel herangezogen sind, allerdings kann die Ausführungsform in derselben Art und Weise auch dann gebildet werden, wenn die Wälzelemente Rollen sind.

Patentansprüche

1. Wälzelement-Abstandsteile, verwendet in einer Wälzführungseinheit, in der ein Paar von Elementen (**1**, **3**) eine kontinuierliche, relative Bewegung über eine Reihe von endlos zirkulierten Wälzelementen (**2**), zwischengefügt zwischen benachbarten Wälzelementen (**2**) in einem endlosen Zirkulationskanal, und zirkuliert mit den Wälzelementen (**2**) vornimmt, wobei jedes der Wälzelement-Abstandsteile (**5b**) mit einem Paar von Rückhaltesitzen (**55**) versehen ist, mit denen die Wälzelemente (**2**) in Kontakt stehen, wobei die Wälzelemente (**2**) nur die zwei Bereiche jedes Rückhaltesitzes (**55**) berühren, die sich in der

Nähe der beiden Enden davon befinden, und zwar auf einer Wälzelement-Schnittebene senkrecht zu der Drehachse jedes Wälzelements (**2**), **dadurch gekennzeichnet**, dass jeder Rückhaltesitz (**55**) in einer konvexen Form gebildet ist.

2. Wälzelement-Abstandsteile nach Anspruch 1, wobei die Wälzelemente (**2**) Kugeln sind und wobei die sphärische Oberfläche der Kugeln jeden Rückhaltesitz (**55**) entlang einer ringförmigen Linie berührt.

3. Wälzelement-Abstandsteile nach Anspruch 1 oder 2, wobei die zwei Kontaktbereiche, gebildet durch den Rückhaltesitz (**55**) und das Wälzelement (**2**), so vorgesehen sind, um sich unter einem Winkel von 45° in der Wälzrichtung des Wälzelements zu erweitern.

4. Wälzelement-Abstandsteile nach Anspruch 1, 2 oder 3, wobei zentrale Bereiche des Paars der Rückhaltesitze (**55**) mit einem Durchgangsverbindungsloch (**51**) versehen sind, das sich zwischen diesen Rückhaltesitzen (**55**) erstreckt, wobei der Durchmesser des Durchgangsverbindungslochs ungefähr 2/3 des Durchmessers des Wälzelement-Abstandsteils beträgt.

5. Wälzelement-Abstandsteile nach einem vorhergehenden Anspruch, wobei eine Nut (**52**) in einer äußeren Umfangsfläche, die einen Umfang der Rückhaltesitze (**55**) umgibt, gebildet ist, wodurch jedem Wälzelement-Abstandsteil (**5b**) eine Elastizität in der Richtung der Anordnung der Wälzelemente (**2**) gegeben wird.

6. System aus Wälzelementen und Wälzelement-Abstandsteilen zur Verwendung in einer Wälzführungseinheit, in der ein Paar von Elementen (**1**, **3**) so angepasst ist, um eine kontinuierliche, relative Bewegung über eine Reihe von endlos zirkulierten Wälzelementen (**2**) vorzunehmen, wobei das System eine Mehrzahl von Wälzelementen (**2**) und eine Mehrzahl von Wälzelement-Abstandsteilen (**5b**), angepasst so, um zwischen benachbarten solchen der Wälzelemente (**2**) in einem endlosen Zirkulationskanal einer Wälzführungseinheit zwischengefügt zu sein, um mit den Wälzelementen (**2**) zu zirkulieren, aufweist, wobei jedes der Wälzelement-Abstandsteile (**5b**) mit einem Paar von Rückhaltesitzen (**55**) versehen ist, die die Wälzelemente (**2**) berühren, wobei die Wälzelemente (**2**) nur die zwei Bereiche jedes Rückhaltesitzes (**55**) berühren, die sich in der Nähe von beiden Enden davon, an einer Wälzelement-Schnittebene, senkrecht zu der Drehachse jedes Wälzelements (**2**), befinden, dadurch gekennzeichnet, dass jeder Rückhaltesitz (**55**) in einer konvexen Form gebildet ist.

(54) Bezeichnung: **Distanzstück für Linearführungen und mit einem solchen ausgerüstete Linearführung**

Beschreibung

[0001] Die vorliegende Erfindung bezieht sich auf ein Distanzstück, das zwischen Rollen, angeordnet in einem endlosen Zirkulationsdurchgangsweg einer Linearbewegungsvorrichtung, zwischengefügt ist, und bezieht sich auch auf eine Linearbewegungsvorrichtung, die mit einem solchen Distanzstück versehen ist.

[0002] Es ist herkömmlich bekannt, Distanzstücke zwischen Rollelementen, wie beispielsweise Kugeln oder Rollen, aufgenommen und angeordnet in dem Endlosroll-Element-Zirkulationsdurchgangsweg einer Linearrollbewegungsführungsvorrichtung, einer Kugel-Spindel, Kugel-Keilwellen, oder dergleichen, zwischenzufügen, die hier allgemein als „Linearbewegungsvorrichtung" bezeichnet werden. Die Anordnung solcher Distanzstücke verhindert, dass die Rollelemente direkt miteinander in Kontakt treten, wobei ein geeignetes Distanzstück beibehalten wird, um den Betrieb der Linearbewegungsvorrichtung störungsfrei zu gestalten und effektiv die Entwicklung von Geräusch, verursacht durch das Aufeinandertreffen der jeweiligen Rollelement, zu verhindern.

[0003] Allerdings ist es in der Anordnung, in der die Distanzstücke jeweils zwischen den Rollelementen zwischengefügt sind, unvermeidbar, einen dimensionsmäßigen Fehler zwischen einer gesamten Länge einer Endlosreihe der Rollelemente und den Distanzstücken, angeordnet alternierend in dem Zustand, dass sie miteinander in Berührung stehen, und einer Gesamtlänge des Endlos-Zirkulationsdurchgangswegs, in dem diese Rollelemente und die Distanzstücke aufgenommen sind, zu verursachen. Um einen solchen Defekt zu vermeiden, ist mindestens ein Distanzstück, das eine Länge unterschiedlich zu derjenigen eines anderen Distanzstücks besitzt, als ein einen Fehler absorbierendes Distanzstück eingesetzt.

[0004] In einem Fall eines Anpassens der Struktur, in der ein einen solchen Fehler absorbierendes Distanzstück eingesetzt ist, ist es, um die geeignetesten Anordnungs-Zustände der Rollelemente für eine Vielzahl von Vorrichtungen oder unterschiedlichen Arten von Vorrichtungen zu erhalten oder zu realisieren, notwendig, eine Vielzahl von Fehler absorbierenden Distanzstücken zu präparieren, die unterschiedliche Längen haben, und sie durch geeignetes Auswählen für jede der Linearbewegungsanordnungen oder -vorrichtungen einzusetzen. Allerdings ist es mühsam und unbequem für die Wartung der Teile oder dergleichen, immer eine Vielzahl von Fehler absorbierenden Distanzstücken für diese unterschiedlichen Arten von Anordnungen oder Vorrichtungen zu präparieren oder zu reservieren. Weiterhin ist es, da die Distanzstücke gewöhnlich aus Harzmaterialen gebildet sind, auch notwendig, eine Vielzahl von Arten von Formen zu präparieren oder herzustellen, um die Distanzstücke herzustellen, was Kosten mit sich bringt, was demzufolge nicht passend ist.

[0005] Noch weiter ist dabei eine Möglichkeit vorhanden, dass ein leichter Zwischenraum zwischen den Rollelementen und den festen Distanzstücken sogar dann vorhanden ist, wenn das Fehler absorbierende Distanzstück eingesetzt wird, und ein solcher Zwischenraum kann aufgrund einer Abnutzung der Distanzstücke über eine langzeitige Benutzung auch dann erhöht werden, wenn die Anordnung oder Vorrichtung mit im Wesentlichen keinem dimensionsmäßigen Fehler zum Zeitpunkt der Montage zusammengebaut wird.

[0006] Um einen solchen Defekt zu beseitigen, wird eine Gegenmaßnahme einer Verwendung eines elastischen Distanzstücks, das eine Elastizität besitzt, vorgenommen. Wenn solche elastischen Distanzstücke verwendet werden, werden die elastischen Distanzstücke in der endlosen Reihe geschrumpft, um dadurch einen im Wesentlichen vollständigen (dichten) Kontakt-Zustand zwischen den Rollelementen und den Distanzstücken zu erhalten, und sogar dann, wenn die Rollelement und die Distanzstücke abgenutzt sind, werden die Distanzstücke durch deren Elastizität expandiert, so dass die dichten Kontakt-Zustände beibehalten werden können.

[0007] Es existieren bekannte Beispiele, die solche elastischen Distanzstücke, wie sie in der Japanischen Gebrauchsmuster-Offenlegung No. SHO 53-90158 offenbart sind, die eine Struktur darstellt, bei der eine Feder zwischen einem Paar von scheibenähnlichen Kugel-Rückhalteteüen zwischengefügt ist, und auch wie sie in dem US-Patent Nr. 2,827,345 offenbart sind, das eine Struktur mit zwei scheibenförmigen, elastischen Elementen darstellt, die vertiefte Bereiche angrenzend aneinander haben, verwenden. Allerdings ist in solchen Strukturen, bei denen das elastische Distanzstück aus einer Vielzahl von Bereichen oder Elementen zusammengesetzt ist, eine Gefahr vorhanden, dass sich das Distanzstück während der Benutzung davon zerlegen kann, was demzufolge die Wartung davon schwierig und mühsam gestalten wird, und die Kosten unvermeidbar erhöhen wird, was demzufolge nicht praktikabel ist.

[0008] Weiterhin schafft, um das vorstehende Problem zu lösen, der Stand der Technik weiterhin ein elastisches Distanzstück, das aus einem Einzelelement aufgebaut ist, wie es in der Japanischen Gebrauchsmuster-Veröffentlichung No. SHO 51-10285 offenbart ist, mit einem rohrförmigen Distanzstück-Körper, gebildet mit sphärischen Rückhalteflächen an beiden Endflächen in der Vorschubrichtung davon, um die Kugel zu halten, und ausgebildet mit einem Schlitz, der einen inneren Umfang und einen äußeren Umfang des rohrförmigen Distanzstück-Körpers verbindet. Allerdings ist es, da dieses elastische

Distanzstück elastisch so deformiert wird, dass der Ring an beiden Seiten des Schlitzes geöffnet ist, unmöglich, einen deformierbaren (verschiebbaren) Betrag in der Vorschubrichtung des elastischen Distanzstücks groß zu machen. Hierdurch ist es nicht sicher, dass ein solches elastisches Distanzstück geeignet für verschiedene Arten von Linearbewegungsanordnungen oder -vorrichtungen, um sie herzustellen, verwendbar ist, und dabei kann ein Fall hervorgerufen werden, bei dem eine relative Bewegung der Kugeln, die in den belasteten Bereich und den nicht belasteten Bereich hinein und heraus gehen, auftritt. Demzufolge kann eine störungsfreie Zirkulation der Rollelemente nicht erwartet werden.

[0009] Darüber hinaus schafft ein Stand der Technik ein elastisches Distanzstück, das aus einem einzelnen Element aufgebaut ist, wie dies in der Japanischen Patenveröffentlichung No. Hei 4-27405 offenbart ist, mit einer Struktur, in der das Distanzstück, an seinen beiden Enden in der Vorschubrichtung, mit gekrümmten Rückhalteflächen zum Halten der Rolle versehen ist, und wobei Ausschnitte an den gekrümmten Rückhalteflächen so gebildet sind, um sich in einer axialen Richtung davon zu erstrecken. Allerdings wird ein solches elastisches Distanzstück elastisch so deformiert, dass beide Seiten des Ausschnitts der gekrümmten Rückhalteflächen geöffnet sind, so dass es nicht möglich ist, einen deformierbaren (verschiebbaren) Betrag in der Vorschubrichtung des elastischen Distanzstücks groß zu machen.

[0010] Das Dokument CH-A-621 608 offenbart ein Distanzstück für eine Linearbewegungsvorrichtung, die zwischen Rollen, angeordnet in einem endlosen Zirkulationsdurchgangsweg der Linearbewegungsvorrichtung, zwischengefügt werden soll, wobei das Distanzstück einen massiven Körperbereich, gebildet aus einem elastischen Material, besitzt, und U-förmige Vertiefungen, gebildet in beiden Endbereichen davon in einer Vorschubrichtung des Distanzstücks, wenn es sich in dem endlosen Zirkulationsdurchgangsweg bewegt, aufweist, wobei die U-förmigen Vertiefungen eine Form kleiner als die Umfangsform der Rolle haben, so dass obere und untere Armbereiche des Distanzstücks, die Rollen tragend, elastisch voneinander weg deformierbar sind.

[0011] Die FR-A-1 104 502 offenbart Verbesserungen, die sich auf eine Vorrichtung zum Beibehalten der Beabstandung von Rollelementen in Kugellagern, und dergleichen, beziehen.

[0012] Die LU-A-61 956 offenbart ein Kegelrollenlager und ein Verfahren zum Montieren eines solchen Lagers.

[0013] Die JP-A-06 173946 offenbart eine direkt wirkende Führungsvorrichtung.

[0014] Eine Aufgabe der vorliegenden Erfindung ist es, im Wesentlichen Defekte oder Nachteile, die im Stand der Technik vorhanden sind, der vorstehend erwähnt ist, zu beseitigen, und ein Distanzstück, aufgebaut aus einem Einzelelement, einer Linearbewegungsvorrichtung, geeignet dazu, dass sie einen relativ großen, elastisch deformierbaren Betrag in deren Vorschubrichtung besitzt, zu schaffen, und auch eine Linearbewegungsvorrichtung, versehen mit solchen Distanzstücken, zu schaffen.

[0015] Gemäß einem ersten Aspekt der Erfindung wird ein Distanzstück für eine Linearbewegungsvorrichtung geschaffen, das zwischen Rollen, angeordnet in einem endlosen Zirkulationsdurchgangsweg der Linearbewegungsvorrichtung, zwischengefügt werden soll, wobei das Distanzstück einen Körperbereich besitzt, der gekrümmte Rückhalteflächenbereiche aufweist, die eine Form entsprechend zu einer Umfangsform der Rolle aufweisen, um die Rollen an beiden Endabschnitten davon in einer Vorschubrichtung des Distanzstücks zu tragen, wenn es sich in dem endlosen Zirkulationsdurchgangsweg bewegt, dadurch gekennzeichnet, dass der Körperbereich weiterhin ein Paar eines oberen und unteren Seitenflächenbereichs, die die gekrümmten Rückhalteflächenbereiche verbinden, aufweist, und ein innerer, hohler Bereich in dem Körperbereich des Distanzstücks durch die gekrümmten Rückhalteflächenbereiche und das Paar des oberen und unteren Seitenflächenbereichs definiert ist, wobei sich der innere, hohle Bereich in einer Richtung im Wesentlichen parallel zu einer axialen Richtung der Rolle erstreckt so, dass eine der gekrümmten Rückhalteflächenbereiche elastisch zueinander hin in der Vorschubrichtung deformierbar ist.

[0016] In einer bevorzugten Ausführungsform besitzt der Körperbereich eine Länge in der axialen Richtung der Rolle, die kleiner als eine axiale Länge der Rolle ist, und besitzt eine Höhe kleiner als eine Länge der Rolle in einer Richtung normal zu der axialen Richtung davon. Der Körperbereich kann aus einem synthetischen Harzmaterial über einen Spritzgieß-Vorgang gebildet sein.

[0017] Gemäß dem Distanzstück der Erfindung ist es, da das Distanzstück als ein einzelnes Element ausgebildet ist, einfach, die Distanzstücke zu handhaben oder zu warten, was zu einer Kostenverringerung beiträgt. Weiterhin kann, da eine der Rückhalteflächen elastisch zu der anderen einen davon hin deformierbar ist, das Distanzstück ausreichend elastisch in seiner Vorschubrichtung deformiert werden. Deshalb sind solche Distanzstücke bei vielen Arten von Typen einer Linearbewegungsvorrichtung, oder dergleichen, anwendbar, was demzufolge sehr praktikabel ist.

[0018] Ein sehr elastisch deformierbarer Betrag des

Distanzstücks in der Vorschubrichtung macht es möglich, eine ausreichende, relative Bewegung der Rollen an beiden Seiten des Distanzstücks sicherzustellen, und demzufolge kann die Zirkulation zwischen dem belasteten Bereich und dem nicht belasteten Bereich in dem Rollenzirkulationsdurchgangsweg störungsfrei gestaltet werden. Weiterhin ist, in dem angeordneten Zustand der Distanzstücke in dem Zirkulationsdurchgangsweg, da die Rollen komprimiert und kontrahiert werden, der Raum zwischen der endlosen Reihe der Rollen und der Distanzstücke, alternativ angeordnet in dem Zirkulationsdurchgangsweg, kein Raum (d.h. Minus-Raum) in Bezug auf den Wandbereich davon gebildet, so dass die Distanzstücke unter den vorbestimmten, konstanten Positionen zwischen den Rollen aufgrund der Rückstellkraft positioniert werden können, was demzufolge verhindert, dass die Rollen die Distanzstücke während der Rollbewegung davon einschneiden.

[0019] Gemäß einem bevorzugten Merkmal der Erfindung weist das Distanzstück ein vorstehendes Teil auf, das an einer der oberen und unteren Seitenflächenbereiche des Körperbereichs gebildet ist, so, um sich in einer Richtung senkrecht zu einer axialen Richtung der Rolle zu erstrecken. Gemäß einem weiteren, bevorzugten Merkmal der Erfindung weist das vorspringende Teil ein vorstehendes Ende auf, das eine runde Form besitzt. Das vorspringende Teil kann ein Plattenelement, gebildet an im Wesentlichen dem zentralen Bereich eines Seitenoberflächenbereichs des Distanzstücks in der Vorschubrichtung, sein. Genauer gesagt können die Distanzstücke mit Vorsprungsplatten gebildet sein, die in eine Führungsnut, gebildet an dem Rollenzirkulationsdurchgangsweg, eingesetzt sind, so dass die Rollen störungsfrei entlang der vorbestimmten Spur in dem Zirkulationsdurchgangsweg, ohne darin mäanderförmig zu laufen, bewegt und geführt werden.

[0020] Gemäß einem bevorzugten Merkmal der Erfindung ist der Distanzstück-Körper aus einem einzelnen, elastischen Material gebildet.

[0021] Vorzugsweise besitzt der Körperbereich eine Länge in der axialen Richtung der Rolle, die kleiner als eine axiale Länge der Rolle ist, und besitzt eine Höhe kleiner als eine Länge der Rolle in einer Richtung normal zu der axialen Richtung davon.

[0022] Vorzugsweise ist das Distanzstück als ein einzelnes Element gebildet, so dass es einfach ist, die Distanzstücke zu handhaben oder zu warten, was demzufolge zu einer Kostenverringerung beiträgt. Weiterhin kann, da eine der gekrümmten Rückhalteflächen elastisch zu der anderen einen davon hin deformierbar ist, das Distanzstück ausreichend elastisch in seiner Vorschubrichtung deformiert werden. Deshalb sind die Distanzstücke bei vielen Arten von Typen einer Linearbewegungsvorrichtung, oder dergleichen, anwendbar, so dass sie umfangreich praktikabel sind.

[0023] Gemäß einem zweiten Aspekt der Erfindung wird eine Linearbewegungsvorrichtung geschaffen, die aufweist: ein Führungsschienenelement, ausgebildet mit einer Rollenfläche;
ein Gleitelement, befestigt so, um relativ zu dem Führungsschienenelement, ausgebildet mit einem Rollenzirkulationsdurchgangsweg, umfassend eine belastete Rollenrollnut, die der Rollenrollfläche des Führungsschienenelements gegenüberliegt, wenn sie montiert ist, bewegbar zu sein, wobei das Gleitelement mit einer Führungsnut, die entlang des Rollenzirkulationsdurchgangswegs gebildet ist, versehen ist;
eine Anzahl von Rollen, angeordnet in dem Rollenzirkulationsdurchgangsweg so, um darin in Übereinstimmung mit der relativen Bewegung des Gleitelements in Bezug auf das Führungsschienenelement zu zirkulieren; und eine Anzahl von Distanzstücken, angeordnet zwischen den Rollen in einer alternierenden Art und Weise, wobei jedes der Distanzstücke gemäß dem ersten Aspekt der Erfindung ausgebildet ist.

[0024] In den beigefügten Zeichnungen:

[0025] Fig. 1 zeigt eine perspektivische Ansicht, die eine Linearrollbewegungsführungsvorrichtung darstellt, die mit einem Distanzstück gemäß einer ersten Ausführunsgform der vorliegenden Erfindung versehen ist;

[0026] Fig. 2 zeigt eine Schnittansicht einer Linearrollbewegungsführungsvorrichtung, die mit einem Distanzstück gemäß der ersten Ausführungsform versehen ist;

[0027] Fig. 3 zeigt eine Schnittansicht eines Kugelzirkulations-Durchgangswegs entlang einer axialen Richtung einer Schiene der Linearrollbewegungsvorrichtung der Fig. 1;

[0028] Fig. 4 zeigt eine perspektivische Ansicht des Distanzstücks und der Rollen gemäß der ersten Ausführungsform;

[0029] Fig. 5 zeigt eine Schnittansicht, die das Distanzstück und die Rollen gemäß der ersten Ausführungsform darstellt;

[0030] Fig. 6 zeigt eine Schnittansicht einer Linearfollbewegungsführungsvorrichtung, versehen mit einem Distanzstück, gemäß einer zweiten Ausführungsform der vorliegenden Erfindung;

[0031] Fig. 7 zeigt eine Teilschnittansicht der Fig. 6 in einem vergrößerten Maßstab;

[0032] Fig. 8 zeigt eine Schnittansicht eines Rollenzirkulationsdurchgangswegs entlang einer axialen Richtung einer Schiene der Linearbewegungsvorrichtung der Fig. 6;

[0033] Fig. 9 zeigt eine perspektivische Ansicht des Distanzstücks und der Rollen gemäß der zweiten Ausführungsform; und

[0034] Fig. 10 zeigt eine Schnittansicht, die das Distanzstück und die Rollen gemäß der zweiten Ausführunsform darstellt.

[0035] Wie die Fig. 1 und Fig. 2 zeigen, ist eine Linearrollbewegungsführungsvorrichtung **21**, versehen mit Distanzstücken **20**, gemäß der ersten Ausführungsform der vorliegenden Erfindung so angepasst, um linear ein bewegbares Element, wie beispielsweise einen Tisch, oder dergleichen, an einem fixierten (fixierenden) Element, wie beispielsweise einem Bett, einem Sattel bzw. Schlitten, oder dergleichen, zu führen. Die Linearrollbewegungsführungsvorrichtung **21** weist eine Führungsschiene (Spur-Führungswelle) **22**, angeordnet an dem fixierten Element, und gebildet aus Rollen-(Rollelement)-Rollflächen **22a** und Kugelrollnuten **22b**, die sich entlang einer Längsrichtung davon erstrecken, einem Gleitelement **33**, gebildet mit einem Rollenzirkulationsdurchgangsweg, umfassend eine belastete Rollen-Rollnut **34a** entsprechend zu der Rollen-Rollfläche **22a** der Führungsschiene **22**, und montiert mit der Führungsschiene **22**, um relativ entlang der Führungsschiene **22** bewegbar zu sein, eine Anzahl von Rollen (Rollelementen) **24**, **24**, --, **24**, angeordnet in dem Rollenzirkulationsdurchgangsweg und darin in Übereinstimmung mit der relativen Bewegung des bewegbaren Blocks **33** in Bezug auf die Führungsschiene **22** zirkulierend, und eine Mehrzahl von Distanzstücken **20**, **20**, --, **20**, zwischengefügt alternierend zwischen einer Vielzahl von Rollen **24**, auf. Jede Rolle **24** besitzt eine zylindrische Form, die einen kreisförmigen Querschnitt, geschnitten entlang der Rollrichtung davon, besitzt.

[0036] Die Rollen-Rollfläche **22a** bildet eine horizontal flache Oberfläche und die Kugel-Rollnut **22b** besitzt eine kreisförmige Querschnittsform.

[0037] Die Führungsschiene **22** besitzt ein Element mit einem langen Maßstab, das einen im Wesentlichen rechtwinkligen Querschnitt besitzt. Die zwei Reihen der Rollen-Rollflächen **22a** als Spuren zum Rollen der Rollen **24** sind an Seitenendbereichen der oberen Oberfläche der Führungsschiene **22** so gebildet, um sich entlang der gesamten Längsrichtung davon zu erstrecken, und zwei Reihen der Kugel-Rollennuten **22b** als Führung zum Rollen der Kugeln **25** sind auch an einem oberen Bereich jeder der Seitenflächen der Führungsschiene **22** gebildet, um sich so entlang der gesamten Längsrichtung davon zu erstrecken. Eine Mehrzahl von Schraubenlöchern zum Befestigen der Führungsschiene **22** an dem befestigten Element ist in der Längsrichtung der Führungsschiene **22** gebildet. Weiterhin sollte angemerkt werden, dass eine gekrümmte Führungsschiene anstelle der linearen Führungsschiene, dargestellt in Fig. 1, und in dem dargestellten Beispiel, wie dies vorstehend angegeben ist, verwendet werden kann, obwohl die oberen zwei Reihen der Rollen-Rollflächen **22a** und vier Seitenreihen der Kugel-Rollnuten **22b** (sechs Reihen insgesamt) an der Führungsschiene **22** gebildet sind, wobei die Anzahl der Reihen entsprechend dem Design, der Benutzung, der Aufgaben der Linearbewegungsführungsvorrichtung **21** geändert werden kann.

[0038] Der bewegbare Block **33** weist einen Körperbereich **34** und Endabdeckungen (Platten) **35**, angeordnet an beiden Längsendseiten des Körperbereichs **34**, auf, wobei der Körperbereich **34** und die Endabdeckungen **35** zusammen mittels Schrauben verbunden sind. Wie in Fig. 2 dargestellt ist, ist der Körperbereich **34** aus einem Körperblock **36a** und Form-Produkten **36b** und **36c** aufgebaut. Der Körperblock **36a** besitzt eine feste Struktur, gebildet aus einem festen Material, wie beispielsweise aus Stahl, um so einer Last, aufgebracht auf den bewegbaren Block **33**, standzuhalten, und ist, an seiner oberen Oberfläche, wie sie zu sehen ist, mit Schraubenlöchern (siehe Fig. 1) zum Befestigen eines Objekts, das durch die Führungsvorrichtung geführt werden soll, ausgebildet. Die Form-Produkte **36b** und **36c** sind integral mit dem Körperblock **36a** durch Einspritzen eines geschmolzenen Harzes in eine Form, in der der Körperblock **36a** platziert ist, gebildet, d.h. durch ein so genanntes Einsatz-Formungsverfahren. Weiterhin kann ein Metall, wie beispielsweise Aluminium, anstelle des Harzes verwendet werden, und, in einem solchen Fall, ist der Körperbereich über ein Spritzgießverfahren gebildet. Andererseits können, anstelle des vorstehenden Verfahrens, die Form-Produkte **36b** und **36c** unabhängig von dem Körperblock **36a** hergestellt werden, die später montiert werden, oder können integral über ein MIM (Metallspritzgießform) Verfahren gebildet werden.

[0039] Der Körperbereich **34** weist, um einen umgekehrten, im Wesentlichen U-förmigen Querschnitt, wie dies in Fig. 2 zu sehen ist, zu erreichen, einen horizontalen Bereich **36**, der der oberen Fläche der Führungsschiene **22** gegenüberliegt (dazu hinweist), und bilaterale Rand-(Schenkel)-Bereiche **37**, die sich nach unten von beiden Endbereichen des horizontalen Bereichs **36** erstrecken und gegenüberliegend zu den Seitenflächen der Führungsschienen **22** liegen, wenn der bewegbare Block **33** mit der Führungsschiene **22** zusammengebaut ist, auf.

[0040] Der horizontale Bereich **36** ist mit zwei Reihen von belasteten Rollen-Rollnuten **34a**, jeweils zu den zwei Rollen-Rollflächen **22a**, gebildet an der oberen Fläche der Führungsschiene **22**, gegenüberliegend, ausgebildet, und die Randbereiche **37** sind jeweils mit zwei Reihen der belasteten Kugel-Rollnuten **34b**, die den zwei Reihen der Kugel-Rollnuten **22b**, gebildet an jedem Seitenbereich der Führungsschiene **22**, gegenüberliegen, ausgebildet. Die Rollen-Rollnut **34a** besitzt eine rechtwinklige Querschnittsform, und die Rollen **34** rollen auf oberen Bodenflächen der Rollen-Rollnuten **34a**. Die bilateralen, innenseitigen Flächen der Rollen-Rollnuten **34a** liegen parallel zueinander, und ein kleiner Zwischenraum ist zwischen Endflächen der Rollen **24** und den Innenseitenflächen der Rollen-Rollnut **34a** gebildet. Entsprechend einer solchen Struktur wird die Rolle **24** durch die bilateralen Innenseitenflächen der Rollen-Rollnut **34a** geführt. Die Tiefe der Rollen-Rollnut **34a** ist so gebildet, dass sie kleiner als die radiale Länge der Rolle **34** ist, und ist, zum Beispiel, ungefähr von der Hälfte der Länge des Radius der Rolle **34**.

[0041] Belastete Rollen-Rolldurchgangswege A und belastete Rollen-Rolldurchgangswege A' sind in Kombination mit den Rollen-Rollflächen **22a** und den belasteten Rollen-Rollnuten **34a** und den Kugel-Rollnuten **22b** und den belasteten Kugel-Rollnuten **34b** jeweils gebildet.

[0042] Der horizontale Bereich **36** ist mit zwei Durchgangslöchern ausgebildet, die sich parallel zu den belasteten Rollen-Rollnuten **34a** erstrecken, und rohrförmige Bereiche der Form-Produkte **36c** sind integral mit diesen Durchgangslöchern ausgebildet. Rückführkanäle B sind in den rohrförmigen Bereichen der Form-Produkte **36c**, ausgebildet mit den Durchgangslöchern, zum Zurückführen der Rollen **24**, **24**, --, **24** ausgebildet.

[0043] Die Randbereiche **37** sind auch mit Durchgangslöchern ausgebildet, die sich jeweils parallel zu den belasteten Kugel-Rollnuten **34b** erstrecken, und rohrförmige Bereiche der Form-Produkte **36c** sind integral mit diesen Durchgangslöchern ausgebildet. Rückführkanäle B' sind in den rohrförmigen Bereichen der geformten Produkte **36c**, ausgebildet mit den Durchgangslöchern, zum Zurückführen der Kugeln **25**, **25**, --, **25** ausgebildet.

[0044] Das Form-Produkt **36b** ist integral mit der unteren Oberfläche des horizontalen Bereichs **36** und den gesamten Innenseitenflächen der Randbereiche **37** des Körperblocks **36a** ausgebildet. Rollen-Rückhaltebereiche (Rückhalteeinrichtungen) **39** sind auf dem Form-Produkt **36b** gebildet, um zu verhindern, dass die Blockrollen **24** aus den belasteten Rollen-Rolldurchgangswegen A zu einem Zeitpunkt herauskommen, wenn deren bewegbarer Block **33** von der Führungsschiene **22** entfernt wird.

[0045] Wie Fig. 3 zeigt, ist das Form-Produkt **36c** mit bogenförmigen, inneren Umfangs-Führungsbereichen **36d** ausgebildet, die an beiden Endbereichen des Körperblocks **36a** vorstehen, um einen Rollelement-(Rollen)-Rollrichtungsänderungskanal C zu bilden, und die Endabdeckungen **35** sind mit äußeren Umfangs-Führungsbereichen **35a**, die den Richtungsänderungskanal C in Verbindung mit den inneren Umfangs-Führungsbereichen **36d** bilden, ausgebildet. Das bedeutet, dass, wenn die Endabdeckungen **35** an dem Körperbereich **34** befestigt sind, der innere und der äußere Umfangs-Führungsbereich **36d** und **35a** so montiert werden, um dadurch die U-förmigen Rollen-Rollrichtungsänderungskanäle C an beiden Endbereichen zu bilden. Der endlose Zirkulationsdurchgangsweg ist durch den belasteten Rollen-Rolldurchgangsweg A, den Rückführdurchgangsweg B und die U-förmigen Richtungsänderungs-Durchgangswege C, wenn sie montiert sind, gebildet.

[0046] Entsprechend der Bewegung des bewegbaren Blocks **33** entlang der Führungsschiene **22** werden die Rollen **24**, **24**, --, **24** von einem Ende zu dem anderen Ende des belasteten Rollen-Rolldurchgangsweges A bewegt (gerollt), während sie mit der Last von dem bewegbaren Block **33** beaufschlagt werden, aufgenommen durch einen der Richtungsänderungskanäle C, geführt zu dem Rückführkanal B, und dann zurückgeführt zu einem Ende des belasteten Rollen-Rolldurchgangsweges A durch den anderen einen der Richtungsänderungskanäle C. In dieser Zirkulationsbewegung rollen die Rollen **24**, wobei die Last darauf aufgebracht wird, in dem belasteten Kugel-Rolldurchgangsweg A und Zirkulieren in den nicht belasteten Richtungsänderungskanälen C und den nicht belasteten Rückführkanal B. Allgemein bewegen sich die Rollen **24** unter einer relativ hohen Geschwindigkeit in dem belasteten Bereich und einer relativ niedrigen Geschwindigkeit in dem nicht belasteten Bereich. Gemäß der vorliegenden Erfindung werden die Distanzstücke **20** ausreichend elastisch in deren Vorschubrichtung deformiert, und eine der Rollen **24**, **24**, angeordnet an beiden Seiten des Distanzstücks **20**, kann relativ zu der anderen einen davon bewegt werden, wobei die Rollen **24** ohne Störung durch die Grenzbereiche zwischen dem belasteten Bereich und dem nicht belasteten Bereich in dem Endlos-Zirkulationsdurchgangsweg hindurchführen können, und, demzufolge, störungsfrei darin zirkuliert werden.

[0047] Fig. 4 und Fig. 5 stellen ein Distanzstück **20** dar, das mit der Linearrollbewegungsführungsvorrichtung **21**, dargestellt in Fig. 1, zum Beispiel, verbunden ist. Das Distanzstück **20** ist vorzugsweise aus einem synthetischen Harzmaterial über einen Spritzgieß-Vorgang, zum Beispiel, hergestellt. Jedes der Distanzstücke **20** ist zwischen den Rollen **24** angeordnet und ist mit gekrümmten Rückhalteflächen

28 an beiden Endbereichen in einer Vorschubrichtung (Richtung ① in Fig. 5) des Distanzstücks **20** ausgebildet. Die gekrümmte Rückhaltefläche besitzt eine Form entsprechend zu einer Umfangsform der Rolle **24**. Wenn die gekrümmten Rückhalteflächen **28** des Distanzstücks **20** gegen die Rollen **24** an beiden Endseiten anstoßen, stimmt die Mittellinie des Distanzstücks **20** mit der Linie, die die zentralen Bereiche der Rollen **24**, angeordnet an beiden Seiten davon, verbinden, überein. Das Distanzstück **20** besitzt eine Länge, normal zu der Vorschubrichtung, entsprechend zu der axialen Richtung der Rolle **24**, leicht geringer als die axiale Länge der Rolle, um so nicht in Kontakt mit dem Wandbereich des endlosen Rollenzirkulationsdurchgangswegs zu stehen, und das Distanzstück **20** besitzt auch eine Höhe leicht kleiner als ein Durchmesser der Rolle **24**.

[0048] Das Distanzstück **20** besitzt eine innere, hohle Struktur, die einen Hohlraum **29** so besitzt, dass eine der gekrümmten Rückhalteflächen **28** zu der anderen einen davon hin deformierbar ist, wobei sich der Hohlraum **29** in der Richtung parallel zu der axialen Richtung der Rolle **24** erstreckt. Das bedeutet, dass das Distanzstück **20** ein Paar von Rückhaltebereichen **20a** aufweist, von denen jedes die gekrümmte Rückhaltefläche **28**, gegenüberliegend zueinander in der Vorschubrichtung, und ein Paar von oberen und unteren Verbindungsbereichen **20b**, die die gepaarten Rückhaltebereiche **20a** mit dem Hohlraum **29** dazwischen verbinden, besitzt. Da die Verbindungsbereiche **20b** so ausgebildet sind, dass sie dünn sind, um so leicht gebogen zu werden, ist eine der gekrümmten Rückhalteflächen **28** elastisch zu der anderen einen davon hin deformiert.

[0049] Die Distanzstücke **20** der Struktur, die vorstehend erwähnt ist, und die Rollen **24** sind in dem endlosen Rollenzirkulationsdurchgangsweg in einer alternierenden Anordnung zueinander aufgenommen. Wenn die Distanzstücke **20** und die Rollen **24** darin montiert sind, ist, da die Distanzstücke **20** in dem Zustand eng in der Vorschubrichtung zusammengedrückt angeordnet sind, im Wesentlichen kein Raum oder Zwischenraum zwischen der Reihe der Rollen **24** und den Distanzstücken **20** und dem Wandbereich des endlosen Zirkulationsdurchgangswegs vorhanden. Dementsprechend wird jedes der Distanzstücke **20** fest zwischen den angrenzenden Rollen **24**, **24** an einer konstanten, vorbestimmten Position durch die Rückstellkraft des Distanzstücks **20** selbst festgeklemmt, und demzufolge ist dabei keine Gefahr vorhanden, dass die Rollen **24** in die Distanzstücke **20** während der Zirkulation davon eingreifen.

[0050] Wie Fig. 1 zeigt, rollen, wenn sich der Körperblock **36a** entlang der Führungsschiene **22** bewegt, die Rollen **24**, **24**, --, **24**, während sie mit der Last von dem bewegbaren Block **36a**, in dem belasteten Rollen-Rolldurchgangsweg A von einem Ende zu dem anderen Ende davon, beaufschlagt werden. Danach werden die Rollen **24** durch einen der Rollen-Richtungsänderungs-Durchgangswege C aufgenommen, dann zu dem Rückführ-Durchgangsweg B geführt und danach zu einem Ende des belasteten Rollen-Rolldurchgangswegs A mittels des anderen einen des Rollen-Richtungsänderungs-Kanals C zurückgeführt. In dieser Zirkulationsbewegung rollen die Rollen **24** mit dem belasteten Zustand in dem belasteten Bereich des belasteten Rollen-Rolldurchgangswegs A und Rollen mit dem nicht belasteten Zustand in dem nicht belasteten Bereich der Richtungsänderungs-Durchgangswege C und dem Rückführ-Durchgangsweg B. Allgemein rollen die Rollen **24** schnell in dem belasteten Bereich und langsam in dem nicht belasteten Bereich.

[0051] Gemäß dieser ersten Ausführungsform können, da die Distanzstücke **20** ausreichend elastisch in der Vorschubrichtung deformiert werden und eine der Rollen **24**, angeordnet an beiden Vorschubseiten des Distanzstücks **20**, relativ in Bezug auf die andere Eine der Rollen **24** bewegt werden kann, die Rollen **24** ohne Behinderung zwischen dem belasteten Bereich und dem nicht belasteten Bereich in dem endlosen Rollenzirkulationsdurchgangsweg bewegt werden.

[0052] Die Fig. 6 bis Fig. 8 stellen eine lineare Rollbewegungs-Führungsvorrichtung **31**, versehen mit einem Distanzstück gemäß einer zweiten Ausführungsform der vorliegenden Erfindung, dar.

[0053] Wie die Fig. 6 bis Fig. 8 zeigen, weist die Linearrollbewegungsführungsvorrichtung **31**, ähnlich der Vorrichtung **21** der früheren Ausführungsform, eine Führungsschiene **22**, einen bewegbaren Körperblock **33**, montiert mit der Führungsschiene **22**, um relativ entlang der Führungsschiene **22** bewegbar zu sein, eine Anzahl von Rollen **24**, **24**, --, **24** und eine Anzahl von Kugeln **25**, **25**, --, **25** auf, und dementsprechend sind entsprechende Bezugszeichen zu den Merkmalen entsprechend zu solchen der Führungsvorrichtung **21** hinzugefügt und die detaillierte Beschreibung davon kann hier weggelassen werden.

[0054] Der bewegbare Block **33** ist aus einem Körperbereich **34** und einem Paar von Endabdeckungen **35**, die miteinander mittels Schrauben, oder dergleichen, befestigt sind, aufgebaut. Der Körperbereich **34** weist einen Körperblock **36a** und geformte Produkte **36b** und **36c** auf, und die geformten Produkte **36b**, **36c** sind integral mit dem Körperblock **36a** durch Einspritzen eines geschmolzenen Harzes in eine Form, in der der Körperblock **36a** zuvor eingesetzt ist, mittels einem so genannten Einsetzgieß-Vorgang, gebildet.

[0055] Weiterhin besitzt der Körperbereich **34** einen horizontalen Bereich **36**, der zu der oberen Fläche der Führungsschiene **22** in einem montierten Zustand gegenüberliegt, und ein Paar von bilateralen Rand-(Schenkel)-Bereichen **37**, die sich nach unten von beiden Seitenenden des horizontalen Bereichs **36** erstrecken, um so zu den Seitenflächen der Führungsschiene **22** in dem montierten Zustand gegenüber zu liegen. Der horizontale Bereich **36** ist mit zwei Rollen-Rollnuten **34a**, **34a**, als belastete Rollen-Rollflächen, die den Rollen-Rollflächen **22a** der oberen Fläche der Führungsschiene **22** gegenüberliegen, ausgebildet. Die Randbereiche **37** sind mit oberen und unteren, belasteten Kugel-Rollnuten **34b**, **34b** entsprechend zu den Kugel-Rollnuten **22b**, **22b**, gebildet auf den Seitenflächen der Führungsschienen **22**, ausgebildet. Die Rollen-Rollflächen **22a** und die Rollen-Rollnuten **34a** bilden die belasteten Rollen-Rolldurchgangswege A in Kombination, und andererseits bilden die Kugel-Rollnuten **22b**, **22b** und die belasteten Kugel-Rollnuten **34b**, **34b** den belasteten Kugel-Rolldurchgangsweg A'.

[0056] Der horizontale Bereich **36** ist auch mit zwei Durchgangslöchern ausgebildet, die sich parallel zu den Rollen-Rollflächen **22a** der Führungsschiene **22** in der Längsrichtung des bewegbaren Blocks **33** erstrecken. Ringförmige Bereiche der Form-Produkte **36c**, **36c** sind in diese Durchgangslöcher integral eingesetzt, und die rohrförmigen Bereiche besitzen innere, hohle Bereiche, die als Rollen-Rückführkanäle B gebildet sind. Jeder der Randbereiche **37** ist auch mit zwei (vier insgesamt) Durchgangslöchern in jeder Seite, sich parallel zu den belasteten Kugel-Rollnuten **34b**, **34b** erstreckend, ausgebildet. Die rohrförmigen Bereiche des geformten Produkts **36c** sind in diese Durchgangslöcher integral eingesetzt, und die rohrförmigen Bereiche besitzen innere, hohle Bereiche, die als Kugel-Rückführ-Durchgangswege B' ausgebildet sind.

[0057] Wie Fig. 7 zeigt, ist das geformte Produkt **36b** integral mit der gesamten, inneren Oberfläche des Körperblocks **36a**, umfassend die untere Fläche des horizontalen Bereichs **36** und die innenseitigen Flächen der Randbereiche **37**, gebildet. Zu dem geformten Produkt **36b** sind Rollen-Rückhaltebereiche (Rückhalteeinrichtungen) **39** vorgesehen, um zu verhindern, dass die Rollen **24** aus den belasteten Rollen-Rolldurchgangswegen A zu dem Zeitpunkt eines Herausziehens des bewegbaren Blocks **33** von der Führungsschiene **22** herauskommen, und dort sind auch Kugel-Rückhaltebereiche (Rückhalteeinrichtungen) **40** vorgesehen, um zu verhindern, dass die Kugeln **25** von dem belasteten Kugel-Rolldurchgangsweg A' zu der Herausziehzeit des bewegbaren Blocks heraus kommen.

[0058] Wie Fig. 8 zeigt, sind bogenförmige, innere Umfangs-Führungsbereiche **36d**, **36d** an beiden Endbereichen des Körperblocks **36a** so gebildet, um nach außen vorzustehen, um dadurch Rollrichtungsänderungs-Durchgangswege C zu dem geformten Produkt **36c** zu bilden, und an den Endabdeckungen **35** sind äußere Umfangs-Führungsbereiche **35a**, **35a** zum Bilden der Rollen-Richtungsänderungs-Durchgangswege C in Kombination mit den inneren Umfangs-Führungsbereichen **36d**, **36d** gebildet, wenn die Endabdeckungen **35**, **35** an dem Körperblock **36a** befestigt sind. Wie vorstehend erwähnt ist, ist der Endlos-Rollenzirkulationsdurchgangsweg so durch die Kombination (Montage) des belasteten Rollen-Rolldurchgangswegs A, der U-förmigen Rollen-Richtungsänderungs-Durchgangswege C und des Rückführ-Durchgangswegs B gebildet.

[0059] Gemäß der Linearrollbewegungsführungsvorrichtung **31** der vorliegenden Ausführungsform, die den vorstehenden Aufbau besitzt, werden, wenn die Rollen **24** zirkuliert werden, Distanzstücke **45** zweidimensional in deren Richtungen geändert. Das bedeutet, dass die Rollen **24** rollen und in den Rollrichtungen von dem linearen, belasteten Rolldurchgangsweg A, dem U-förmigen, eine Richtung ändernden Durchgangsweg C, dem Rückführ-Durchgangsweg B und dem U-förmigen anderen Richtungsänderungs-Durchgangswegs C geändert werden.

[0060] Dabei ist eine Führungsnut **43** (siehe Fig. 6–Fig. 8) an der inneren Umfangsseite des Endlos-Rollenzirkulationsdurchgangswegs zum Aufnehmen von vorstehenden Platten **41** der Distanzstücke **45** gebildet, und, in diesem Zusammenhang, besitzt die Führungsnut **43** eine Breite leicht größer als eine Dicke der vorstehenden Platte **41**. Wenn die Rollen **24**, d.h. die Distanzstücke **45**, in dem Endlos-Rollenzirkulationsdurchgangsweg bewegt werden, bewegen sich die vorstehenden Platten **41** der Distanzstücke **45** entlang der Führungsnut **43**.

[0061] Fig. 9 und Fig. 10 stellen die Distanzstücke **45** der zweiten Ausführungsform, die in die Linearrollbewegungsführungsvorrichtung **31** eingesetzt werden, dar.

[0062] Das Distanzstück **45** ist auch über den Formungsvorgang eines Harzes wie in der ersten Ausführungsform, wie dies vorstehend erwähnt ist, gebildet. Das Distanzstück **45** ist mit gekrümmten Rückhalteflächen **42** an deren beiden Enden in der Vorschubrichtung davon gebildet, wobei die Rückhalteflächen **42** eine Form entsprechend zu der äußeren Umfangsform der Rolle **24** besitzen. Das Distanzstück **45** ist mit einem inneren, hohlen Bereich (Hohlraum) **46** ausgebildet, der sich in einer Richtung parallel zu der axialen Richtung der Rolle **24** erstreckt, so dass eine der gekrümmten Rückhalteflächen **42** elastisch zu der anderen davon hin deformierbar ist, wenn ein Druck aufgebracht wird.

[0063] Weiterhin ist, wie kurz vorstehend erwähnt ist, das Distanzstück **45** mit der vorstehenden Platte

41, unterschiedlich gegenüber dem Distanzstück **20** in der früheren Ausführungsform, ausgebildet, sich nach außen (nach oben) in einer Richtung normal zu der axialen Richtung der Rolle **24** erstreckend. Die vorstehende Platte **41** ist an im Wesentlichen dem zentralen Bereich einer der Verbindungsplatten **45a**, die beide gekrümmten Rückhalteflächen verbindet, gebildet. Der vorstehende Endbereich der vorstehenden Platte **41** ist in die Führungsnut **43**, gebildet auf der inneren Umfangsfläche des Endlos-Rollenzirkulationsdurchgangswegs, eingesetzt. Weiterhin ist es bevorzugt, dass der vorstehende Endbereich der vorstehenden Platte **41** eine kreisförmige, äußere Form für ein einfaches Einsetzen und eine störungsfreie Zirkulation in der Führungsnut **43** besitzt.

[0064] Das Distanzstück **45** dieser zweiten Ausführungsform kann im Wesentlichen dieselben Funktionen wie solche der ersten Ausführungsform erreichen, und zusätzlich kann, gemäß dem Distanzstück **45** der zweiten Ausführungsform, da die vorstehenden Platten **41** der Distanzstücke **45** entlang des vorbestimmten Wegs in der Führungsnut **43** geführt werden können, die Rollen **24**, getragen durch die Distanzstücke **45**, störungsfrei und stabil in dem Endlos-Rollenzirkulationsdurchgangsweg bewegt und zirkuliert werden, ohne in einer mäanderförmigen Art und Weise, zum Beispiel, zu rollen. Insbesondere kann, da die Distanzstücke **45** nicht in der mäanderförmigen Art und Weise in der Rollen-Axialrichtung bewegt werden, die Kollision der axialen Endflächen der Distanzstücke **45** gegen den Wandbereich des endlosen Rollenzirkulationsdurchgangswegs effektiv verhindert werden.

[0065] Die Distanzstücke **20** und **45** gemäß der vorliegenden Erfindung können, anders als die Linearrollbewegungsführungsvorrichtungen **21** und **33**, die jeweils vorstehend erwähnt sind, bei einer Rollen-Schraub- bzw. Spindelvorrichtung und einer Rollen-Keilwellenvorrichtung angewandt werden, wobei die letztere eine Keilwelle als ein Führungselement und ein Gleitelement als ein äußeres, zylindrisches Element, befestigt so, um zu der Keilwelle über eine Anzahl von Rollen bewegbar zu sein, aufweist.

Patentansprüche

1. Distanzstück (**45**) für eine Linearbewegungsvorrichtung (**31**), das zwischen Rollen (**24**), angeordnet in einem endlosen Zirkulationsdurchgangsweg der Linearbewegungsvorrichtung, zwischengefügt werden soll, wobei das Distanzstück einen Körperbereich besitzt, der gekrümmte Rückhalteflächenbereiche (**20a**, **42**) aufweist, die eine Form entsprechend zu einer Umfangsform der Rolle (**24**) aufweisen, um die Rollen an beiden Endabschnitten davon in einer Vorschubrichtung des Distanzstücks zu tragen, wenn es sich in dem endlosen Zirkulationsdurchgangsweg bewegt, wobei der Körperbereich weiterhin ein Paar eines oberen und unteren Seitenflächenbereichs (**20b**, **45a**), die die gekrümmten Rückhalteflächenbereiche verbinden, aufweist, und ein innerer, hohler Bereich (**46**) in dem Körperbereich des Distanzstücks durch die gekrümmten Rückhalteflächenbereiche und das Paar des oberen und unteren Seitenflächenbereichs (**20b**, **45a**) definiert ist, wobei sich der innere, hohle Bereich in einer Richtung im Wesentlichen parallel zu einer axialen Richtung der Rolle erstreckt so, dass die gekrümmten Rückhalteflächenbereiche elastisch zueinander hin in der Vorschubrichtung deformierbar sind.

2. Distanzstück (**45**) für eine Linearbewegungsvorrichtung (**31**) nach Anspruch 1, die weiterhin ein vorstehendes Teil (**41**), gebildet an einem des oberen und des unteren Seitenflächenbereichs (**25b**, **45a**) des Körperbereichs, aufweist, um sich so in einer Richtung senkrecht zu einer axialen Richtung der Rolle (**24**) zu erstrecken.

3. Distanzstück (**45**) für eine Linearbewegungsvorrichtung (**31**) nach Anspruch 2, wobei das vorstehende Teil ein vorstehendes Ende besitzt, das eine runde Form besitzt.

4. Distanzstück (**45**) für eine Linearbewegungsvorrichtung (**31**) nach einem der Ansprüche 1 bis 3, wobei der Körperbereich des Distanzstücks aus einem einzelnen, elastischen Material gebildet ist.

5. Linearbewegungsvorrichtung (**31**), die aufweist:
ein Führungsschienenelement (**2**), ausgebildet mit einer Rollenfläche;
ein Gleitelement (**3**), befestigt so, um relativ zu dem Führungsschienenelement, ausgebildet mit einem Rollenzirkulationsdurchgangsweg, umfassend eine belastete Rollenrollnut (A), die der Rollenrollfläche des Führungsschienenelements gegenüberliegt, wenn sie montiert ist, bewegbar zu sein, wobei das Gleitelement mit einer Führungsnut (**43**), die entlang des Rollenzirkulationsdurchgangswegs gebildet ist, versehen ist;
eine Anzahl von Rollen (**24**), angeordnet in dem Rollenzirkulationsdurchgangsweg so, um darin in Übereinstimmung mit der relativen Bewegung des Gleitelements in Bezug auf das Führungsschienenelement zu zirkulieren; und
eine Anzahl von Distanzstücken (**45**), angeordnet zwischen den Rollen in einer alternierenden Art und Weise, wobei jedes der Distanzstücke gemäß einem der vorhergehenden Ansprüche ausgebildet ist.

Beschreibung

Gebiet der Erfindung und Stand der Technik

1. Gebiet der Erfindung

[0001] Die Erfindung betrifft eine Universalführungsvorrichtung, die in Gleitabschnitten verschiedener Werkzeugmaschinen, Güter fördernder Systeme und dergleichen zum Einsatz kommt und in der Lage ist, einen beweglichen Gegenstand oder ein bewegliches Material entlang einer Förderstrecke zu führen, die sowohl geradlinige wie auch krummlinige Bereiche umfasst.

2. Stand der Technik

[0002] Sind in einer Fabrik beispielsweise in einer Fertigungsstraße oder dergleichen sämtliche Verarbeitungsstationen linear angeordnet, so ist dies problemfrei. Es kann jedoch in Abhängigkeit von den räumlichen Gegebenheiten in der die Maschinen beherbergenden Fabrik oder in Abhängigkeit von den Verarbeitungsgegebenheiten an den einzelnen Verarbeitungsstationen notwendig sein, die Förderrichtung der zu verarbeitenden Materialien zwischen zwei benachbarten Verarbeitungsstationen zu ändern. In diesem Fall ist, um eine Änderung der Förderrichtung vorzunehmen, die Verwendung eines Palettenwechslers oder dergleichen üblich. Nachteiligerweise erfordert dies zusätzlichen Raum und zieht zusätzliche Kosten bedingt durch die Aufstellung des Palettenwechslers oder dergleichen nach sich.

[0003] Bekannte auf einen Palettenwechsler verzichtende Mittel zur Änderung der Förderrichtung von Materialien oder Gegenständen umfassen Universalführungsvorrichtungen (wie in den japanischen Patentveröffentlichungen JP63293319A (US4,844,624A) und JP6050333A (US5,308,170A) beschrieben, die sämtliche Merkmale des Oberbegriffes von Anspruch 1 offenbaren), die in der Lage sind, Materialien entlang einer Strecke aus sowohl geradlinigen wie auch krummlinigen Abschnitten kontinuierlich zu führen, sowie krummlinige Führungsvorrichtungen (wie in der japanischen Patentveröffentlichung JP63186028A beschrieben), die in der Lage sind, Materialien entlang einer ringförmigen Strecke kontinuierlich zu führen.

[0004] Die Universalführungsvorrichtungen und die krummlinigen Führungsvorrichtungen umfassen jeweils eine Bahnschiene, einen Gleiter und eine Mehrzahl von Kugeln. Die Schiene bildet sich in Längsrichtung erstreckende Flächen aus, an denen die Kugeln rollen. Der Gleiter ist derart angebracht, dass er die Schiene überspannt. Lastrollflächen gegenüber den Rollflächen der Schiene und eine Endlosringstrecke für die Kugeln sind an und in dem Gleiter ausgebildet. Die Endlosringstrecke enthält die Lastrollflächen. Die Kugeln rollen in der Endlosringstrecke des Gleiters und zwischen den Rollflächen der Schiene, wobei die Lastrollflächen des Gleiters eine Last tragen. Der Gleiter bewegt sich entsprechend der Rollbewegung der Kugeln entlang der Schiene.

[0005] Bei den bekannten Universalführungsvorrichtungen ist jede Lastrollfläche des Gleiters in geradlinige Lastbereiche, die linear ausgebildet sind, und krummlinige Lastbereiche, die in Entsprechung zur Krümmung der Schiene als Bogen ausgebildet sind, unterteilt. In jedem geradlinigen Lastbereich der Schiene wird die auf den Gleiter wirkende Last von denjenigen Kugeln getragen, die in dem geradlinigen Lastbereich rollen. In jedem krummlinigen Bereich wird die Last von denjenigen Kugeln getragen, die in dem krummlinigen Bereich rollen. Dies führt dazu, dass sich auch für den Fall, dass geradlinige und krummlinige Bereiche an ein und derselben Bahnschiene vorhanden sind, der Gleiter entlang der Schiene durch die geradlinigen und krummlinigen Bereiche kontinuierlich bewegen kann.

[0006] Bei der genannten krummlinigen Führungsvorrichtung ist die Bahnschiene als Bogen mit einer gegebenen Krümmung ausgebildet. Die Lastrollfläche des Gleiters ist in Entsprechung zur Krümmung der Schiene als Bogen ausgebildet. Sämtliche zwischen der Lastrollfläche des Gleiters und der Rollfläche der Schiene befindlichen Kugeln rollen, während sie die an dem Gleiter anliegende Last tragen. Infolgedessen kann der Gleiter eine krummlinige Bewegung entlang der Schiene ausführen.

[0007] Bei derartigen herkömmlichen Universalführungsvorrichtungen und krummlinigen Führungsvorrichtungen ist die Lastrollnut beziehungsweise Lastrolllaufbahn in dem Gleiter in Entsprechung zur Krümmung der Bahnschiene als Bogen ausgebildet, um eine Bewegung des Gleiters durch die krummlinigen Bereiche der Schiene zu ermöglichen. Es ist daher notwendig, die Lastrollfläche in Entsprechung zur Krümmung der Schiene herzustellen. Es ist jedoch nicht möglich, die Gleiter herkömmlicher, auf dem Markt erhältlicher und in Massenfertigung hergestellter linearer Führungsvorrichtungen direkt einzusetzen, was die Herstellungskosten nach oben treibt. Darüber hinaus bedarf jede Bahnschiene mit einer anderen Krümmung eines anderen Gleiters. Herstellung und Handhabung der Gleiter sind daher aufwändig.

[0008] Wird die Lastrollfläche eines Gleiters in Bogenform ausgebildet, so ist die Krümmungsrichtung des krummlinigen Bereiches der Bahnschiene auf eine Richtung, nämlich entweder links oder rechts, beschränkt. Obwohl es möglich ist, Materialien und Gegenstände auf einer Ringbahn zu befördern, ist es nicht möglich, Materialien entlang einer Schiene mit zwei krummlinigen Bereichen zu fördern, die in verschiedene Richtungen gekrümmt sind, wie dies beispielsweise bei einer S-förmigen Schiene der Fall ist.

[0009] Demgegenüber treten an einer Strecke zwischen zwei benachbarten Bearbeitungsstationen in einer Fertigungsstraße für den Fall, dass Materialien transportiert werden, keinerlei Probleme auf. Es wird davon ausgegangen, dass die Fähigkeit, sehr große Lasten zu tragen, in den krummlinigen Bereichen der Schiene nicht vorhanden sein muss. Dennoch muss während des Fertigungsvorgangs eine während der Bearbeitung auf ein Material einwirkende Kraft von der Führungsvorrichtung verlässlich aufgenommen werden. Geradlinige Bereiche der Schiene müssen die Fähigkeit aufweisen, größere Lasten zu tragen, als dies bei krummlinigen Bereichen der Fall ist. Bei der vorstehend genannten herkömmlichen Universalführungsvorrichtung ist die an dem Gleiter ausgebildete Lastrollfläche in geradlinige und krummlinige Lastbereiche unterteilt. Daher weisen die geradlinigen Bereiche der Schiene in geringerem Maße die Fähigkeit auf, Lasten zu tragen. Infolgedessen kann eine bei der Bearbeitung auf Materialien einwirkende Kraft nicht in ausreichendem Maße aufgenommen werden.

[0010] Werden Materialien in der Praxis unter Verwendung derartiger Universalführungsvorrichtungen befördert, so ist der Einbau einer sich bewegenden Tischvorrichtung zwischen zwei oder mehreren Universalführungsvorrichtungen erforderlich, um die Materialien stabil zu fördern. Insbesondere sind zwei Bahnschienen parallel zueinander angeordnet. Mehrere Gleiter sind auf jeder Bahnschiene angebracht. Ein Tisch ist derart angeordnet, dass er sämtliche Gleiter überspannt. Die zu fördernden Materialien sind auf diesem Tisch angeordnet.

[0011] Wird der Tisch nur durch einen linearen Bereich oder nur durch einen krummlinigen Bereich gefördert, so treten für den Fall, dass sämtliche Gleiter direkt an dem Tisch angebracht sind, keinerlei Probleme auf. Der Tisch kann gleichmäßig bewegt werden. Wird der Tisch jedoch kontinuierlich aus einem krummlinigen Bereich in einen geradlinigen Bereich oder umgekehrt bewegt, so bestehen aufgrund des Vorhandenseins anderer Gleiter für den Fall, dass die Gleiter direkt an ein und demselben Tisch angebracht sind, Beschränkungen mit Blick auf die Ausgestaltung des Gleiters gegenüber der Bahnschiene. Hierdurch wird es schwierig, den Tisch gleichmäßig zu bewegen. Entsprechend ist es für den Fall, dass mehrere Universalführungsvorrichtungen mit vorstehend beschriebenem Aufbau verwendet werden, um die sich bewegende Tischvorrichtung zu bilden, unmöglich, die Gleiter direkt an dem Tisch anzubringen.

[0012] Eingedenk des vorstehend geschilderten Problems wurde die vorliegende Erfindung gemacht. Es ist Aufgabe der vorliegenden Erfindung, eine Universalführungsvorrichtung bereitzustellen, bei der wenigstens bei den bevorzugten Ausführungsbeispielen Gleiter, die bislang in herkömmlichen linearen Führungsvorrichtungen verwendet wurden, eingesetzt werden können, und bei der nicht jeweils ein anderer Gleiter für eine Bahnschiene mit anderem Radius verwendet werden muss, wodurch die Herstellung vorzugsweise zu niedrigeren Kosten erfolgen kann, als dies bislang der Fall ist.

[0013] Eine weitere Aufgabe wenigstens bevorzugter Ausführungsbeispiele der Erfindung besteht darin, eine Universalführungsvorrichtung bereitzustellen, bei der sich Gleiter auch dann kontinuierlich durch zwei krummlinige Bereiche einer Bahnschiene entlang der Schiene bewegen können, wenn die beiden krummlinigen Bereiche in verschiedene Richtungen gekrümmt sind, und bei der sich die Gleiter kontinuierlich von einem geradlinigen Bereich in einen krummlinigen Bereich oder umgekehrt bewegen können, ohne dass die Schiene die Fähigkeit verlieren würde, eine Last in dem geradlinigen Bereich zu tragen, und dies auch dann, wenn die Schiene sowohl geradlinige wie auch krummlinige Bereiche umfasst.

[0014] Eine weitere Aufgabe wenigstens bevorzugter Ausführungsbeispiele der Erfindung besteht in der Bereitstellung einer sich bewegenden Tischvorrichtung mit mehreren parallelen Bahnschienen und mehreren an jeder Bahnschiene angebrachten Gleitern, wobei sich die bewegliche Tischvorrichtung dadurch auszeichnet, dass eine gleichmäßige Bewegung der Gleiter auch dann sichergestellt ist, wenn der Tisch von vier oder mehr Gleitern getragen wird.

[0015] Zur Lösung der vorstehend aufgeführten Aufgaben ist gemäß einem Aspekt der Erfindung eine erfindungsgemäße Universalführungsvorrichtung vorgesehen, die umfasst: eine Bahnschiene mit einem geradlinigen Bereich und einem krummlinigen Bereich, der als Bogen mit einem gegebenen Krümmungsradius ausgebildet ist, sowie mit Kugelrollflächen an ihren beiden Seitenflächen, wobei sich die Kugelrollflächen in Längsrichtung erstrecken; einen sattelförmigen Querschnitt aufweisenden Gleiter, der derart angebracht ist, dass er die Bahnschiene überspannt; Lastrollflächen, die an dem Gleiter ausgebildet und jeweils gegenüber den Rollflächen der Schiene angeordnet sind; sowie eine Endlosringstrecke für eine Anzahl von Kugeln. Die Ringstrecke ist an dem Gleiter ausgebildet und enthält die Lastrollflächen. Die zahlreichen Kugeln tragen eine Last zwischen jeder Rollfläche der Bahnschiene und jeder Lastrollfläche des Gleiters. Sämtliche an dem Gleiter ausgebildeten Lastrollflächen sind linear ausgebildet. Die Breite des krummlinigen Bereiches der Bahnschiene ist im Vergleich zum geradlinigen Bereich der Schiene kleiner gewählt.

[0016] Bei der erfindungsgemäßen Universalführungsvorrichtung sind die an dem Gleiter ausgebildeten Lastrollflächen nicht als Bogen entsprechend der Krümmung des krummlinigen Bereiches der Bahnschiene ausgebildet. Die Lastrollflächen sind vielmehr in Entsprechung zu den Rollflächen des geradlinigen Bereiches der Bahnschiene linear ausgebildet. Bei einer derartigen Anordnung ist der krummlinige Bereich der Schiene im Vergleich zum geradlinigen Bereich der Schiene schmäler ausgebildet. Daher kann für den Fall, dass die Rollflächen der Schiene die Form eines Bogens aufweisen, und die Lastrollflächen des Gleiters linear sind, der Gleiter mit den krummlinigen Bereichen der Schiene in Eingriff treten und sich entlang der krummlinigen Bereiche problemlos bewegen.

[0017] Bewegt sich der Gleiter durch den krummlinigen Bereich der Bahnschiene, so werden die Kugeln zwischen den in Längsrichtung entlang der Schiene ausgebildeten bogenförmigen Rollflächen und den an dem Gleiter ausgebildeten linearen Lastrollflächen zusammengeschoben und rollen entlang der Lastrollflächen, wobei sie die Last tragen. Mit Blick auf die Mehrzahl der an den Lastrollflächen rollenden Kugeln tragen nur einige der Kugeln die Last zwischen den Rollflächen der Schiene und den Lastrollflächen des Gleiters.

[0018] Bei der erfindungsgemäßen Universalführungsvorrichtung sind die an dem Gleiter ausgebildeten Lastrollflächen nicht als Bogen, sondern linear ausgebildet. Aus diesem Grunde können die Gleiter linearer Führungsvorrichtungen unverändert verwendet werden. Darüber hinaus kann auf den Vorgang der maschinellen Ausbildung der Lastrollfläche als Bogen entsprechend der Krümmung der Bahnschiene verzichtet werden. Es ist daher möglich, eine Universalführungsvorrichtung zu vergleichsweise niedrigen Kosten herzustellen. Darüber hinaus weisen die linear ausgebildeten Lastrollflächen keine Vorzugsrichtung auf. Infolgedessen kann sich sogar für den Fall, dass zwei krummlinige Bereiche mit verschiedenen Krümmungsrichtungen an der Schiene vorhanden sind, der Gleiter kontinuierlich durch diese krummlinigen Bereiche bewegen.

[0019] Darüber hinaus liegen bei der vorstehend beschriebenen Universalführungsvorrichtung sämtliche an den Lastrollflächen des Gleiters rollenden Kugeln an den Rollflächen der Bahnschiene innerhalb des geradlinigen Bereiches der Schiene an. Aus diesem Grunde wird die Fähigkeit des Gleiters, eine Last zu tragen, nicht beeinträchtigt, was im Gegensatz zu demjenigen Fall ist, in dem lediglich einige Kugeln an den Rollflächen in einem krummlinigen Bereich anliegen. Liegen große Lasten an dem Gleiter an, so können die Lasten in ausreichendem Maße getragen werden.

[0020] Bei derartigen Anordnungen berühren für den Fall, dass die Kugelrollflächen an der Bahnschienenseite an den Flächen der Schiene ausgebildet sind, die eine Reihe bildenden und an der Lastrollfläche des Gleiters rollenden Kugeln die bogenförmige Rollfläche an der Schienenseite nicht gleichzeitig. Daher kann die Rollfläche auf gleiche Weise ausgebildet sein, wie dies bei der Rollfläche einer krummlinigen Führungsvorrichtung aus dem Stand der Technik der Fall ist, ohne dass irgendein besonderer Bearbeitungsvorgang von Nöten wäre. Darüber hinaus kann diese Bahnschiene einfach hergestellt werden, da eine Fläche der Schiene und die darauf ausgebildete bogenförmige Rollfläche gleichzeitig geschliffen werden können. Ist jedoch eine nach oben weisende Rollfläche an der oberen Fläche einer Bahnschiene ausgebildet, so bedarf diese Rollfläche einer speziellen maschinellen Bearbeitung. Insbesondere ist bei einigen Ausführungsbeispielen eine nach unten weisende Lastrollfläche linear an dem Gleiter in zu der nach oben weisenden Rollfläche der Bahnschiene entgegengesetzter Ausrichtung ausgebildet. Infolgedessen muss die Breite der nach oben weisenden Rollfläche derart gewählt sein, das die eine Reihe bildenden und an der nach unten weisenden Rollfläche des Gleiters rollenden Kugeln die nach oben weisende Fläche gleichzeitig berühren.

[0021] Bei der erfindungsgemäßen Universalführungsvorrichtung kann sich der Gleiter sowohl durch die geradlinigen wie auch durch die krummlinigen Bereiche der Bahnschiene frei bewegen. Setzt sich die Schiene daher ausschließlich aus krummlinigen Bereichen zusammen, so kann sich der Gleiter entlang der ringförmigen Schiene bewegen. Dies bedeutet mit Blick auf die krummlinigen Bereiche der Schiene, dass die Universalführungsvorrichtung entsprechend der vorliegenden Erfindung als krummlinige Führungsvorrichtung betrachtet werden kann.

[0022] Wie vorstehend erwähnt, weisen die geradlinigen und die krummlinigen Bereiche der Bahnschiene der Universalführungsvorrichtung der vorliegenden Erfindung unterschiedliche Breiten auf. Bei bevorzugten Ausführungsbeispielen ist daher das Bereitstellen eines Übergangsschienenabschnittes vorteilhaft, der die geradlinigen und die krummlinigen Bereiche der Schiene derart verbindet, dass die Breite der Schiene in dem Übergangsschienenabschnitt kontinuierlich variiert.

[0023] Darüber hinaus kann eine sich bewegende Tischvorrichtung unter Verwendung der Universalführungsvorrichtungen mit vorstehend geschildertem erfindungsgemäßem Aufbau bereitgestellt werden.

[0024] Insbesondere werden mehrere Bahnschienen parallel zueinander an einem festen Abschnitt, so beispielsweise an einem Sockel oder einem Fundament, angebracht. Ein Tisch wird derart angebracht, dass er Gleiter überspannt, die sich an diesen

Schienen bewegen. Sind zwei oder mehr Gleiter an jeder Schiene angebracht, und sind sämtliche Gleiter direkt an demselben Tisch angebracht, so können Schwierigkeiten bei der gleichmäßigen Bewegung des Tisches zwischen den geradlinigen und den krummlinigen Bereichen der Schiene, wie vorstehend erläutert, auftreten.

[0025] Eingedenk dessen werden erste und zweite Bahnschienen parallel zueinander angeordnet. Mehrere Gleiter sind an diesen Schienen angeordnet. Vorzugsweise ist eine feste Platte derart angeordnet, dass sie einen an der ersten Schiene angeordneten Gleiter und einen an der zweiten Schiene angeordneten Gleiter derart überspannt, dass die beiden Gleiter gekoppelt sind. Eine weitere Festplatte überbrückt einen an der erste Schiene angeordneten Gleiter und einen an der zweiten Schiene angeordneten Gleiter, und so weiter. Vorzugsweise ist der Tisch derart angebracht, dass er gegenüber den festen Platten drehbar ist. Ist die sich bewegende Tischvorrichtung auf diese Weise aufgebaut, so gilt sogar für den Fall, dass der Tisch von vier Gleitern getragen wird, dass die erste feste Platte, die die erste Reihe von Gleitern (in Bewegungsrichtung vorauseilend) überspannt, und die zweite feste Platte, die die zweite Reihe von Gleitern überspannt, derart drehen, dass die Gleiter in tangentialer Richtung der Schienen ausgerichtet sind. Der Abstand zwischen den Gleitern an den Schienen ist variabel gewählt. Aus diesem Grunde können sich die Gleiter gleichmäßig bewegen.

[0026] Darüber hinaus kann sich der Tisch gleichmäßig zwischen den geradlinigen und den krummlinigen Bereichen der Schiene dadurch bewegen, dass die ersten und zweiten Schienen parallel zueinander angeordnet sind, dass mehrere Gleiter an jeder Schiene angeordnet sind, und dass der Tisch derart angebracht ist, dass er gegenüber den Gleitern drehbar ist. Bewegen sich in diesem Aufbau die Gleiter durch die krummlinigen Bereiche der Schiene, so drehen sie in beliebige Richtungen, um sich selbst in tangentiale Richtung der Schienen auszurichten. Dies ermöglicht eine gleichmäßige Bewegung der Gleiter.

[0027] Wie beschrieben, müssen bei den Universalführungsvorrichtungen entsprechend wenigstens den bevorzugten Ausführungsbeispielen der vorliegenden Erfindung, die an den Gleitern ausgebildeten Lastrollflächen nur linear und nicht bogenförmig ausgebildet werden. Aus diesem Grunde können die verschiedensten auf dem Markt erhältlichen linearen Führungsvorrichtungen unverändert verwendet werden. Darüber hinaus ist eine Herstellung der Lastrollflächen in Entsprechung zur Krümmung der Schienen nicht erforderlich. Daher können die Gleiter einfach und kostengünstig hergestellt werden.

[0028] Da die an den Gleitern ausgebildeten Lastrollflächen keine Vorzugsrichtung aufweisen, können sich für den Fall, dass jede Bahnschiene zwei krummlinige Bereiche mit verschiedenen Krümmungsrichtungen aufweist, die Gleiter kontinuierlich entlang der Schiene durch die krummlinigen Bereiche bewegen. So können beispielsweise Materialien frei und mit hohem Freiheitsgrad entlang einer Schiene (die beispielsweise aus einer Kombination aus geradlinigen Abschnitten und krummlinigen Abschnitten zusammengesetzt ist, wie dies beispielsweise bei einer S-förmigen Schiene der Fall ist) bewegt werden.

[0029] Da die an den Gleitern ausgebildeten Lastrollflächen linear sind, liegen sämtliche an den Lastrollflächen rollenden Kugeln an der Schiene in den geradlinigen Bereichen an und tragen die Last. Daher weisen die Gleiter in ausreichendem Maße die Fähigkeit auf, die Last in diesen geradlinigen Bereichen zu tragen. Treten an der Schiene sowohl geradlinige wie auch krummlinige Abschnitte auf, so können sich die Gleiter kontinuierlich durch die linearen und die krummlinigen Bereiche bewegen, ohne dass die Fähigkeit der Schiene verloren ginge, die Last in den geradlinigen Bereichen zu tragen.

[0030] Weitere Aufgaben und Merkmale der Erfindung erschließen sich im Laufe der nachfolgenden Beschreibung derselben.

[0031] Ausführungsbeispiele der Erfindung werden nachstehend beispielhalber anhand der begleitenden Zeichnung beschrieben, die sich wie folgt zusammensetzt.

[0032] Fig. 1 ist eine Skizzenansicht einer Universalführungsvorrichtung entsprechend einem ersten Ausführungsbeispiel der vorliegenden Erfindung.

[0033] Fig. 2 ist eine perspektivische Ansicht eines Gleiters des in Fig. 1 gezeigten geradlinigen Führungsschienenabschnittes.

[0034] Fig. 3 ist ein im Querschnitt genommener Frontaufriss des Gleiters und des in Fig. 2 gezeigten geradlinigen Führungsschienenabschnittes, wobei der Gleiter an der Schiene angeordnet ist.

[0035] Fig. 4 ist eine im Querschnitt genommene Skizzenansicht des Gleiters und der in Fig. 2 und Fig. 3 gezeigten geradlinigen Führungsschiene, wobei gezeigt ist, wie die Kugeln rollen und entlang einer Ringstrecke umlaufen, wenn sich der Gleiter entlang der Schiene bewegt.

[0036] Fig. 5 ist ein im Querschnitt genommener Frontaufriss ähnlich demjenigen von Fig. 3, wobei jedoch der Gleiter an einem krummlinigen Führungsschienenabschnitt angeordnet ist.

[0037] Fig. 6 ist eine im Querschnitt genommene

Skizzenansicht des Gleiters und des in Fig. 5 gezeigten krummlinigen Führungsschienenabschnittes, wobei gezeigt ist, wie die Kugeln entlang der Ringstrecke rollen, wenn sich der Gleiter entlang der Schiene bewegt.

[0038] Fig. 7 ist eine fragmentarische Skizzenansicht einer an der oberen Fläche eines krummlinigen Führungsschienenabschnittes ausgebildeten Rollfläche, wobei gezeigt ist, wie die Kugeln an der Rollfläche rollen.

[0039] Fig. 8 ist ein vergrößerter Querschnitt einer an der oberen Fläche eines krummlinigen Führungsschienenabschnittes ausgebildeten Rollfläche und einer Lastrollfläche eines Gleiters, wobei gezeigt ist, wie die Kugeln zwischen der Rollfläche an der Schiene und der Lastrollfläche des Gleiters rollen.

[0040] Fig. 9 ist eine Skizzenansicht einer Universalführungsvorrichtung, die dadurch hergestellt werden kann, dass eine Kombination aus geradlinigen Führungsschienenabschnitten und krummlinigen Führungsschienenabschnitten entsprechend dem ersten Ausführungsbeispiel gebildet wird.

[0041] Fig. 10(a) und Fig. 10(b) sind Skizzenansichten S-förmiger Schienen, wobei jede aus zwei getrennten Führungsschienenabschnitten besteht.

[0042] Fig. 11 ist eine fragmentarische Skizzenansicht eines Übergangsschienenabschnittes entsprechend dem ersten Ausführungsbeispiel der Erfindung.

[0043] Fig. 12 ist eine fragmentarische vergrößerte Skizzenansicht eines Abschnittes A von Fig. 11.

[0044] Fig. 13 ist eine vergrößerte Skizzenansicht eines Abschnittes B von Fig. 11.

[0045] Fig. 14 ist eine im Querschnitt genommene Frontansicht einer Universalführungsvorrichtung entsprechend einem zweiten Ausführungsbeispiel der Erfindung.

[0046] Fig. 15 ist ein vergrößerter Querschnitt von Hauptabschnitten der in Fig. 14 gezeigten krummlinigen Führungsschienenabschnitte.

[0047] Fig. 16 ist eine Querschnittsansicht der in Fig. 14 und Fig. 15 gezeigten krummlinigen Führungsschienenabschnitte, wobei der Schienenabschnitt an beiden Seitenflächen derart geschliffen wurde, dass er eine bestimmte Breite aufweist.

[0048] Fig. 17 ist eine fragmentarische Skizzenansicht einer sich bewegenden Tischvorrichtung, die ein drittes Ausführungsbeispiel der Erfindung darstellt, wobei bei der sich bewegenden Tischvorrichtung eine Universalführungsvorrichtung entsprechend der Erfindung zum Einsatz kommt.

[0049] Fig. 18 ist eine Querschnittsansicht bezüglich der Linie XVIII-XVIII von Fig. 17.

[0050] Fig. 19 ist eine perspektivische Ansicht eines Drehlagers, das bei der in Fig. 17 und Fig. 18 gezeigten sich bewegenden Tischvorrichtung verwendet wird.

[0051] Fig. 20 ist eine Skizzenansicht der sich bewegenden Tischvorrichtung, wobei gezeigt ist, wie der Tisch bewegt wird.

[0052] Fig. 21 ist eine Skizzenansicht einer fragmentarischen Skizzenansicht einer sich bewegenden Tischvorrichtung, die ein viertes Ausführungsbeispiel der Erfindung darstellt, und bei der eine Universalführungsvorrichtung entsprechend der vorliegenden Erfindung verwendet wird.

[0053] Fig. 22 ist ein Diagramm, das die Anordnung des Gleiters der in Fig. 21 gezeigten sich bewegenden Tischvorrichtung in einem krummlinigen Bereich zeigt.

[0054] In Fig. 1 ist eine Universalführungsvorrichtung entsprechend einem ersten Ausführungsbeispiel der vorliegenden Erfindung gezeigt. Eine Bahnschiene **1** ist in einem festen Abschnitt, so beispielsweise einem Sockel oder einem Fundament, angebracht. Gleiter **2** können sich entlang der Schiene **1** bewegen. Die Schiene **1** ist aus einem geradlinigen Führungsschienenabschnitt **1A**, einem krummlinigen Führungsschienenabschnitt **1B**, der als Bogen mit gegebenem Radius ausgebildet ist, und einem Übergangsschienenabschnitt **1C**, der die Schienenabschnitte **1A** und **1B** verbindet, zusammengesetzt. Die Gleiter **2** können sich entlang der Schienenabschnitte **1A**, **1B** und **1C** frei bewegen.

[0055] Fig. 2 ist eine perspektivische Ansicht des geradlinigen Führungsschienenabschnittes **1A**, wobei ein Gleiter **2** an dem Schienenabschnitt **1A** angeordnet ist. Fig. 3 ist eine Frontansicht in einem Querschnitt, der axial bezüglich des geradlinigen Führungsschienenabschnittes **1A** genommen ist. Der geradlinige Schienenabschnitt **1A** weist im Wesentlichen rechteckigen Querschnitt auf. Zwei seitliche Kugelrollflächen **10a** und zwei obere Kugelrollflächen **10b** erstrecken sich in Längsrichtung. Kugeln **3** rollen an den vier Rollflächen **10a**, **10b**. Die beiden seitlichen Kugelrollflächen **10a** sind an den gegenüberliegenden Seitenflächen des geradlinigen Führungsschienenabschnittes **1A** ausgebildet, wohingegen die beiden oberen Kugelrollflächen **10b** jeweils um die gegenüberliegenden Kanten der oberen Fläche des Führungsschienenabschnittes **1A** ausgebildet sind. Die seitlichen Kugelrollflächen **10a** sind unter einem Winkel von 30° in der Zeichnung aus der Horizontalen nach unten gekippt. Die oberen Kugelrollflächen **10b** weisen vertikal nach oben. Bolzenanbringlöcher **11** sind in dem geradlinigen Führungsschienenabschnitt **1A** ausgebildet und in Längsrichtung entlang des Schienenabschnittes **1A** gleichmäßig voneinander beabstandet. Ankerbolzen (nicht gezeigt) sind in die Bolzenanbringlöcher **11** eingebracht, sodass der Schienenabschnitt **1A** fest an dem festen Abschnitt angebracht ist.

[0056] Insbesondere Fig. 2 und Fig. 3 zeigen, dass jeder der vorstehend genannten Gleiter **2** einen beweglichen Block **4** und zwei Abdeckungen **5** umfasst, die jeweils am den vorderen und hinteren Endflächen des Blockes **4** angebracht sind. Der bewegliche Block **4** ist mit Gewindelöchern **42** versehen, in die die Ankerbolzen eingeschraubt sind. Der bewegliche Block **4** weist eine Anbringfläche **41** auf, an der ein bewegliche Körper, so beispielsweise ein Tisch, angebracht ist. Eine Endlosringstrecke für die Kugeln **3** ist im Inneren des Gleiters dadurch ausgebildet, dass die Abdeckungen **5** an dem beweglichen Block **4** angebracht sind. Abdichtungselemente **6**, die einen Gleitkontakt mit der Bahnschiene **1** herstellen, sind jeweils an den Abdeckungen **5** angebracht, wodurch verhindert wird, dass an der Schiene **1** anhaftender Staub während der Bewegung des Gleiters in den Gleiter **2** eintritt.

[0057] Wie insbesondere in Fig. 3 gezeigt ist, weist der vorgenannte bewegliche Block **4** einen horizontalen Abschnitt **4a** und ein Paar von Berandungsabschnitten **4b** auf, die von dem horizontalen Abschnitt **4a** ausgehen. Der Block **4** weist einen sattelartigen Querschnitt auf. Der Anbringabschnitt **41** ist in dem horizontalen Abschnitt **4a** ausgebildet. Zwei geradlinige Lastrollflächen **43a** sind an den Innenflächen der Berandungsabschnitte **4b** des beweglichen Blockes **4** ausgebildet und gegenüber den seitlichen Kugelrollflächen **10a** des geradlinigen Führungsschienenabschnittes **1A** angeordnet. Zwei geradlinige Lastrollflächen **43b** sind an der unteren Fläche des horizontalen Abschnittes **4a** ausgebildet und gegenüber den oberen Kugelrollflächen **10b** des geradlinigen Führungsschienenabschnittes **1A** angeordnet. Kugelrücklauflöcher **44a**, die den Lastrollflächen **43a** zugeordnet sind, sind jeweils in den Berandungsabschnitten **4b** ausgebildet. Kugelrücklauflöcher **44b**, die den Lastrollflächen **43b** zugeordnet sind, sind in dem horizontalen Abschnitt **4a** ausgebildet. U-förmige Richtungsänderungsstrecken **51** (Fig. 4) sind jeweils in den Abdeckungen **5** ausgebildet, um die Lastrollflächen **43a** und **43b** jeweils mit den Kugelrücklauflöchern **44a** und **44b** zu verbinden, wodurch eine Endlosringstrecke für die Kugeln gebildet ist.

[0058] Einige der Kugeln **3** tragen eine Last zwischen der Kugelrollfläche **10a** des geradlinigen Führungsschienenabschnittes **1A** und der Lastrollfläche **43b** des beweglichen Blockes **4**. Die anderen Kugeln **3** tragen eine Last zwischen der oberen Kugelrollfläche **10b** des geradlinigen Führungsschienenabschnittes **1A** und der Lastrollfläche **43b** des beweglichen Blockes **4**. Mit der Bewegung jedes Gleiters **2** führen die Kugeln **3** eine Rollbewegung über die Lastrollflächen **43a** und **43b** aus. Anschließend werden die Kugeln **3** entlastet und treten in die Richtungsänderungsstrecke **51** in der einen Abdeckung **5** ein. Die Kugeln rollen sodann durch die Kugelrücklauflöcher **44a** und **44b** in dem beweglichen Block **4** in der zur Richtung der Rollbewegung an den Lastrollflächen **43a** und **43b** entgegengesetzten Richtung, wobei sie in einem unbelasteten Zustand verbleiben. Nach der Rollbewegung durch die Kugelrücklauflöcher **44a** und **44b** treten die Kugeln **3** erneut in den Spalt zwischen der geradlinigen Führungsschiene **1A** und dem beweglichen Block **4** durch die Richtungsänderungsstrecke **51** in der anderen Abdeckung **5** ein und rollen anschließend an den Lastrollflächen **43a** und **43b**, wobei sie eine Last tragen.

[0059] Kugelhalteplatten **45** und **46** sind jeweils an den unteren Enden der Berandungsabschnitte **4b** und dem horizontalen Abschnitt **4a** des beweglichen Blockes **4** angeordnet. Die Kugelhalteplatten **45** und **46** werden aus einer Metallplatte ausgestanzt oder aus einem synthetischen harten Harz mittels Spritzgießen oder mittels eines anderen Verfahrens hergestellt. Die Kugelhalteplatten **45** und **46** verhindern, dass die an den Kugelrollflächen **10a** und **10b** rollenden Kugeln **3** den Gleiter **2** verlassen, wenn der Gleiter **2** von der Bahnschiene **1** entfernt wird.

[0060] Fig. 4 zeigt, wie die Kugeln **3** an den seitlichen Rollflächen **10a** rollen, die an den Seitenflächen des geradlinigen Führungsschienenabschnittes **1A** ausgebildet sind, wobei die Kugeln entlang der Strecke umlaufen, wenn sich jeder Gleiter **2** entlang des geradlinigen Führungsschienenabschnites **1A** bewegt. Die Kugeln **3**, die an den an der oberen Fläche des geradlinigen Führungsschienenabschnittes **1A** ausgebildeten oberen Kugelrollflächen **10b** rollen, führen eine ähnliche Roll- und Umlaufbewegung aus.

[0061] Wie vorstehend erwähnt wurde, sind die den Lastrollflächen **43a** und **43b** entsprechenden Richtungsänderungsstrecken **41** in den beiden Abdeckungen **5** ausgebildet, die jeweils an gegenüberliegenden Endflächen des beweglichen Blockes **4** ausgebildet sind. Durch Anbringen der Abdeckungen **5** an dem beweglichen Block **4** bildet der Gleiter **2**, wie gezeigt, eine Endlosringstrecke für die Kugeln **3**. Die Rollflächen **10a** und **10b** erstrecken sich linear und in Längsrichtung entlang des geradlinigen Führungsschienenabschnittes **1A**. Darüber hinaus sind die Lastrollflächen **43a** und **43b** des Gleiters **2** gegenüber den Rollflächen **10a** und **10b** jeweils linear ausgebildet. Aus diesem Grund sind sämtliche gleichzeitig an den Lastrollflächen **43a** und **43b** rollenden Kugeln **3** in Kontakt mit den Rollflächen **10a** beziehungsweise **10b** des geradlinigen Führungsschienenabschnittes **1A**, was in Fig. 4 gezeigt ist. Dies bedeutet, dass, während sich der Gleiter **2** entlang des geradlinigen Führungsschienenabschnittes **1A** bewegt, keine der Kugeln **3** unbelastet ist, ohne dass die Last zwischen der Rollfläche **10a** oder **10b** an der Seite der Führungsschiene **1** und der Lastrollfläche **43a** oder **43b** an der Seite des Gleiters **4** getragen wäre. Liegt eine große Last an dem Gleiter **2** an, so wird die Last verlässlich getragen, wobei sich der Gleiter **2** gleichmäßig bewegen kann.

[0062] Fig. 5 ist eine im Querschnitt genommene Frontansicht des krummlinigen Führungsschienenabschnittes **1B**, wobei ein Gleiter **2** hieran angebracht ist. Der krummlinige Führungsschienenabschnitt **1B** weist eine Querschnittsform auf, die ähnlich derjenigen des vorstehend beschriebenen geradlinigen Führungsschienenabschnittes ist. Der krummlinige Führungsschienenabschnitt **1B** ist als Bogen ausgebildet, der eine gegebene Krümmung R in Längsrichtung aufweist. Seitliche Rollflächen **12a**, die jeweils an die seitlichen Rollflächen **10a** anschließen, die wiederum an den gegenüberliegenden Seitenflächen des geradlinigen Führungsschienenabschnittes **1A** angeordnet sind, sind an den gegenüberliegenden Seitenflächen des krummlinigen Führungsschienenbereiches **1B** angeordnet. Obere Rollflächen **12b**, die jeweils an die oberen Rollflächen **10b** anschließen, die wiederum an der oberen Fläche des geradlinigen Führungsschienenabschnittes **1A** ausgebildet sind, sind an der oberen Fläche des krummlinigen Führungsschienenabschnittes **1B** ausgebildet.

[0063] Da der krummlinige Führungsschienenabschnitt **1B** derart ausgebildet ist, dass er eine gegebene Krümmung aufweist, ergibt sich für den Fall, dass die Breite L_2 des krummlinigen Führungsschienenabschnittes **1B** gleich der Breite L_1 des geradlinigen Führungsschienenabschnittes **1A** gewählt ist, dass die innere Seitenfläche des krummlinigen Führungsschienenabschnittes **1B** durch die Berandungsabschnitte **4b** oder im Zusammenhang mit den Abdeckungen **5** begrenzt ist. Aus diesem Grunde ist die Breite L_2 des krummlinigen Führungsschienenabschnittes **1B** kleiner als die Breite L_1 des geradlinigen Führungsschienenabschnittes **1A** gewählt. Zum Vergleich ist der Querschnitt des geradlinigen Führungsschienenabschnittes **1A** in der Zeichnung durch eine Punkt-Strich-Linie angedeutet. Wird die Breite L_2 des krummlinigen Führungsschienenabschnittes **1B** kleiner als die Breite L_1 des geradlinigen Führungsschienenabschnittes **1A** gewählt, so muss lediglich die innere Seitenfläche des krummlinigen Führungsschienenabschnittes **1B**, wie in Fig. 5 gezeigt, geschliffen werden. Alternativ können, wie in Fig. 16 gezeigt, sowohl die innere Seitenfläche wie auch die äußere Seitenfläche geschliffen sein.

[0064] Fig. 6 zeigt, wie die Kugeln **3** rollen und entlang der Ringstrecke umlaufen, wenn sich der Gleiter **2** entlang des krummlinigen Führungsschienenabschnittes **1B** bewegt. Es ist gezeigt, wie die Kugeln **3** an den Rollflächen **12a** rollen, die an den gegenüberliegenden Seitenflächen des krummlinigen Führungsschienenabschnittes **1B** ausgebildet sind. Die Rollflächen **12a** sind als Bogen in Längsrichtung der krummlinigen Führungsschienenabschnitte **1B** ausgebildet. Demgegenüber sind die Lastrollflächen **43a** des Gleiters **2** gegenüber den Rollflächen **12a** linear ausgebildet. Daher liegen, wie in Fig. 6 gezeigt, innerhalb des krummlinigen Führungsschienenabschnittes **1B** nur diejenigen Kugeln **3** an den Rollflächen **12a** an, die in der Nähe der beiden Enden der Lastrollflächen **43a** befindlich sind. Außerhalb des krummlinigen Führungsschienenabschnittes **1B** liegen lediglich diejenigen Kugeln an den Rollflächen **12a** an, die in den mittleren Bereichen der Lastrollflächen **43a** befindlich sind. Dies bedeutet, dass für den Fall, dass sich der Gleiter **2** entlang des krummlinigen Führungsschienenabschnittes **1B** bewegt, lediglich derjenige Teil der Kugeln **3**, der an den Lastrollflächen **43a** des Gleiters **2** rollt, eine Last trägt, wohingegen die übrigen Kugeln **3** unbelastet sind und die Last nicht tragen. Es ist einsichtig, dass sämtliche Kugeln **3**, die an den Lastrollflächen **43a** rollen, an den Rollflächen **12a** des krummlinigen Führungsschienenabschnittes **1B** in Abhängigkeit von der Krümmung des krummlinigen Führungsschienenabschnittes **1B** anliegen. Auch in diesem Fall tragen einige Kugeln **3** wenig zum Tragen der Last bei und sind unbelastet. Auch für den Fall, dass einige Kugeln **3** unbelastet sind und nicht auf diese Weise an den Rollflächen **12a** des krummlinigen Führungsschienenabschnittes **1B** anliegen, lösen die Kugeln **3** den Eingriff zwischen den Lastrollflächen **43a** und den Rollflächen **12** nicht, da die Kugelhalteplatte **46** an dem Gleiter **2** angebracht ist.

[0065] Fig. 7 zeigt, wie die Kugeln **3** an den Lastrollflächen **43b** rollen, die an dem horizontalen Abschnitt **4a** des Gleiters **2** ausgebildet sind. Dies bedeutet, dass Fig. 7 eine Perspektive des Gleiters **2** von oberhalb des krummlinigen Führungsschienenabschnittes **1B** darstellt. Da die Lastrollfläche **43b** des Gleiters **2** geradlinig ist, während die gegenüberliegende Rollfläche **12b** des krummlinigen Führungsschienenabschnittes **1B** als Bogen ausgebildet ist, liegen für den Fall, dass die Breite der Rollflächen **12b** gleich der Breite der seitlichen Rollfläche **12a** an dem krummlinigen Führungsschienenabschnitt und der Breite der Lastrollflächen **43b** ist, einige der Kugeln **3**, die an der Lastrollfläche **43b** an der Unterseite des Gleiters **2** rollen, an der inneren Fläche der Rollfläche **12b** an. Die übrigen verlassen die Rollfläche **12b** und liegen an der oberen Fläche des krummlinigen Führungsschienenabschnittes **1B** an. Infolgedessen können die Kugeln **3** gleichmäßig entlang der Endlosringstrecke in dem Gleiter **2** umlaufen.

[0066] Aus diesem Grunde ist die Rollfläche **12b**, die an der oberen Fläche des krummlinigen Führungsschienenabschnittes **1B** ausgebildet ist, derart ausgebildet, dass sie eine größere Nutbreite d als die Lastrollflächen **43b** aufweist, sodass sämtliche Kugeln **3**, die an den Lastrollflächen **43b** rollen, gleichzeitig an den Rollflächen **12b**, wie in Fig. 7 gezeigt, anliegen. Fig. 8 ist eine vergrößerte Ansicht, die zeigt, wie die Kugeln **3** die Rollflächen zwischen der Lastrollfläche **43b** an der Unterseite des Gleiters **2** und der Rollfläche **12b** an der Oberseite des krummlinigen Führungsschienenabschnittes **1B** berühren. Die durchgezogene Linie zeigt, wie die Kugeln die Rollflächen im Querschnitt α-α von Fig. 7 berühren. Die Punkt-Strich-Linie zeigt, wie die Kugeln die Rollflächen im Querschnitt β-β berühren. Die Rollflächen **12b** sind breiter als die Lastrollflächen **43a** gewählt. Darüber hinaus sind die Rollflächen **12b** als Bogen mit einer Krümmung in horizontaler Richtung in der Ebene von Fig. 8 ausgebildet. Aus diesem Grund bewegen sich, wenn die Kugeln **3** an den geradlinigen Lastrollflächen **43b** rollen, die Positionen, an der die Kugeln die Rollflächen **12b** berühren, nach rechts und links. Die Kugeln rollen an den Lastrollflächen **43b**, während die Last zwischen dem Gleiter und dem krummlinigen Führungsschienenabschnitt durchweg gehalten ist.

[0067] Bei der Universalführungsvorrichtung dieses Ausführungsbeispieles ist daher der krummlinige Führungsschienenabschnitt **1B** schmäler als der geradlinige Führungsschienenabschnitt **1A** gewählt. Wann immer eine Rollfläche für die Kugeln **3** für die obere Fläche der Bahnschiene **1** benötigt wird, wird lediglich die Rollfläche **12b** an der oberen Fläche des krummlinigen Führungsschienenabschnittes **1B** breiter als die Lastrollfläche **43b** an der Unterseite des Gleiters **2** gewählt. Daher kann sich der Gleiter **2** frei zwischen dem geradlinigen Führungsschienenabschnitt **1A** und dem krummlinigen Führungsschienenabschnitt **1B** bewegen, obwohl der Gleiter **2** derselbe wie bei der linearen Struktur einer Führungsvorrichtung aus dem Stand der Technik ist.

[0068] Bewegt sich der Gleiter **2** entlang des krummlinigen Führungsschienenabschnittes **1B**, so ist die Anzahl derjenigen Kugeln **3**, die an den seitlichen Rollflächen **12a** des krummlinigen Führungsschienenabschnittes **1B** anliegen, geringer als die Anzahl derjenigen Kugeln **3**, die an den seitlichen Rollflächen **10a** des geradlinigen Führungsabschnittes **1A** anliegen. Es kann daher nicht abgestritten werden, dass die Fähigkeit des Gleiters **2**, eine Last in dem krummlinigen Bereich der Bahnschiene **1** zu tragen, abnimmt. Gleichwohl ist die Fähigkeit des geradlinigen Bereiches, eine Last zu tragen, im Vergleich zum krummlinigen Bereich nicht geschmälert. Wirkt in dem krummlinigen Bereich auf den Gleiter **2** eine große Last, so kann diese Last ausreichend getragen werden.

[0069] Bei der vorstehend beschriebenen Universalführungsvorrichtung entsprechend der vorliegenden Erfindung sind die Lastrollflächen **43a** und **43b** des Gleiters **2** linear ausgebildet und weisen keine Vorzugsrichtung auf. Daher kann sich der Gleiter **2** entlang des krummlinigen Führungsschienenabschnittes **1B** problemlos bewegen, und zwar unabhängig davon, ob der krummlinige Führungsschienenbereich **1B** nach rechts oder nach links gebogen ist. Aus diesem Grund kann sich, wie in Fig. 9 gezeigt, der Gleiter **2** auch entlang einer S-förmigen Bahnschiene **1** bewegen, die sich aus zwei krummlinigen Führungsschienenabschnitten **1B** mit verschiedenen Krümmungsrichtungen zusammensetzt: Darüber hinaus ist nicht von Nöten, dass sämtliche aufeinanderfolgenden krummlinigen Führungsschienenabschnitte **1B** in einer kontinuierlichen Bahnschiene **1** als Bögen mit gleichem Radius ausgebildet sind. Der Gleiter kann auch dann frei bewegt werden, wenn krummlinige Schienenabschnitte verschiedener Radien kombiniert sind.

[0070] Wie in Fig. 10 gezeigt ist, wird der krummlinige Führungsschienenabschnitt **1B**, der mit einer gleichmäßigen Krümmung ausgebildet ist, in zwei Schienenstücke **16** und **17** zerschnitten. Anschließend wird ein Schienenstück **17** um 180° gedreht und mit dem anderen Schienenstück **16** derart kombiniert, dass eine S-förmige Bahnschiene **1** gebildet ist. Auch in diesem Fall kann der Gleiter **2** frei entlang der Bahnschiene **1** bewegt werden.

[0071] In Fig. 11 ist das Übergangsschienenstück **1C** gezeigt, das den geradlinigen Führungsschienenabschnitt **1A** und den krummlinigen Führungsschienenabschnitt **1B** verbindet. Es ist möglich, die Bahnschiene **1** dadurch aufzubauen, dass der geradlinige Führungsschienenabschnitt **1A** und der krummlinige Führungsschienenabschnitt **1B** verbunden werden, ohne dass der Übergangsschienenabschnitt **1C** verwendet würde. Wie vorstehend erwähnt, ist der krummlinige Führungsschienenabschnitt **1B** schmäler als der geradlinige Führungsschienenabschnitt **1A** ausgebildet. Darüber hinaus ist die Rollfläche **12b** des krummlinigen Führungsschienenabschnittes **1B** breiter als die obere Rollfläche **10b** des geradlinigen Führungsschienenabschnittes **1A** gewählt. Aus diesem Grund wird für den Fall, dass der geradlinige Führungsschienenabschnitt **1A** und der krummlinige Führungsschienenabschnitt **1B** direkt miteinander verbunden sind, die gleichmäßige Bewegung des Gleiters **2** unter Umständen leicht behindert. Aus diesem Grund ist bei dem dargestellten Ausführungsbeispiel der Übergangsschienenabschnitt **1C** zwischen den geradlinigen Führungsschienenabschnitt **1A** und den krummlinigen Führungsschienenabschnitt **1B**

geschaltet, um den Gleiter **2** gleichmäßig von dem geradlinigen Führungsschienenabschnitt **1A** zu dem krummlinigen Führungsschienenabschnitt **1B** und umgekehrt zu fördern.

[0072] Der Übergangsschienenabschnitt **1C** weist eine Querschnittsform auf, die ähnlich derjenigen des geradlinigen Führungsschienenabschnittes **1A** ist, und erstreckt sich linear. Der Übergangsschienenabschnitt **1C** weist Kugelrollflächen auf, die an die Kugelflächen **10a** und **10b** des geradlinigen Führungsschienenabschnittes **1A** und an die Rollflächen **12a** und **12b** des krummlinigen Führungsschienenabschnittes **1B** anschließen. Da der krummlinige Führungsschienenabschnitt **1B** schmäler als der geradlinige Führungsschienenabschnitt **1A** ausgebildet ist, ist die Seitenfläche **14** des Übergangsschienenabschnittes **1C**, die an die innere Seitenfläche des krummlinigen Führungsschienenabschnittes **1B** anschließt, schräg an der Seite an dem Ende des krummlinigen Führungsschienenabschnittes **1B**, wie durch die Punkt-Strich-Linie in Fig. 13 angedeutet, abgeschnitten. Die Breite nimmt von dem geradlinigen Führungsschienenabschnitt **1A** zu dem krummlinigen Führungsschienenabschnitt **1B** hin allmählich ab. Daher schließt die seitliche Rollfläche **10a**, die an der Seite des geradlinigen Führungsschienenabschnittes **1A** ausgebildet ist, an die Rollfläche **12b** an, die an der Seitenfläche des krummlinigen Führungsschienenabschnittes **1B** angeordnet ist, ohne dass stufenartige Änderungen auftreten. Die Kugeln können daher gleichmäßig zwischen den Rollflächen **10a** und **12a** rollen.

[0073] Wie in Fig. 11 gezeigt ist, ist eine Kugelrollfläche **13a**, die an die Rollfläche **10b** des geradlinigen Führungsschienenabschnittes **1A** und an die Rollfläche **12b** des krummlinigen Führungsschienenabschnittes **1B** anschließt, an der oberen Fläche des Übergangsschienenabschnittes **1C** ausgebildet. Wie in Fig. 12 und Fig. 13 gezeigt ist, nimmt die Breite der Kugelrollfläche **13B** an der Seite am Ende des krummlinigen Führungsschienenabschnittes **1B** allmählich zu. Dies erzeugt eine Verbindung zwischen den Rollflächen **10a** und **12b** mit unterschiedlichen Breiten, ohne dass stufenartige Änderungen vorhanden wären. Aus diesem Grund rollen Kugeln, die an der Rollfläche **12b** des krummlinigen Führungsschienenabschnittes **1B** gerollt sind, auf die obere Rollfläche **10b** des schmäler als die Rollfläche **12b** seienden geradlinigen Führungsschienenabschnittes, ohne dass sie hiervon in Eingriff genommen würden. Auf diese Weise kann sich der Gleiter gleichmäßig von dem krummlinigen Bereich in den geradlinigen Bereich der Bahnschiene bewegen.

[0074] In Fig. 14 ist eine Universalführungsvorrichtung entsprechend einem zweiten Ausführungsbeispiel der vorliegenden Erfindung gezeigt. Eine Bahnschiene **7** und ein Gleiter **8** weisen einen ähnlichen Grundaufbau wie die jeweiligen Entsprechungen beim vorstehend beschriebenen ersten Ausführungsbeispiel auf. Im Unterschied hierzu weist die Schiene **7** zwei Kugelrollflächen **71a** und zwei Kugelrollflächen **71b** an gegenüberliegenden Seiten, ein Paar über dem anderen, auf. Die oberen Rollflächen **71a** sind unter einem Winkel von 45° nach oben verkippt. Die unteren Rollflächen **71b** sind unter einem Winkel von 45° nach unten verkippt. Der Gleiter **8** weist Lastrollflächen **81a** und **81b** auf, die unter Winkeln verkippt sind, die den Kugelrollflächen **71a** beziehungsweise **71b** entsprechen.

[0075] Fig. 14 zeigt, wie der Gleiter **8** an dem geradlinigen Bereich der Bahnschiene **7**, das heißt an dem geradlinigen Führungsschienenabschnitt **7A**, angeordnet ist. Ein krummliniger Führungsschienenabschnitt **7B**, der an den geradlinigen Führungsschienenabschnitt **7A** anschließt, ist schmäler als der geradlinige Führungsschienenabschnitt **7A** gewählt, und zwar auf gleiche Weise wie beim ersten Ausführungsbeispiel. Fig. 15 ist eine im Querschnitt genommene Frontansicht des krummlinigen Führungsschienenabschnittes **7B**, in der der Umriss des geradlinigen Führungsschienenabschnittes **7A** zudem durch eine Punkt-Strich-Linie angedeutet ist.

[0076] Bei der auf diese Weise aufgebauten Universalführungsvorrichtung entsprechend dem zweiten Ausführungsbeispiel der Erfindung ist der krummlinige Führungsschienenabschnitt **7B** schmäler als der geradlinige Führungsschienenabschnitt **7A** gewählt, und zwar auf dieselbe Weise, wie dies beim ersten Ausführungsbeispiel der Fall ist. Infolgedessen kann sich der Gleiter **8** frei zwischen dem geradlinigen Führungsschienenabschnitt **7A** und dem krummlinigen Führungsschienenabschnitt **7B** bewegen.

[0077] Bei den vorstehend angegebenen Ausführungsbeispielen findet die vorliegende Erfindung bei Universalführungsvorrichtungen Verwendung. Wird eine ringförmige Bahnschiene dadurch zusammengestellt, dass mehrere krummlinige Führungsschienenabschnitte mit vorstehend beschriebener Struktur kombiniert werden, so kann sich der Gleiter entlang dieser Schiene bewegen. Eine krummlinige Führungsvorrichtung kann einfach konstruiert werden.

[0078] Bei den dargestellten Ausführungsbeispielen sind die Lastrollflächen **43a** und **43b**, die an dem Gleiter **2** ausgebildet sind, linear ausgebildet. Aus diesem Grunde kann eine Universalführungsvorrichtung dadurch hergestellt werden, dass Gleiter bestehender linearer Führungsvorrichtungen direkt eingesetzt werden. Entsprechend wird bei den vorstehend beschriebenen Ausführungsbeispielen der krummlinige Führungsschienenabschnitt **1B** schmäler als der geradlinige Führungsschienenabschnitt **1A** gewählt, um zu ermöglichen, dass sich der Gleiter der geradlinigen Führungsvorrichtung leicht entlang des krummlinigen Führungsschienenabschnittes **1B** bewegt. Aufgrund des Krümmungsradius des krummlinigen Führungsschienenabschnittes **1B** kann es jedoch unmöglich sein, die Struktur in ausreichendem Maße allein durch eine Verringerung der Breite des krummlinigen Führungsschienenabschnittes **1B** anzupassen. Der krummlinige Führungsschienenabschnitt **1B** kann durch die Berandungsabschnitte **4b** der Gleiter **2** oder im Zusammenhang mit den Abdeckungen **5** in seiner Bewegung beeinträchtigt werden. Entsprechend wird in diesem Fall die Länge des Gleiters **2**, genommen in Längsrichtung bezüglich der Bahnschiene **1**, verringert, wodurch eine Wechselwirkung zwischen dem krummlinigen Führungsschienenabschnitt **1B** und dem Gleiter **2** verhindert wird.

[0079] In Fig. 17 und Fig. 18 ist eine sich bewegende Tischvorrichtung gezeigt, bei der eine Universalführungsvorrichtung entsprechend einem Ausführungsbeispiel der vorliegenden Erfindung zum Einsatz kommt, wobei die sich bewegende Tischvorrichtung ein drittes Ausführungsbeispiel der Erfindung darstellt. Bahnschienen **1** und **1'** sind an einem festen Abschnitt, so beispielsweise an einem Sockel oder einem Fundament, angebracht. Gleiter **2** können sich entlang der Schienen **1** und **1'** bewegen. Ein Tisch **92** ist an den Gleitern angeordnet.

[0080] Die Bahnschienen **1** und **1'** setzen sich aus der ersten Schiene **1** und der zweite Schiene **1'** zusammen, die sich parallel erstrecken und gleichmäßig voneinander beabstandet sind. Die Schiene **1** umfasst einen geradlinigen Führungsschienenabschnitt **1A**, einen krummlinigen Führungsschienenabschnitt **1B**, der als Bogen mit gegebener Krümmung ausgebildet ist, sowie einen Übergangsschienenabschnitt **1C**, der den geradlinigen Führungsschienenabschnitt **1A** und den krummlinigen Führungsschienenabschnitt **1B** verbindet. Auf ähnliche Weise umfasst die Schiene **1'** einen geradlinigen Führungsschienenabschnitt **1'A**, einen krummlinigen Führungsschienenabschnitt **1'B**, der als Bogen mit gegebener Krümmung ausgebildet ist, sowie einen Übergangsschienenabschnitt **1'C**, der den geradlinigen Führungsschienenabschnitt **1'A** und den krummlinigen Führungsschienenabschnitt **1'B** verbindet. Die Krümmungsradien der krummlinigen Führungsschienenabschnitte **1B** und **1'B** seien R1 beziehungsweise R2. Die Mittelpunkte der Krümmungsradien fallen zusammen.

[0081] Mehrere Gleiter **2** (beispielsweise zwei) sind an jeder der Schienen **1** und **1'** angebracht. Insgesamt vier Gleiter tragen den Tisch. Die Gleiter **2** können sich frei an der ersten Schiene **1** (**1A**, **1B**, **1C**) und an der zweiten Schiene **1'** (**1'A**, **1'B**, **1'C**) bewegen. Ein Paar fester Platten **91** ist über den ersten und zweiten Reihen der Gleiter **2** – in Bewegungsrichtung an den Schienen **1** und **1'** betrachtet – angeordnet. Die festen Platten **91** weisen längliche Rechteckform auf und sind an den oberen Flächen der Gleiter **2** mittels Befestigungsmitteln, so beispielsweise mittels Schrauben, angebracht. Dies bedeutet, dass die festen Platten **91** – in Längsrichtung der Schienen **1** und **1'** betrachtet (das heißt in Richtung der Anordnung der Schienenabschnitte) – Gleiter **2** überspannen, die einander benachbart sind.

[0082] Der Tisch **92** ist derart angeordnet, dass er gegenüber den festen Platten drehbar ist. Eine Welle **93** ist an der unteren Fläche des Tisches **2** angeordnet. Drehlager **90** zum drehbaren Halten der Welle **93** sind an den oberen Flächen der festen Platten **91** angebracht. Die Drehlager **90** ermöglichen, dass der Tisch **92** gegenüber den festen Platten eine Drehung ausführt, während die Lager eine Last von dem Tisch **92** aufnehmen. Die Drehlager **90** sind in Gehäusen **94** angebracht, die wiederum in den festen Platten **91** angebracht sind. Jedes der Drehlager **90** weist eine äußere Laufbahn **90a**, die an dem Gehäuse angebracht ist, sowie eine innere Laufbahn **90b**, die an der Welle **93** angebracht ist, auf.

[0083] Fig. 19 zeigt eines der Drehlager **90**. Eine V-förmige Rollfläche ist sowohl an der äußeren Laufbahn **90a** wie auch an der inneren Laufbahn **90b** angeordnet. Eine Kugelrollstrecke von im Wesentlichen rechteckigem Querschnitt ist zwischen diesen Rollflächen ausgebildet. Mehrere Rollkörper **95** sind in der Rollkörperrollstrecke angeordnet und abwechselnd in Drehrichtung rechtwinklig zueinander verkippt. Die Rollkörper **95** rollen entlang der Rollkörperrollstrecke, wobei sie eine Last aufnehmen. Abstandshalter **96** sind zwischen benachbarten Rollkörpern **95** angeordnet, um die Rollkörper **95** in einem gegebenen Abstand zu halten.

[0084] Entlang der Rollkörperrollstrecke weisen zwei horizontal an denselben Abstandshalter **96** angrenzende Rollkörper **95** Achsen auf, die senkrecht zueinander sind. Die Rollkörper **95** werden in nach außen weisende Rollkörper **95a** und nach innen weisende Rollkörper **95b** unterteilt. Die Abstandshalter **96** halten die nach außen weisenden Rollkörper **95a** in einer derartigen Anordnung, dass deren Achsen C zur Drehmitte B hin weisen, die in der Drehmitte der äußeren Laufbahn **90a** und der inneren Laufbahn **90b** liegen.

[0085] Fig. 20 zeigt, wie die Bahnschienen **1** und **1'**, die jeweils aus den Schienenabschnitten **1A**, **1B** und **1C** sowie aus den Schienenabschnitten **1'A**, **1'B** und **1'C** bestehen, kombiniert werden, um eine S-Form zu erhalten. Die festen Platten **91** und der Tisch **92** bewegen sich entlang der S-förmigen Schiene. Während der Bewegung an den krummlinigen Schienenabschnitten **1B** und **1'B** sind die Gleiter **2** in tangentiale Richtung der krummlinigen Schienenabschnitte **1B** und **1'B** gerichtet. Daher drehen sich die an den

Gleitern **2** angebrachten festen Platten **91** um die Mitte O des Krümmungsradius. Als Ergebnis nimmt der Abstand zwischen den Gleitern **2**, die sich an der inneren Bahnschiene **1** bewegen, ab, wohingegen der Abstand zwischen den Gleitern **2**, die sich an der äußeren Bahnschiene **1'** bewegen, zunimmt. Da die festen Platten **91** drehbar an dem Tisch **92** angebracht sind, lassen die Platten derartige Abstandsschwankungen zwischen den Gleitern zu und ermöglichen so eine gleichmäßige Bewegung der Gleiter **2**.

[0086] Fig. 21 und Fig. 22 zeigen eine sich bewegende Tischvorrichtung, die bei einer Universalführungsvorrichtung entsprechend einem Ausführungsbeispiel der vorliegenden Erfindung zum Einsatz kommt, wobei die sich bewegende Tischvorrichtung ein viertes Ausführungsbeispiel der vorliegenden Erfindung darstellt. Beim vierten Ausführungsbeispiel sind die erste Bahnschiene **1** und die zweite Bahnschiene **1'** parallel zueinander angeordnet, wobei zwei Gleiter **2** an beiden Schienen **1** und **1'** angebracht sind. Diese vier Gleiter **2** tragen den Tisch **92** auf dieselbe Weise, wie dies beim dritten Ausführungsbeispiel der Fall ist. Gleichwohl unterscheidet sich die bewegliche Tischvorrichtung entsprechend dem vierten Ausführungsbeispiel von der beweglichen Tischvorrichtung entsprechend dem dritten Ausführungsbeispiel dadurch, dass die vier Gleiter **2** jeweils eigene Drehlager **90** aufweisen, und der Tisch **92** drehbar von dem Drehlager **90** gehalten wird. Die Drehlager **90** sind strukturell den Drehlagern beim dritten Ausführungsbeispiel ähnlich. An den vier Ecken des Tisches **92** angebrachte Wellen sind drehbar gehalten.

[0087] Bei der drehbaren Tischvorrichtung entsprechend diesem Ausführungsbeispiel tragen die Gleiter **2** die vier Ecken des Tisches **92**, weshalb der Tisch **92** stabiler als beim dritten Ausführungsbeispiel gehalten werden kann. Da die vier Gleiter **2** drehbar an dem Tisch gehalten werden, drehen sich die Gleiter **2**, die sich entlang der krummlinigen Führungsschienenabschnitte **1B** und **1'B** bewegen, beliebig und unabhängig voneinander und werden in tangentiale Richtung θ1, θ2, θ3 und θ4 der krummlinigen Führungsschienenabschnitte **1B**, **1'B**, wie in Fig. 22 gezeigt, ausgerichtet. Dies ermöglicht eine gleichmäßige Bewegung der Gleiter **2**.

[0088] Bewegt sich der Tisch **92** zwischen Bahnschienen **1** und **1'**, die verschiedene Krümmungsradien aufweisen, was beispielsweise dann der Fall ist, wenn eine Bewegung von den geradlinigen Bereichen **1A**, **1'A** der Schienen **1**, **1'** in die krummlinigen Bereiche **1B**, **1'B** erfolgt, so wird für den Fall, dass der Abstand zwischen den Gleitern **2** konstant gehalten wird, verhindert, dass die Gleiter **2** in ihrer Bewegung durch die Schienen **1** und **1'** beeinträchtigt werden, was eine gleichmäßige Bewegung des Tisches **2** verhindern würde. Gleichwohl sind Spalten zwischen den Gleitern **2** der Schienen **1**, **1'** dadurch vorgesehen, dass die Breite der Schienen **1** und **1'** schmäler als vorstehend beschrieben gewählt wird. Die Spalte beseitigen die Wechselwirkung zwischen den Gleitern **2** und den Schienen **1**, **1'**, sodass eine gleichmäßige Bewegung der Gleiter **2** sichergestellt ist.

Patentansprüche

1. Universalführungsvorrichtung, umfassend:
eine Bahnschiene (**1**; **7**) mit einem geradlinigen Bereich (**1A**; **7A**) und wenigstens einem krummlinigen Bereich (**1B**; **7B**), der als Bogen mit einem gegebenen Krümmungsradius ausgebildet ist, sowie mit Kugelrollflächen (**10a**, **12a**; **71a**, **71b**), die an zwei gegenüberliegenden Seitenflächen in Längsrichtung der Bahnschiene ausgebildet sind;
einen Sattelform aufweisenden Gleiter (**2**; **8**), der bei Verwendung an der Bahnschiene (**1**; **7**) angeordnet ist und Lastrollflächen (**43a**; **81a**, **81b**), die gegenüber den Kugelrollflächen (**10a**, **12a**; **71a**, **71b**) der Bahnschiene (**1**; **7**) angeordnet sind, sowie Endlosringstrecken, die die Lastrollflächen enthalten, aufweist;
eine Anzahl von Kugeln (**3**), die in den in dem Gleiter (**2**; **8**) ausgebildeten Endlosringstrecken rollen und bei Verwendung eine Last zwischen den Kugelrollflächen (**10a**, **12a**; **71a**, **71b**) der Bahnschiene und den Lastrollflächen (**43a**; **81a**, **81b**) des Gleiters tragen;
dadurch gekennzeichnet,
dass sämtliche an dem Gleiter (**2**; **8**) ausgebildeten Lastrollflächen (**43a**; **81a**, **81b**) linear ausgebildet sind, und der krummlinige Bereich (**1B**; **7B**) der Bahnschiene (**1**; **7**) schmäler als der geradlinige Bereich (**1A**; **7A**) der Bahnschiene ausgebildet ist.

2. Universalführungsvorrichtung nach Anspruch 1, bei der die Kugeln (**3**) eine Last zwischen den bogenförmigen Kugelrollflächen (**12a**; **71a**, **71b**) in Längsrichtung der Bahnschiene (**1**; **7**) und den an dem Gleiter (**2**; **8**) ausgebildeten geradlinigen Lastrollflächen (**43a**; **81a**, **81b**) tragen, wenn sich der Gleiter durch den krummlinigen Bereich (**1B**; **7B**) der Bahnschiene bewegt.

3. Universalführungsvorrichtung nach Anspruch 1, bei der einige der an den Lastrollflächen (**43a**; **81a**, **81b**) an dem Gleiter (**2**; **8**) rollenden Kugeln (**3**) eine Last zwischen den Kugelrollflächen (**12a**; **71a**, **71b**) an der Bahnschiene (**1**; **7**) und den Lastrollflächen (**43a**; **81a**, **81b**) an dem Gleiter tragen, wenn sich der Gleiter durch den krummlinigen Bereich (**1B**; **7BB**) der Bahnschiene bewegt.

4. Universalführungsvorrichtung nach einem der vorhergehenden Ansprüche, bei der die Bahnschiene (**1**) eine nach oben weisende Kugelrollfläche (**10b**, **12b**) aufweist, die an einer oberen Fläche der Bahnschiene ausgebildet ist, bei der der Gleiter (**2**) eine nach unten weisende Lastrollfläche (**43b**) gegenüber

der nach oben weisenden Kugelrollfläche (**10b**, **12b**) der Bahnschiene aufweist, und bei der die Breite der nach oben weisenden Kugelrollfläche (**12b**) in dem krummlinigen Bereich (**1B**) der Bahnschiene (**1**) derart gewählt ist, dass sämtliche an der nach unten weisenden Lastrollfläche (**43b**) des Gleiters (**2**) rollenden Kugeln (**3**) die nach oben weisende Kugelrollfläche (**12b**) gleichzeitig berühren.

5. Universalführungsvorrichtung nach einem der vorhergehenden Ansprüche, bei der die Bahnschiene (**1**) zwei in verschiedene Richtungen gekrümmte krummlinige Bereiche (**16**, **17**) aufweist, wobei sich der eine der krummlinigen Bereiche nach rechts krümmt, und sich der andere der krummlinigen Bereiche nach links krümmt.

6. Universalführungsvorrichtung nach einem der vorhergehenden Ansprüche, bei der die Führungsschiene (**1**) dadurch gebildet wird, dass eine geradlinige Führungsschiene (**1A**) und eine krummlinige Führungsschiene (**1B**) kombiniert werden.

7. Universalführungsvorrichtung nach Anspruch 6, bei der die Bahnschiene (**1**) eine Übergangsschiene (**1C**) aufweist, die die geradlinige Führungsschiene (**1A**) und die krummlinige Führungsschiene (**1B**) verbindet, wobei die Übergangsschiene (**1C**) eine Breite aufweist, die vom Ende der geradlinigen Führungsschiene bis zum Ende der krummlinigen Führungsschiene kontinuierlich variiert.

8. Bewegliche Tischvorrichtung mit mehreren parallel zueinander angeordneten Universalführungsvorrichtungen und von den Universalführungsvorrichtungen geführter Tisch (**92**), wobei jede Universalführungsvorrichtung entsprechend Anspruch 1 festgelegt ist.

9. Bewegliche Tischvorrichtung nach Anspruch 8, bei der eine Mehrzahl von Bahnschienen (**1**, **1'**) parallel zueinander angeordnet ist, eine Mehrzahl von Gleitern (**2**) an jeder der Bahnschienen (**1**, **1'**) angeordnet ist, einander benachbarte und an verschiedenen Schienen (**1**, **1'**) befindliche Gleiter (**2**) durch feste Platten (**91**) verbunden sind, und der Tisch (**92**) derart angebracht ist, dass er gegenüber den festen Platten drehbar ist.

10. Bewegliche Tischvorrichtung nach Anspruch 8, bei der eine Mehrzahl von Bahnschienen (**1**, **1'**) parallel zueinander angeordnet ist, eine Mehrzahl von Gleitern (**2**) an jeder der Bahnschienen angeordnet ist, und der Tisch (**92**) derart angebracht ist, dass er gegenüber den Gleitern (**2**) drehbar ist.

Beschreibung

Technisches Gebiet

Die vorliegende Erfindung betrifft ein Verfahren zur Herstellung einer krummlinigen Führungsschiene zum Führen eines sich bewegenden Körpers entlang einer Kurve mit einer gegebenen Krümmung in einer krummlinigen Führungsvorrichtung zur Verwendung in einem Schwingungs-Isolierapparat, der bei einem Präzisionsgerät, einer Kunst- oder Handwerksvitrine oder ähnlichem angewendet wird, sowie eine krummlinige Führungsschiene, die gemäß dem erfindungsgemäßen Verfahren hergestellt wird.

Stand der Technik

In herkömmlicher Weise wird als eine Erdbeben-Maßnahme für Immobilien, wie z. B. ein Gebäude oder ein Haus, oder als eine Schwingungsmaßnahme, wenn ein Präzisionsgerät, eine Kunstvitrine oder ähnliches transportiert wird, eine Vibrations-Isoliervorrichtung verwendet, welche die Schwingungen der Erde oder eines Bodens absorbiert, um die Schaukelbewegung desselben zu mildern. Als eine Schwingungs-Isoliervorrichtung ist eine Vorrichtung bekannt, bei der eine krummlinige Führungsvorrichtung verwendet wird, die einen sich bewegenden Körper in einer krummlinigen Art und Weise entlang einer krummlinigen Führungsschiene führt (es sei beispielsweise auf die ungeprüfte japanische Patentveröffentlichung mit der Nr. Hei 10-122238 verwiesen).

Fig. 4 zeigt ein Beispiel einer Schwingungs-Isoliervorrichtung **100** mit einer krummlinigen Führungsvorrichtung. Die Schwingungs-Isoliervorrichtung **100** weist eine erste krummlinige Führungsvorrichtung **60**, die an einen Boden **50** befestigt ist, eine zweite krummlinige Führungsvorrichtung **70**, die an einen gelagerten Körper **51**, wie z. B. ein Präzisionsgerät, von dem Schwingungen durch die Vorrichtung **100** isoliert werden sollen, befestigt ist, und eine universelle Kupplung **80** auf, welche die beiden krummlinigen Führungsvorrichtungen **60** und **70** miteinander verbindet. Die erste und zweite krummlinige Führungsvorrichtung **60** und **70** sind derart angeordnet, dass sie unter einem rechten Winkel aufeinander treffen.

Ferner weisen die beiden krummlinigen Führungsvorrichtungen **60** und **70** jeweils krummlinige Führungsschienen **61** und **71**, die jeweils auf gekrümmte Art und Weise mit ihren jeweiligen gegebenen Krümmungen ausgebildet sind, und sich bewegende Körper **62** und **72** auf, die sich jeweils entlang ihrer zugeordneten krummlinigen Führungsschienen **61** und **71** bewegen. Die universelle Kupplung **80** verbindet die sich bewegenden Körper **62** und **72** der ersten und zweiten krummlinigen Führungsvorrichtung **60** und **70** miteinander. Die beiden krummlinigen Führungsvorrichtungen **60** und **70** werden vorangehend durch Biegen mit ihren jeweiligen Krümmungen ausgebildet, so dass sie nicht unmittelbar an den Boden zu befestigen sind, der eine Ebene bildet. Deshalb werden sie jeweils an den Boden **50** und an den gelagerten Körper **51** über ihre zugeordneten Befestigungsbasen **63** und **73** befestigt, die in gekrümmten Formen jeweils mit der gleichen Krümmung wie diejenige der krummlinigen Führungsvorrichtung **61** und **71** ausgebildet sind. In dieser Beschreibung bedeutet der Begriff "Biegen" ein "Biegen, bei dem plastische Verformung auftritt", d. h. er bedeutet, dass, nachdem die Schiene einmal durch Biegen ausgebildet ist, die Schiene nicht mehr unter normalen Umständen zu ihrer Ausgangsform zurückgebracht werden kann.

Fig. 5 ist eine schematische Ansicht der wie oben beschrieben aufgebauten Schwingungs-Isoliervorrichtung, wobei ein spezielles Verfahren zu deren Verwendung gezeigt ist. Wie **Fig.** 5 zeigt, bezeichnet die Referenznummer **50** einen Boden (eine Bodenoberfläche), und **51** steht für einen gelagerten Körper, wie z. B. eine Kunstvitrine. Vier Schwingungs-Isoliervorrichtungen **100** der oben beschriebenen Art sind jeweils an vier Stellen zwischen dem Boden **50** und dem gelagerten Körper **51** derart angeordnet, dass sie den gelagerten Körper **51** lagern. Dank dieser Anordnung bewegen sich, wenn der Boden infolge eines Erdbebens oder ähnlichem veranlasst wird, zu schwanken, die sich bewegenden Körper **62** und **72** der ersten und zweiten krummlinigen Führungsvorrichtung auf ihren jeweiligen krummlinigen Führungsschienen **61** und **71** derart, dass die Schaukelbewegung des Bodens **50** absorbiert wird, wodurch verhindert wird, dass sich die Schwingungen des Bodens **50** zu dem gelagerten Körper **51** übertragen.

Jedoch unterliegt die oben erwähnte, herkömmliche, krummlinige Führungsvorrichtung dem folgenden Problem. Es liegt darin, dass eine Führungsschiene, die durch Ziehen derart verformt wurde, dass sie einen bestimmten Querschnitt aufweist und immer noch in einer linearen Form verbleibt, einem Biegen unterworfen wird, wodurch eine krummlinige Führungsschiene erzeugt wird. Ferner ist es bei dem Biegevorgang erforderlich, die Führungsschiene mit einer bestimmten Krümmung zu biegen. Im Ergebnis erfordert es Zeit und Arbeit, um eine krummlinige Führungsschiene zu erzeugen.

Ferner wird, wenn eine Kugelrollfläche an einer krummlinigen Führungsschiene ausgebildet wird, weil die Kugelrollfläche nicht durch Schleifen der krummlinigen Führungsschiene ausgebildet werden kann, nachdem die krummlinige Führungsschiene gebogen wurde, eine entsprechende Schleifbearbeitung vor dem Biegevorgang durchgeführt. Zusätzlich ist es, da die Härte der Kugelrollfläche verbessert werden muss, erforderlich, eine Wärmebehandlung, wie z. B. ein Abbindungshärten der Oberfläche der Führungsschiene, durchzuführen, bevor der Schleifvorgang durchgeführt wird. Wenn jedoch Edelstahl als das Ausbildungsmaterial der Führungsschiene verwendet wird, um den Anforderungen beispielsweise im Hinblick auf eine Korrosionsvermeidung zu entsprechen, härtet die Härtebehandlung nicht nur die Oberfläche der Führungsschiene, sondern auch deren mittleren Abschnitt. Im Ergebnis entsteht, wenn die Führungsschiene über deren elastisch verformbare Grenze hinaus gebogen wird, das Problem, dass ein Riss in der krummlinigen Führungsschiene auftritt, die durch ein derartiges Biegen erzeugt wird.

Darstellung der Erfindung

Die vorliegende Erfindung wurde gemacht, um die Nachteile der obengenannten, herkömmlichen, krummlinigen Führungsschiene zu beheben, und es ist deshalb eine Aufgabe der Erfindung, ein Verfahren zur Herstellung einer krummlinigen Führungsschiene zu schaffen, das, wenn eine krummlinige Führungsschiene einer krummlinigen Führungsvorrichtung zum Führen eines sich bewegenden Körpers entlang einer gekrümmten Linie mit einer gegebenen Krümmung hergestellt wird, in der Lage ist, eine krummlinige Führungsschiene herzustellen, ohne dass unnötig Zeit und Arbeitskraft verwendet werden muss, und die somit bei geringen Kosten herzustellen ist.

Es ist eine weitere Aufgabe der Erfindung, eine krummlinige Führungsschiene zu schaffen, die mit geringem Aufwand an Zeit und Arbeit und bei geringen Kosten hergestellt werden kann.

Um die genannten Aufgaben zu lösen, wird gemäß einem

Aspekt der Erfindung ein Verfahren zur Herstellung einer krummlinigen Führungsschiene zum Führen eines sich bewegenden Körpers entlang einer gekrümmten Linie mit einer gegebenen Krümmung geschaffen, wobei das Verfahren folgende Schritte aufweist: Vorbereiten einer geraden Führungsschiene zum Führen eines sich bewegenden Körpers in geradliniger Art und Weise; Pressen einer unteren Fläche der geraden Führungsschiene zum Führen des sich bewegenden Körpers in einer geradlinigen Art und Weise gegen eine gekrümmte Schienenanbringfläche einer Schienenbefestigungsbasis, die mit einem gegebenen Krümmungsradius ausgebildet ist, um die geradlinige Führungsschiene elastisch auf krummlinige Art und Weise zu verformen; und Befestigen der geradlinigen Führungsschiene an die Schienenanbringfläche, während die geradlinige Führungsschiene elastisch verformt bleibt, so dass eine krummlinige Führungsschiene erzeugt wird.

Gemäß einem weiteren Aspekt der Erfindung wird eine krummlinige Führungsschiene zum Führen eines sich bewegenden Körpers entlang einer gekrümmten Linie mit einer gegebenen Krümmung geschaffen, wobei die krummlinige Führungsschiene folgendes aufweist: eine Schienenbefestigungsbasis mit einer gekrümmten Schienenanbringfläche, die mit einer gegebenen Krümmung ausgebildet ist; einen Schienenhauptkörper, der in eine geradlinige Form ausgebildet ist und in einer krummlinigen Art und Weise elastisch verformbar ist, wenn der Schienenhauptkörper gegen die Schienenanbringfläche der Schienenbefestigungsbasis gepresst wird; und eine Schienenbefestigungseinrichtung zum Befestigen des Schienenhauptkörpers an die Schienenanbringfläche.

Gemäß der Erfindung wird die untere Fläche der geraden Führungsschiene gegen die Schienenanbringfläche gepresst, die in eine gekrümmte Form ausgebildet ist, und die gerade Führungsschiene wird an die Schienenanbringfläche befestigt, während die gerade Führungsschiene innerhalb ihres elastisch verformbaren Bereichs verformt bleibt, wodurch eine krummlinige Führungsschiene zum Bewegen eines sich bewegenden Körpers entlang einer gekrümmten Linie mit einer gegebenen Krümmung ausgebildet wird. Infolge dieser Maßnahme wird nicht nur ein Biegevorgang, der Zeit und Arbeitskraft erfordert, weggelassen, sondern es kann ferner eine krummlinige Führungsschiene leicht hergestellt werden, und zwar indem eine gegenwärtig bereits bestehende lineare Führungsschiene verwendet wird, die auf dem Markt leicht erhältlich ist, was es ermöglicht, eine krummlinige Führungsschiene mit einer gegebenen Krümmung bei niedrigen Kosten herzustellen.

Ferner ist es gemäß der vorliegenden Erfindung erforderlich, eine Schienenbefestigungsbasis vorzusehen, gegen welche die untere Fläche der geraden Führungsschiene gepresst wird. In ähnlicher Weise ist es, auch bei der herkömmlichen krummlinigen Führungsschiene, wenn diese an einen Boden oder ähnliches befestigt wird, erforderlich, eine Schienenbefestigungsbasis mit einer gekrümmten Schienenanbringfläche zu verwenden. Jedoch wird gemäß der Erfindung die Anzahl der Einzelteile, die zur Befestigung der Schiene erforderlich ist, nicht über diejenige der herkömmlichen Führungsschiene hinaus vermehrt, jedoch kann eine krummlinige Führungsschiene bei Kosten hergestellt werden, die um ein Ausmaß gesenkt werden, das dem Weglassen des Biegevorgangs entspricht.

Ferner besteht bei der Erfindung, da die geradlinige Führungsschiene, die gegen die untere Fläche der Schienenanbringfläche gepresst wird, einfach innerhalb ihres elastisch verformbaren Bereichs verformt wird, auch wenn sie an die Schienenanbringfläche in dem verformten Zustand befestigt wird, nicht die Gefahr, dass ein Riss in der so befestigten geradlinigen Führungsschiene auftreten kann, und deshalb ist, auch wenn eine krummlinige Führungsschiene unter Verwendung eines derartigen Materials hergestellt wird, das durch einen Biegevorgang, bei dem plastische Verformung auftritt, brechen kann, das vorliegende Herstellungsverfahren sicher in der Lage, dieses Problem zu beheben, d. h. die Gefahr auszuschalten, dass ein Riss in der Führungsschiene auftritt.

Deshalb schafft die vorliegende Erfindung wirkungsvoll die Herstellung einer krummlinigen Führung durch Verwendung eines derartigen Materials, das schwierig zu biegen ist, nachdem es gehärtet wurde.

Ferner kann als die Schienenbefestigungseinrichtung zum Befestigen einer geradlinigen Führungsschiene, die gegen die gekrümmte Schienenanbringfläche gepresst und in einer gekrümmten Art und Weise elastisch verformt wurde, an die Schienenanbringfläche, während die geradlinige Führungsschiene elastisch verformt bleibt, eine beliebige Befestigungseinrichtung verwendet werden, vorausgesetzt, dass sie in der Lage ist, die geradlinige Führungsschiene an der Schienenanbringfläche gegen die elastische Kraft der geradlinigen Führungsschiene zu halten, welche die geradlinige Führungsschiene in ihre ursprüngliche Form zurückführen wird. Beispielsweise kann ein Befestigungsbolzen durch die geradlinige Führungsschiene eingeführt und mittels eines Gewindes mit der Schienenanbringfläche in Eingriff gebracht werden.

Ausführliche Beschreibung bevorzugter Ausführungsformen der Erfindung

Nachfolgend wird im einzelnen ein Verfahren zur Herstellung einer krummlinigen Führungsschiene gemäß der Erfindung unter Bezugnahme auf die beigefügten Zeichnungen beschrieben.

Fig. 1 zeigt eine krummlinige Führungsschiene, die durch ein Verfahren zur Herstellung einer krummlinigen Führungsschiene gemäß der Erfindung hergestellt wird. In **Fig.** 1 bezeichnet Referenznummer **1** einen Schienenhauptkörper, **2** bezeichnet eine Schienenbefestigungsbasis zum Anbringen des Schienenhauptkörpers **1** an eine feste Oberfläche B, wie z. B. die Oberfläche eines Bodens oder die Oberfläche eines gelagerten Körpers, und **3** bezeichnet einen Befestigungsbolzen, der als eine Schienenbefestigungseinrichtung dient, die durch den Schienenhauptkörper **1** eingeführt und mittels eines Gewindes mit der Schienenbefestigungsbasis **2** in Eingriff gebracht werden kann.

Eine Laufschiene (geradlinige Führungsschiene) **5**, wie in

Fig. 2 gezeigt ist, wird als der Schienenhauptkörper **1** verwendet. Wie in **Fig.** 2 gezeigt ist, weist die lineare Führungsvorrichtung die Laufschiene **5**, die in eine geradlinige Form ausgebildet ist und zwei Streifen von Krümmungen **50** aufweist, die jeweils entlang deren Längsrichtung ausgebildet sind, sowie einen sich bewegenden Körper **7** auf, der in eine sattelähnliche Form ausgebildet ist und rittlings auf der Laufschiene **5** sitzt und durch Kugeln **6** mit der Laufschiene **5** in Eingriff gebracht werden kann, so dass er frei entlang der Laufschiene **5** in der Längsrichtung gleitbar ist. Der sich bewegende Körper **7** weist nicht nur eine Last-Kugelrollfläche **70** auf, die mit der Kugelrollfläche **50** an der Laufschiene **5** zusammenwirkt, um die Kugel **6** zwischen diesen einzuschließen, sondern auch einen endlosen Zirkulationsdurchgang **71**, entlang dem die Kugeln **6**, die entlang der Last-Kugelrollfläche **70** gerollt sind, zirkuliert werden können. Mit dem obengenannten Aufbau einer geradlinigen Führungsvorrichtung wird, wenn sich der sich bewegende Körper **7** entlang der Laufschiene **5** bewegt, für die Kugeln **6** zugelassen, dass sie innerhalb des endlosen Zirkulationsdurchgangs **71** zirkulieren. Der sich bewegende Körper **7** weist ferner eine Anbringfläche **72** zum Anbringen eines beweglichen Elements daran auf, und in der Schwingungs-Isoliervorrichtung, die in **Fig.** 4 gezeigt ist, ist die universelle Kupplung **80** an die Anbringoberfläche **72** befestigt. In **Fig.** 2 bezeichnet Referenznummer **51** ein Bolzenanbringloch, durch welches der Befestigungsbolzen **3** zum Befestigen der Laufschiene **5** an die Schienenbefestigungsbasis **2** eingeführt werden kann.

Andererseits weist die Schienenbefestigungsbasis **2** nicht nur eine Schienenanbringfläche **20** auf, die in einer gekrümmten Form mit einer gegebenen Krümmung (beispielsweise 4–6 m) ausgebildet ist, sondern auch eine eben geformte untere Fläche **21**, die mit der oben erwähnten festen Oberfläche B in Berührung gebracht werden soll, während die Schienenbefestigungsbasis **2** auch als eine Klammer zur Anbringung des Schienenhauptkörpers **1** an die feste Oberfläche B dient. Ferner ist in der Schienenanbringfläche **20** eine Gewindeöffnung **22** geöffnet, in welche der Befestigungsbolzen **3** mittels eines Gewindes in Eingriff gebracht werden kann. Die Gewindeöffnung **22** ist entlang der unteren Fläche **21** der Schienenbefestigungsbasis **2** mit derselben Teilung wie diejenige der Bolzenanbringöffnung **51** der Laufschiene **5** ausgebildet.

Fig. 3 zeigt einen Vorgang zum Befestigen der geradlinig geformten Laufschiene **5** an die Schienenbefestigungsbasis **2** zur Erzeugung einer krummlinigen Führungsschiene.

Insbesondere wird die Laufschiene **5** der geradlinigen Führungsvorrichtung, wobei die Kugelrollfläche **50** und die Bolzenanbringöffnung **51** daran bereits ausgebildet sind, an der Schienenanbringfläche der Schienenbefestigungsbasis **2** angeordnet, eine Last F wird von oberhalb der Laufschiene **5** aufgebracht, um die untere Fläche **52** der Laufschiene **5** gegen die Schienenanbringfläche **20** zu pressen und somit die Laufschiene **5** elastisch zu verformen, und die Befestigungsbolzen **3** werden jeweils durch ihre zugeordneten Bolzenanbringöffnungen **51** eingeführt und nacheinander in ihre jeweils zugeordneten Gewindeöffnungen **22** der Schienenbefestigungsbasis **2** eingeschraubt. Im Ergebnis wird die Laufschiene **5** elastisch mit einer Krümmung verformt, die identisch zu der Krümmung **5** der Schienenanbringfläche **20** ist, und dann an die Schienenbefestigungsbasis **2** befestigt, während ihr elastisch verformter Zustand aufrechterhalten wird, um dadurch den oben beschriebenen Schienenhauptkörper **1** zu schaffen (vgl. **Fig.** 1). Da die Laufschiene einfach in einer krummlinigen Art und Weise innerhalb ihres elastisch verformbaren Bereichs verformt wird, wird, auch nachdem die Laufschiene **5** einmal an die Schienenanbringfläche **20** durch die Befestigungsbolzen **3** befestigt wurde, wenn die Befestigungsbolzen **3** entfernt werden, für die Laufschiene **5** zugelassen, dass sie in ihre ursprüngliche Form, zurück zu ihrer ursprünglichen geradlinigen Form zurückkehrt, und zwar mittels ihrer eigenen elastischen Kräfte.

Da die Gewindeöffnungen **22** derart ausgebildet sind, dass sie sich nicht entlang der Schienenanbringfläche **20** erstrecken, sondern entlang der unteren Fläche **21** der Schienenbefestigungsbasis **2**, und zwar mit der gleichen Teilung wie derjenigen der Bolzenbefestigungsöffnungen **51** in der Laufschiene **5**, könnte die Gefahr bestehen, dass die Bolzenanbringöffnungen **51** der Laufschiene **5** nicht mit den Gewindeöffnungen **22** der Schienenanbringfläche **20** in einem Zustand in Übereinstimmung gebracht werden können, wenn die Laufschiene **5** elastisch auf gekrümmte Art und Weise verformt wird. Jedoch wird im Normalzustand der Innendurchmesser einer jeden Bolzenanbringöffnung **51** größer ausgebildet als der Nenndurchmesser einer jeden Gewindeöffnung **22**, und in dem Fall, dass die Krümmung der Schienenanbringfläche **20** klein ist, besteht, auch wenn die Laufschiene **5** elastisch in gekrümmter Art und Weise verformt wird, keine Möglichkeit, dass die Bolzenanbringöffnung **51** und die Gewindeöffnung **22** in großem Umfang voneinander versetzt sind. Deshalb können die Befestigungsbolzen **3**, die jeweils durch die Bolzenanbringöffnungen **51** eingeführt wurden, mittels des Gewindes mit Leichtigkeit mit den Gewindeöffnungen **22** in Eingriff gebracht werden. Auch wenn die Krümmung der Schienenanbringfläche **20** groß ist, werden, wenn die Bolzenanbringöffnungen **51** der Laufschiene **5** jeweils in längliche Öffnungen ausgebildet werden, die Befestigungsbolzen **3**, die jeweils durch die Bolzenanbringöffnungen **51** eingeführt wurden, mittels des Gewindes mit den Gewindeöffnungen **22** mit Leichtigkeit in Eingriff gebracht, unabhängig von dem Ausmaß der elastischen Verformung der Laufschiene **5**.

Wie oben beschrieben, wird bei der krummlinigen Führungsschiene gemäß dieser Ausführungsform, da die Laufschiene **5** der geradlinigen Führungsvorrichtung, wenn sie gegen die Schienenanbringfläche **20** der Schienenbefestigungsbasis **2** gedrückt wird und an dieser befestigt wird, um eine krummlinige Führungsschiene mit einer Krümmung auszubilden, die zu der Krümmung der Schienenanbringfläche **20** identisch ist, die Notwendigkeit ausgeschaltet, eine Biegeoperation an der Laufschiene **5** durchzuführen, bei der eine plastische Verformung auftritt, was zu dem Ergebnis führt, dass, auch wenn das Material der Laufschiene **5** schwierig zu biegen ist, nicht die Gefahr besteht, dass ein Riss in der Laufschiene **5** auftreten kann. Ferner kann, weil die krummlinige Führungsschiene mit einer Krümmung, die identisch ist zu der Krümmung der Schienenanbringfläche **20** dadurch erhalten wird, dass einfach die Laufschiene **5** an die Schienenanbringfläche **20** befestigt wird, der Biegevorgang der Laufschiene **5** ohne die Notwendigkeit durchgeführt werden, deren Krümmung im einzelnen zu messen, so dass die krummlinige Führungsschiene sehr leicht hergestellt werden kann.

Wenn die Krümmung des Schienenhauptkörpers **1**, der an die Schienenbefestigungsbasis **2** befestigt ist, klein ist, kann die sich bewegende Basis **7** der geradlinigen Führungsvorrichtung so verwendet werden, wie sie vorliegt, da sich die bewegende Basis, die sich entlang der krummlinigen Führungsschiene bewegt, die so hergestellt wurde, ohne die Notwendigkeit zur Ausführung zusätzlicher Arbeitsvorgänge an der beweglichen Basis **7** der geradlinigen Führungsvorrichtung, hierfür eignet. Andererseits kann, wenn die Krümmung des Schienenhauptkörpers **1** groß ist, wenn die Last-Kugelrollfläche **70** der sich bewegenden Basis **7** ebenso wie die gemäß der Krümmung des Schienenhauptkörpers **1** mit einer Krümmung versehen wird, die Bewegung des sich bewegenden Körpers **7** an dem Schienenhauptkörper **1** sanft ausgeführt werden.

Wie oben beschrieben, wird als die Schienenbefestigungseinrichtung bei der vorangehend beschriebenen Ausführungsform der Befestigungsbolzen **3** verwendet, er kann jedoch durch bekannte Klebeverfahren, Schweißen, usw. ersetzt werden.

Wie vorangehend beschrieben wurde, kann durch Verwendung eines Verfahrens zur Herstellung einer krummlinigen Führungsschiene gemäß der Erfindung, bei dem eine geradlinige Führungsschiene an eine Schienenanbringfläche befestigt wird, die in einer gekrümmten Oberfläche mit einer gegebenen Krümmung derart ausgebildet ist, dass die geradlinige Führungsschiene elastisch verformt wird, eine krummlinige Führungsschiene mit einer gegebenen Krümmung ohne Biegen der geradlinigen Führungsschiene hergestellt werden. Infolge dieser Maßnahme wird nicht nur Zeit und Arbeitskraft für die Ausführung der ansonsten erforderlichen Biegebearbeitung weggelassen, sondern es kann ferner eine krummlinige Führungsschiene auf einfache Weise unabhängig von dem Material der Schiene hergestellt werden, so dass eine krummlinige Führungsschiene mit einer gegebenen Krümmung bei geringen Kosten hergestellt werden kann.

Patentansprüche

1. Verfahren zur Herstellung einer krummlinigen Führungsschiene zum Führen eines sich bewegenden Körpers entlang einer gekrümmten Linie mit einer gegebenen Krümmung, wobei das Verfahren folgende Schritte aufweist:
Pressen einer unteren Fläche einer geradlinigen Führungsschiene zum Führen des sich bewegenden Körpers in einer geradlinigen Art und Weise gegen eine gekrümmte Schienenanbringfläche einer Schienenbefestigungsbasis, die mit einem gegebenen Krümmungsradius ausgebildet ist, um die geradlinige Führungsschiene elastisch auf krummlinige Art und Weise zu verformen; und
Befestigen der geradlinigen Führungsschiene an die Schienenanbringfläche, während die geradlinige Führungsschiene elastisch verformt bleibt, so dass eine krummlinige Führungsschiene erzeugt wird.
2. Verfahren nach Anspruch 1, wobei die geradlinige Führungsschiene aus Edelstahlmaterial ausgeführt ist.
3. Krummlinige Führungsschiene (**5**) zum Führen eines sich bewegenden Körpers (**7**) entlang einer gekrümmten Linie mit einer gegebenen Krümmung, mit:
einer Schienenbefestigungsbasis (**2**) mit einer gekrümmten Schienenanbringfläche (**20**), die mit einer gegebenen Krümmung ausgebildet ist;
einem Schienenhauptkörper (**1**), der in eine geradlinige Form ausgebildet ist und in einer krummlinigen Art und Weise elastisch verformbar ist, wenn der Schienenhauptkörper (**1**) gegen die Schienenanbringfläche (**20**) der Schienenbefestigungsbasis (**2**) gepresst wird; und
einer Schienenbefestigungseinrichtung (**3**) zum Befestigen des Schienenhauptkörpers (**1**) an die Schienenanbringfläche (**20**).
4. Krummlinige Führungsschiene nach Anspruch 3, wobei der Schienenhauptkörper (**1**) aus Edelstahlmaterial ausgeführt ist.
5. Krummlinige Führungsschiene nach Anspruch 3, wobei die Schienenbefestigungseinrichtung (**3**) mehrere Befestigungsbolzen aufweist;
wobei die Schienenbefestigungsbasis (**2**) mehrere Bolzenanbringöffnungen (**51**) darin definiert, wobei die Schienenbefestigungsbasis mehrere Gewindeöffnungen (**22**) definiert, die den darin ausgebildeten Bolzenanbringöffnungen (**51**) zugeordnet sind, und die Gewindeöffnungen (**22**) entlang einer Bodenfläche der Schienenbefestigungsbasis mit der gleichen Teilung wie derjenigen der Bolzenanbringöffnungen (**51**) ausgebildet sind; und
wobei die Befestigungsbolzen (**3**) durch die zugeordneten Bolzenanbringöffnungen (**51**) treten und mittels eines Gewindes mit den zugeordneten Gewindeöffnungen (**22**) in Eingriff kommen.
6. Krummlinige Führungsschiene nach Anspruch 3, wobei die Bolzenanbringöffnungen (**51**) in ihrem Durchmesser größer sind als die Gewindeöffnungen (**22**).
7. Krummlinige Führungsschiene nach Anspruch 3, wobei die Bolzenanbringöffnungen aus länglichen Öffnungen bestehen.

DE 198 30 578 A 1

Beschreibung

HINTERGRUND DER ERFINDUNG

Gebiet der Erfindung

Die vorliegende Erfindung bezieht sich auf einen Linearführungsapparat für schwere Lasten, in welchem in Kombination Rollen und Kugeln als Rollelemente verwendet werden.

Beschreibung des verwandten Standes der Technik

In bezug auf einen konventionellen Linearführungsapparat für schwere Lasten, ist ein Linearführungsapparat bekannt, bei welchem eine Vielzahl von Reihen von Rollelementen nur aus Rollen **101** besteht, wie dies im Beispiel in **Fig.** 5(a) dargestellt ist.

Genauer gesagt, bei einem solchen Linearrollenführungsapparat ist ein beweglicher Block **103** entlang einer Führungsschiene **102** durch die Rollen **101**, **101**, **101**, **101** beweglich geführt, welche vorgesehen sind, um zwei Reihen von Rollen auf jeder der rechten und linken Seitenoberflächen der Führungsschiene **102** zu bilden, um insgesamt eine Anzahl von vier Reihen zu bilden.

Solch ein Vollrollentyp eines Linearführungsapparates hat jedoch Probleme, daß die auf die Rollen **101** aufgebrachte Vorspannung, eine inverse radiale Last (eine anhebende Last), die die Funktion eines Ziehens des beweglichen Blockes **103** weg von der oberen Oberfläche der Führungsschiene **102** hat, und eine Querlast, die die Funktion eines horizontalen Verschiebens des beweglichen Blockes **103** relativ zur Führungsschiene **102** hat, leicht verursachen kann, daß die rechten und linken Flügelbauteile **104**,**104** des beweglichen Blockes **103** in Richtung nach außen deformiert werden, so daß sie aufgrund des Momentes voneinander beabstandet sind. Solch eine Deformation der Flügelbauteile **104**, **104** macht es unmöglich, eine genaue Parallelität der Rollenlaufoberfläche **105** der Führungsschiene **102** und der Rollengegenlauffläche **106** des beweglichen Blockes **103**, zwischen welchen die Rollen gehalten sind, wie dies übertrieben in **Fig.** 5(b) dargestellt ist, beizubehalten. Entsprechend kann ein guter linearer Kontakt der Rolle **101** mit diesen Oberflächen **105**, **106** nicht beibehalten werden, mit dem Ergebnis, daß die Belastungskonzentration an dem Rollenende **101**a auftreten kann, wodurch die Belastungskapazität, wie auch die Haltbarkeit herabgesetzt wird, und es unmöglich wird, die Belastbarkeit der Rolle **101** vollständig auszunutzen.

Wenn eine Vorspannung z. B. auf die Rolle **101** aufgebracht wird, wie das in **Fig.** 5(c) dargestellt ist, werden die inneren Oberflächen der beiden Flügelbauteile des beweglichen Blockes **103** durch eine Reaktionskraft **104** des beweglichen Blockes **103** durch eine Reaktionskraft Fi der Vorspannung der Rolle **101** gedrückt und das Moment Mi, das die Funktion des Ausdehnens der Flügelbauteile **104**, **104** hat, wird erzeugt, was sich in einem Deformieren der Flügelbauteile **104**, **104** auswirkt.

Die inverse Radiallast Fu wird auf dem beweglichen Block **103** über einen Bolzen **108** aufgebracht, durch welchen ein Bauteil **107**, das geführt werden soll, an dem beweglichen Block **103** befestigt ist, wie dies in **Fig.** 5(d) dargestellt ist. Die unteren Rollen **101**, die auf den rechten und linken Seiten der Führungsschiene **102** angeordnet sind, nehmen die obengenannte Last Fu auf. Da der Bolzen **108**, auf welchem die Belastung aufgebracht wird, jedoch von der Rolle **101** in horizontaler Richtung beabstandet ist, bilden die inverse Radiallast Fu und die Reaktionskraft Nu des Kontaktabschnittes der Rolle **101** ein Kräftepaar, was sich in dem Auftreten des Momentes Mu auswirkt, das die Funktion des Ausdehnens der Flügelbauteile **104**, **104** hat, um eine Deformation der Flügelbauteile **104**, **104** hervorzurufen.

Die Querlast F_T wird auf dem beweglichen Block **103** durch den Bolzen **108** aufgebracht, wie dies in **Fig.** 5(e) dargestellt ist. Die beiden Reihen von Rollen **101**, die auf dem einen Flügelbauteil **104** angeordnet sind, nehmen die obengenannte Last F_T auf. Da der Bolzen **108**, auf welchem die Last aufgebracht wird, jedoch von der Rolle **101** in vertikaler Richtung beabstandet ist, hat das Moment M_T die Funktion des Ausdehnens des einen Flügelbauteiles **104**, um eine Deformation des Flügelbauteiles **104** hervorzurufen.

ZUSAMMENFASSUNG DER ERFINDUNG

Ein Ziel der vorliegenden Erfindung ist es daher, einen Linearführungsapparat für schwere Lasten bereitzustellen, der es erlaubt, eine genaue Linearbewegung des beweglichen Blockes beizubehalten, sogar wenn die Flügelbauteile des beweglichen Blockes deformiert sind.

Um das zuvor genannte Ziel zu erreichen, weist ein Linearführungsapparat auf:

eine Führungsschiene, die mit zwei Rollenlaufoberflächen, die auf der oberen Oberfläche der Führungsschiene ausgebildet sind und mit zwei Kugellaufnuten versehen sind, die auf jeder der Seitenoberflächen der Führungsschiene ausgebildet sind;

einen beweglichen Block, der mit einem horizontalen Bauteil versehen ist, das der oberen Oberfläche der Führungsschiene gegenüberliegt, und mit einem Paar von Flügelbauteilen, die jeweils den Seitenoberflächen der Führungsschiene gegenüberliegen, wobei das horizontale Bauteil an einer seiner Unterseiten zwei Rollenlaufgegenoberflächen aufweist, die den beiden Rollenlaufflächen der Führungsschiene entsprechen, und jedes der Flügelbauteile auf seiner inneren Oberfläche zwei Kugellaufgegennuten aufweist, die den beiden Kugellaufnuten der Führungsschiene entsprechen;

zwei Reihen von Rollen, die jeweils zwischen den beiden Rollenlaufoberflächen der oberen Oberfläche der Führungsschiene und den beiden Rollenlaufgegenoberflächen des horizontalen Bauteiles des beweglichen Blockes angeordnet sind, um rollbar zu sein; und

zwei Reihen von Kugeln zwischen den beiden Kugellaufnuten der Seitenoberflächen der Führungsschiene und den zwei Kugellaufgegennuten der inneren Oberflächen des Flügelbauteiles, jeweils in Lücken zwischen den Seitenoberflächen der Führungsschiene und den inneren Oberflächen des Flügelbauteiles, um rollbar zu sein.

Es wird bevorzugt, eine Struktur anzuwenden, bei der jede der Kugeln jeweils an zwei einander gegenüberliegenden Punkten von ihr in Kontakt mit der Kugellaufnut der Führungsschiene und der Kugellaufgegennut des beweglichen Blockes in Kontakt kommt, und eine Kontaktwinkellinie, die die beiden einander gegenüberliegenden Punkte miteinander verbindet, nach oben in Richtung zur Führungsschiene geneigt ist, in Beachtung der inversen Radiallast, die auf den beweglichen Block aufgebracht wird.

Bei der obengenannten vorliegenden Erfindung kann die radiale Last, die die Funktion des Pressens des horizontalen Bauteiles des beweglichen Blockes auf die Führungsschiene aufweist, im wesentlichen durch die zwei Reihen von Rollen aufgenommen werden, die auf der oberen Oberfläche der Führungsschiene angeordnet sind. Es ist daher möglich, einen Linearführungsapparat bereitzustellen, der eine geringere Größe aufweist und das Tragen schwerer Lasten erlaubt.

Die inverse Radiallast, die eine Funktion des Wegziehens des horizontalen Bauteiles des beweglichen Blockes von der oberen Oberfläche der Führungsschiene hat, kann durch die beiden Reihen von Kugeln aufgenommen werden, die auf jeder der Seitenoberflächen der Führungsschiene angeordnet sind.

Wenn die inverse Radiallast auf den beweglichen Block aufgebracht wird, ist es nicht möglich, eine Deformation der Flügelbauteile zu vermeiden, die durch das Moment hervorgerufen wird das die Funktion des Ausdehnens der Flügelbauteile hat. Sogar wenn die Flügelbauteile auf diese Weise deformiert sind, ist der Kontaktwinkel zwischen den Kontaktwinkellinien der Kugeln und der horizontalen Linie geringfügig geändert, ohne irgendwelche Probleme zu verursachen, da die Rollbauteile, die auf den Seitenoberflächen der Führungsschiene angeordnet sind, aus den Kugeln bestehen.

Die Querlast, die eine Funktion des Verschiebens des Flügelbauteiles des beweglichen Blockes relativ zur Seitenoberfläche der Führungsschiene aufweist, kann im wesentlichen durch die beiden Reihen von Kugeln aufgenommen werden, die auf der Seitenoberfläche der Führungsschiene angeordnet sind, und die Flügelbauteile werden deformiert aufgrund des Momentes, welches eine Funktion des Ausdehnens der Flügelbauteile hat. Sogar wenn die Flügelbauteile auf diese Weise deformiert werden, ist der Kontaktwinkel der Kugel geringfügig geändert, ohne irgendwelche Probleme zu verursachen, da die Rollbauteile, die auf den Seitenoberflächen der Führungsschiene angeordnet sind, aus den Kugeln bestehen.

Aufbringen der Vorspannung auf die Kugeln verursacht ein Deformieren der Flügelbauteile aufgrund des Momentes, welches eine Funktion des Ausdehnens der Flügelbauteile hat. Sogar wenn die Flügelbauteile auf diese Weise deformiert sind, ist der Kontaktwinkel der Kugel geringfügig geändert, ohne irgendwelche Probleme zu verursachen.

Sogar wenn die Flügelbauteile derart deformiert werden, um durch Aufbringen der inversen Radiallast oder der Querlast auf den beweglichen Block ausgedehnt werden, oder durch Aufbringen der Vorspannung auf die Kugeln in dieser Weise, wird der Kontaktwinkel der Kugel nur geringfügig geändert, so daß die Richtung der Last, welche auf den Kugeln getragen wird, ungefähr beigehalten wird. Die Kugeln können daher als Rollbauteile innerhalb ihrer Belastungskapazität dienen, und ein gleichmäßiges Laufen der Kugeln kann beibehalten werden. Spezieller, die Deformation der Flügelbauteile des beweglichen Blockes, die durch ein Aufbringen der radialen Gegenkraft hervorgerufen wird, kann absorbiert werden durch eine geringfügige Bewegung der Kontaktpunkte der Kugel gegenüber der Kugellaufnut und der Kugellaufgegennut (z. B. eine geringfügige Änderung des Kontaktwinkels der Kugel), und solche eine Deformation übt keinerlei Einfluß auf die Belastungskapazität der Kugel und ihren glatten Lauf aus.

Wenn das Moment, welches die Funktion des Ausdehnens der Flügelbauteile aufweist, erzeugt wird, wird das andere Moment, welches die Funktion des Ziehens des mittigen Abschnittes des horizontalen Bauteiles des beweglichen Blockes weg von dem im führenden Bauteil hat, simultan erzeugt. Das horizontale Bauteil des beweglichen Blockes neigt jedoch nicht dazu, durch solch ein Moment leicht verformt zu werden, da die obere Oberfläche des horizontalen Bauteiles fest mit dem zu führenden Bauteil verbunden ist. Als ein Ergebnis kann ein genauer Zustand beibehalten werden, in welchem die Rollen mit einem linearen Abschnitt ihres Randes in Kontakt mit der Rollenlaufgegenoberfläche kommen, die an der unteren Oberfläche des horizontalen Bauteiles des beweglichen Blockes ausgebildet ist, durch das Auftreten der Belastungskonzentration am Rollenende behindert wird.

Allgemein weist eine Rolle eine Belastungskapazität auf, die größer ist als die einer Kugel. Die innere Radialkraft kann von den vier Reihen von Kugeln aufgenommen werden, welche gebildet werden durch zwei Reihen von Kugeln, die auf einer Seitenoberfläche der Führungsschiene angeordnet sind, und die anderen beiden Reihen von Kugeln, die auf ihrer anderen Seitenoberfläche angeordnet sind. Die vier Reihen von Kugeln weisen die gleiche Belastungskapazität auf wie die beiden Reihen von Rollen, die die radialen Lasten aufnehmen. Zusätzlich kann die Querlast von den beiden Reihen von Kugeln aufgenommen werden, die eine hohe Festigkeit aufweisen, die jedoch nicht so groß ist wie die Belastungskapazität gegen die inverse Radiallast. Solche Reihen von Kugeln stellen genügend Belastungskapazität gegen die Lasten in vier Richtungen bereit, d. h. in radialer Richtung, in radialer Gegenrichtung, und in die rechten und linken Querrichtungen.

Insbesondere wenn die Belastungskapazität in radialer Richtung der Rolle derart vorherbestimmt ist, so daß sie zweimal oder dreimal so groß ist wie die Belastungskapazität in inverser Radialrichtung der Kugel, kann die Belastungskapazität für die inverser Radiallast, welche durch vier Reihen von Kugeln erhalten wird, derart eingestellt werden, um im wesentlichen gleich der Belastungskapazität für die radiale Belastung zu sein, welche durch die beiden Reihen von Kugeln aufgenommen wird. Obwohl die Belastungskapazität für die Querlast, welche nur durch die beiden Reihen von Kugeln aufgenommen wird, auf im wesentlichen die Hälfte der inversen Radiallast begrenzt ist, kann eine Struktur bereitgestellt werden, bei welcher die Lasten in vier Richtungen, d. h. in radialer Richtung, in inverser Radialrichtung, und in die rechten und linken Querrichtungen, ungefähr gleich zueinander gehalten werden können. Der Linearführungsapparat hat daher hervorragende Haltbarkeit gegen die Lasten in jede Richtung und kann unter beliebigen Bedingungen verwendet werden, um für verschiedene Zwecke verwendet zu werden.

Wenn der Linearführungsapparat als ein Führungsapparat für eine Werkzeugmaschine verwendet wird, wird der Arbeitstisch durch eine Vielzahl von beweglichen Blöcken gestützt. Sogar bei solche einer einfachen Führung in einer Ebene kann eine innere Radiallast auf einen der beweglichen Blöcke aufgebracht werden. Wenn eine gegebene Belastungskapazität für die innere Radiallast besteht, die im wesentlichen identisch zur Belastungskapazität für die Radialbelastung ist, ist es möglich, eine einfache Berechnung für die Haltbarkeit und die Lebensdauer durchzuführen, die für das Bestimmen der mechanischen Struktur nützlich ist.

Die vorliegende Erfindung weist auch das Merkmal auf, daß das horizontale Bauteil des beweglichen Blockes Bolzenlöcher aufweist, welche zwischen den beiden Reihen von Rollen, jeweils außerhalb jeder der beiden Reihen von Rollen angeordnet sind.

Eine Kraft, die die Funktion des Ausdehnens eines Flügelbauteiles, z. B., eine Vorgewinnung, die auf die Kugeln aufgebracht wird, oder die innere Radiallast oder die Querlast, die auf dem beweglichen Block simultan aufgebracht wird, ruft das Moment hervor, daß eine Funktion des Wegziehens des mittigen Abschnittes des horizontalen Bauteils des beweglichen Blockes weg von dem zu führenden Bauteil, wie z. B. ein Arbeitstisch oder dergleichen hat, um die Flügelbauteile wie oben erwähnt auszudehnen. Wenn ein mittiger Abschnitt des horizontalen Bauteiles des beweglichen Blockes an dem zu führenden Bauteil durch Bolzen befestigt ist, ist es möglich, das horizontale Bauteil daran zu hindern, deformiert zu werden, und das Auftreten des Problems zu verhindern, daß die Rolle nicht mit einem linearen Abschnitt an ihrem Rand mit der Rollenlaufgegenoberfläche in Kontakt kommt.

Die vorliegende Erfindung hat auch das Merkmal, daß jede der Kugellaufnut und der Kugellaufgegennut einen Kurvenradius aufweist, der geringer ist als ein Wert von 52% des Durchmessers der Kugel.

Gemäß diesem Merkmal kann Differenzialschlupf leicht auftreten, wodurch die Dämpfungskapazität verbessert wird.

KURZE BESCHREIBUNG DER ZEICHNUNGEN

Fig. 1(a) ist eine Frontquerschnittsansicht, welche einen Linearführungsapparat der ersten Ausführungsform der vorliegenden Erfindung darstellt, und**Fig.** 1(b) ist eine beschreibende Ansicht, welche einen Kontaktwinkel jeweils einer Rolle und einer Kugel darstellt;

Fig. 2(a) ist eine Seitenansicht, welche eine teilweise Schnittansicht des in **Fig.** 1(a) dargestellten Apparates zeigt **Fig.** 2(b) ist eine vergrößerte Querschnittsansicht, welche die Umgebung einer Richtungsänderungspassage, wie sie in **Fig.** 2(a) dargestellt ist, illustriert, in welcher die Kugeln weggelassen sind, 2(c) ist eine Draufsicht, welche einen teilweise Schnittansicht des in **Fig.** 1(a) dargestellten Apparates zeigt, und **Fig.** 2(d) ist eine vergrößerte Schnittansicht, welche die Umgebung der Richtungsänderungspassage, wie sie in **Fig.** 2(c) dargestellt ist, zeigt, bei welcher die Kugeln weggelassen sind;

Fig. 3(a) bis 3(h) sind beschreibende Darstellungen, welche einen Rollenverbinder und einen Kugelverbinder darstellen, welche bei dem in **Fig.** 1(a) dargestellten Apparat verwendet werden;

Fig. 4(a) bis 4(d) sind beschreibende Ansichten, welche den in **Fig.** 1(a) dargestellten Linearführungsapparat illustrieren, auf welchen die Last aufgebracht wird; und

Fig. 5(a) ist eine Schnittansicht, welche den konventionellen Linearführungsapparat darstellt, **Fig.** 5(b) ist eine beschreibende Ansicht, die übertrieben den Zustand darstellt, in welchem die Last auf ein Ende der Rolle aufgebracht wird, und **Fig.** 5(c) bis 5(e) sind beschreibende Ansichten, welche den konventionellen Linearführungsapparat darstellen, auf welchen die Last aufgebracht wird.

DETAILLIERTE BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSFORMEN

Nun werden Ausführungsformen des Linearführungsapparates der vorliegenden Erfindung im Detail mit Bezug auf die beigefügten Zeichnungen beschrieben.

Fig. 1 und 2 zeigen einen Linearführungsapparat einer Ausführungsform der vorliegenden Erfindung.

Die gesamte Struktur des Linearführungsapparates ist durch das Bezugszeichen **1** gekennzeichnet. Der Apparat **1** weist eine Führungsschiene **2**, einen beweglichen Block **3**, der derart angeordnet ist, um entlang der Führungsschiene **2** beweglich zu sein, zwei Reihen von Rollen **4**, die auf der oberen Oberfläche der Führungsschiene **2** angeordnet sind, und zwei Paar von zwei Reihen von Kugeln **5**, **6**; **5**, **6**, auf, wobei jedes Paar auf jeder der rechten und linken Seitenoberflächen der Führungsschiene **2** angeordnet ist.

Die Führungsschiene **2** weist einen rechtwinkligen Querschnitt auf. Zwei Rollenlaufoberflächen **41**, **41** sind auf die obere Oberfläche der Führungsschiene **2** ausgebildet, und zwei Kugellaufnuten **51**, **61** sind auf jede der rechten und linken Oberflächen der Führungsschiene **2** ausgebildet. Die zwei Rollenlaufoberflächen **41**, **41** sind in der Nähe der Seitenkanten der oberen Oberfläche der Führungsschiene **2** angeordnet. Die Führungsschiene **2** weist eine Vielzahl von Bolzenlöchern **7** auf zum Sichern der Führungsschiene **2**, die wie in dem mittleren Abschnitt der Führungsschiene **2** entlang einer geraden Linie ausgebildet sind, die sich in Längsrichtung der Führungsschiene **2** erstreckt.

Jede der Rollenlaufoberflächen **41**, **41** ist als eine flache horizontale Oberfläche ausgebildet. Jede der Kugellaufnuten **51**, **61**; **51**, **61** ist auf der anderen Seite als eine sogenannte Kreisbogennut ausgebildet, die eine konstante Krümmung im Querschnitt aufweist.

Der bewegliche Block **3** besteht aus einem horizontalen Bauteil **8**, welches der oberen Oberfläche der Führungsschiene **2** gegenüberliegt, und rechten und linken Flügelbauteilen **9**, **9**, welche sich nach unten von beiden Enden des horizontalen Bauteiles **8** aus erstrecken und den rechten und linken Seitenoberflächen der Führungsschiene **2** gegenüberliegen.

Das horizontale Bauteil des beweglichen Blockes **3** weist an seiner unteren Oberfläche zwei Rollenlaufgegenoberflächen **42**, **42** auf, welche den beiden Rollenlaufoberflächen **41**, **41** der Führungsschiene **2** entsprechen. Jedes der Flügelbauteile **9**, **9** der Führungsschiene **2** weist auf seiner inneren Oberfläche **2** Kugellaufgegennuten **52**, **62** auf, welche den beiden Kugellaufnuten **51**, **61** der Führungsschiene **2** entsprechen.

Jede der Rollenlaufgegenoberflächen **42**, **42** wird definiert durch die Bodenoberfläche jeder der Rollennuten **10**, **10**, welche auf der unteren Oberfläche des horizontalen Bauteiles **8** ausgebildet sind und weisen einen rechteckigen Querschnitt auf. Die Rollennut **10** weist die rechten und linken Seitenoberflächen auf, welche parallel zueinander sind und den beiden Enden der Rollen **4** gegenüberliegen, um eine extrem kleine Lücke zwischen den Seitenoberflächen der Rollennut **10** und den beiden Enden der Rolle **4** zu bilden. Solche Seitenoberflächen der Rollennut **10** bilden Rollenendenführungswände **10**a, **10**a. Die Rollennut **10** weist eine Tiefe auf, welche geringer ist als der Radius der Rolle, und in dem in den **Fig.** 1(a) und 1(b) gezeigten Beispiel ist die Tiefe der Rollennut **10** gleich der Hälfte des Radiuses der Rolle **4**.

Jede der beiden Kugellaufgegennuten **52**, **62** auf den inneren Oberflächen der Flügelbauteile **9**, **9** des bewegliches Blockes **3** ist ebenfalls als eine sogenannte Kreisbogennut ausgebildet, die eine konstante Krümmung in ihrem Querschnitt aufweist. Die Kugellaufnuten **51**, **61** der Führungsschiene **2** und die Kugellaufgegennuten **52**, **62** des beweglichen Blockes **3** können als eine sogenannte gotische Bogennut ausgebildet sein, bei welcher die innere Oberfläche durch zwei Bögen in ihrem Querschnitt gebildet wird.

Zwei Reihen von Rollen **4** sind zwischen den Rollenlaufoberflächen **41** der Führungsschiene **2** und den Rollenlaufgegenoberflächen **42** auf der unteren Oberfläche des horizontalen Bauteiles **8** des beweglichen Blockes **3** angeordnet, um darauf zu laufen. Zwei Reihen von Kugeln **5**, **6** sind zwischen den Kugellaufnuten **51**, **61** der Führungsschiene **2** und den Kugellaufgegennuten **52**, **62** auf der inneren Oberfläche der Flügelbauteile **9**, **9** des beweglichen Blockes **3** angeordnet, um darin zu laufen.

Wie in den **Fig.** 2(a) und 2(b) dargestellt, weist der bewegliche Block **3** einen Rollenrücklaufdurchgang **43** auf, in welchem keine Last auf die Rollen aufgebracht wird, um die Rollen **4** von einem Ende der Rollenlaufgegenoberfläche **42** zu ihrem anderen Ende zu fördern. Wie in den **Fig.** 2(c) und 2(d) dargestellt ist, weist der bewegliche Block **3** auch Kugelrückführdurchgänge **53**, **63** auf, in welchen keine Last auf die Kugeln aufgebracht wird, die zum Zirkulieren der Kugeln **5**, **6** von dem einen Ende der jeweiligen Kugellaufgegennuten **52**, **62** zu ihren anderen Enden vorgesehen sind.

Wie in den **Fig.** 2(a) und 2(b) dargestellt ist, besteht der Rollenrückführdurchgang **43** aus einem Rollenrückführloch **44**, welches parallel zur Rollenlaufoberfläche **41** als eine belastete Zone ausgebildet ist, um sich linear im beweglichen Block **3** zu erstrecken, und einem Paar von Richtungsänderungsdurchgängen **45**, **45** zum Verbinden der Enden der Rollenlaufoberfläche **41** mit den Enden des Rollenrückführloches **44**, um die Laufrichtung der Rollen entlang eines U-förmigen Durchganges zu ändern. Ein Laufdurchgang für belastete Rollen, der zwischen der Rollenlaufoberfläche **41** der Führungsschiene **2** und der Rollenlaufgegenoberfläche **42** des beweglichen Blockes **3** angeordnet ist, die Richtungsänderungsdurchgänge **45**, **45** und das Rollenrückführloch **44** bilden einen endlosen Zirkulierdurchgang.

Wie in **Fig.** 2(c) dargestellt ist, besteht der Kugelrückführduchgang **53** (**63**) aus einem Kugelrückführloch **54** (**64**), welches parallel zur Kugellaufgegennut **52** (**62**) ausgebildet ist, um sich linear in den beweglichen Block **3** hineinzuerstrecken, und einem Paar von Richtungsänderungsdurchgängen **55**, **55** (**65**, **65**) zum Verbinden der Enden der Kugellaufgegennut **52** (**62**) mit den Enden des Kugelrückführloches **54** (**64**), um die Laufrichtung der Kugel entlang eines U-förmigen Durchganges zu ändern. Ein Laufdurchgang für belastete Kugeln, der zwischen der Kugellaufnut **51** (**61**) der Führungsschiene **2** und der Kugellaufgegennut **52** (**62**) des beweglichen Blockes **3** ausgebildet ist, die Richtungsänderungsdurchgänge **55**, **55** (**65**; **65**) und das Kugelrückführloch **54** (**64**) bilden einen endlosen Zirkulationsdurchgang.

Der bewegliche Block **3** besteht aus einem metallischen Blockkörper **31** und Endplatten **32**, **32**, die an beiden Enden des Blockkörpers **31** befestigt sind. Die Rollenlaufgegenoberfläche **42** und das Rollenrückführloch **44** sind in einem horizontalen Bauteil **8** des Blockkörpers **31** ausgebildet. Die Kugellaufgegennuten **52**, **62** und die Kugelrückführlöcher **54**, **64** sind auf jedem der Flügelbauteile **9**, **9** des Blockkörpers **31** ausgebildet. Der Richtungsänderungsdurchgang **45** für die Rollen und die Richtungsänderungsdurchgänge **55**, **65** für die Kugeln sind in jeder der Endplatten **32** ausgebildet. Das Rollenrückführloch **44** erstreckt sich linear durch das horizontale Bauteil **8** des Blockkörpers **31**. Jedes der Kugelrückführlöcher **54**, **64** erstreckt sich linear durch jedes der Flügelbauteile **9**, **9** des Blockkörpers **31**.

Eine Vielzahl von Bolzenlöchern **33** sind auf dem oberen Abschnitt des Blockkörpers **31** des beweglichen Blockes **3** ausgebildet, der zwischen den beiden Reihen von Rollen **4** angeordnet ist, um in einer Linie ausgerichtet zu sein, die sich in einer Längsrichtung des beweglichen Blockes **3** erstreckt. Eine andere Vielzahl von Bolzenlöchern **33** ist auf dem oberen Abschnitt des Blockkörpers **31** ausgebildet, der dem Ursprung des einen Flügelbauteiles **9** entspricht und zwischen der Kugellaufgegennute **52** und dem Kugelrückführloch **54** angeordnet ist, um in einer Linie ausgerichtet zu sein, die sich in einer Längsrichtung des beweglichen Blockes **3** erstreckt. Eine weitere andere Vielzahl von Bolzenlöchern **33** ist auf dem oberen Abschnitt des Blockkörpers **31** ausgebildet, der dem Ursprung des anderen Flügelbauteiles **9** entspricht und zwischen der Kugellaufgegennut **52** und dem Kugelrückführloch **54** angeordnet ist, um in einer Linie ausgerichtet zu sein, die sich in einer Längsrichtung des beweglichen Blockes **3** erstreckt.

Ein Rollenkontaktwinkel $\alpha 1$ zwischen einer horizontalen Linie H1, die sich durch eine mittige Achse der Rolle erstreckt, und eine Kontaktwinkellinie S1, welche identisch mit einer normalen Linie zur Rollenlaufoberfläche **41** ist (oder der Rollenlaufgegenoberfläche **42**) werden derart beibehalten, daß sie im wesentlichen gleich 90 Grad sind. Das Rollenrückführloch **44** ist auf der obengenannten Kontaktwinkellinie S1 der Rolle **4** angeordnet. Die Rolle **4** kann in einem geneigten Zustand angeordnet sein, so daß ihre mittige Achse die horizontale Linie schneidet. Die Rollen **4** sind nicht auf den obenbeschriebenen zylindrischen Typ beschränkt, der einen konstanten Durchmesser aufweist, die auf einer flachen Oberfläche laufen, sondern können einen Durchmesser aufweisen, der in einer Längsrichtung der Rolle variiert.

Mit Bezug auf die Kontaktstruktur der Kugel **5**, **6** mit den Kugellaufnuten **51**, **61** und den Kugellaufgegennuten **52**, **62**, wie dies in **Fig.** 1(b) dargestellt ist, gelangt die Kugel **5** (**6**) jeweils an zwei einander gegenüberliegenden Punkten von ihr in Kontakt mit der Kugellaufnut **51**(**61**) und der Kugellaufgegennut **52**, **62**. Eine Kontaktwinkellinie S2 (S3), die die obengenannten beiden einander gegenüberliegenden Punkte miteinander verbindet, neigt sich nach oben in Richtung zum mittigen Abschnitt der Führungsschiene **2** relativ zur horizontalen Linie H2 (H3), die sich durch ein Zentrum der Kugel **5** (**6**) erstreckt. Das Kugelrückführloch **54** (**64**) ist auf der gleichen Höhe wie die Kugellaufgegennut **52** (**62**) angeordnet, und ist nämlich auf der horizontalen Linie H2 (H3) angeordnet.

Der Kontaktwinkel $\alpha 2$ zwischen der Kontaktwinkellinie S2 und der horizontalen Linie H2 ist identisch zum Kontaktwinkel $\alpha 3$ zwischen der Kontaktwinkellinie S3 und der Horizontallinie H3. Diese Kontaktwinkel $\alpha 2$ und $\alpha 3$ werden derart beibehalten, so daß sie im wesentlichen identisch 45 Grad bei der Ausführungsform der vorliegenden Erfindung sind.

Die Kontaktwinkel $\alpha 2$ und $\alpha 3$ sind nicht auf die oben beschriebenen Winkel von 45 Grad beschränkt sondern können z. B. im Bereich von 30 bis 60 Grad liegen. Die Kontaktwinkel $\alpha 2$ und $\alpha 3$ sind relativ groß und die Kugelführungsnuten **51**, **52** und die Kugelführungsgegennuten **61**, **62** weisen eine große Tiefe auf.

Es wird bevorzugt, den Krümmungsradius jeder der Kugellaufnuten **51**, **61** und der Kugellaufgegennuten **52**, **62** innerhalb eines Bereiches von über 50 bis unter 52% des Durchmessers der Kugeln **5**, **6** zu halten. Ein noch mehr bevorzugter Wert des obengenannten Krümmungsradius, ist ungefähr 51% des Durchmessers der Kugeln **5**, **6**. Solch eine Konstruktion ermöglicht, daß ein Differenzialschlupf leicht auftreten kann, wodurch die Dämpfungsfähigkeit verbessert wird. In dieser Ausführungsform ist der Durchmesser der Kugeln **5**, **6** identisch zueinander und die Krümmungsradien der Kugellaufnuten **51**, **61** und der Kugellaufgegennuten **52**, **62** sind auch identisch zueinander.

Die Kugel **5** (**6**) weist einen Durchmesser auf, der größer ist als der Abstand zwischen der Kugellaufnut **51**(**61**) und der Kugellaufgegennut **52** (**62**), so daß eine Vorspannung auf die Kugel **5** (**6**) aufgebracht wird. Eine Vorspannung wird auch auf die Rolle **4** aufgebracht und die Kugeln **5**, **6** nehmen die Reaktionskraft der Vorspannung auf, die auf die Rolle **4** aufgebracht wird. Spezieller wird die Reaktionskraft der Vorspannung, die die Funktion des Wegziehens des horizontalen Bauteiles weg von der Führungsschiene **2** aufweist, welche Kraft durch die Rolle **4** gegeben wird, mit einer vertikalen Komponente der Reaktionskraft der Vorspannung ausgeglichen, die auf die Kontaktpunkte der Kugeln **5** (**6**) mit der Kugellaufnut **51**(**61**) und der Kugellaufgegennut **52** (**62**) in einer Richtung der Kontaktwinkellinie S2 (S3) aufgebracht wird, so daß der vorgeschriebene Kontaktwinkel $\alpha 2$ ($\alpha 3$) beibehalten wird. Mit anderen Worten können die Kontaktwinkel $\alpha 2$, $\alpha 3$ durch nach oben verlagern der Position der Kugellaufgegennuten **52** (**62**) der Flügelbauteile **9**, **9** des beweglichen Blockes **3** relativ zu den Kugellaufnuten **51**, **61** der Führungsschiene **2** durch die Rollen **4** bestimmt werden, die angeordnet sind, um zwischen der oberen Oberfläche der Führungsschiene **2** und dem horizontalen Bauteil **8** des beweglichen Blockes **3** zu rollen.

Die Reaktionskraft der Vorspannung, die auf die Kugeln **5, 6; 5, 6** aufgebracht wird, verursacht, daß das Moment, das auf die Flügelbauteile **9, 9** aufgebracht wird, die Flügelbauteile **9, 9** geringfügig ausdehnt, was in einem geringfügigen Verschieben der Kugeln **5, 6** in den Kugellaufnuten **51, 61** und den Kugellaufgegennuten **52, 62** resultiert. Der Kontaktwinkel $\alpha 2$ (α) wird in einem Zustand bestimmt, in dem die Vorspannung auf diese Weise aufgebracht wurde. Nach dem Bestimmen des vorgeschriebenen Kontaktwinkels der Kugeln **5, 6** kann ein tatsächliches Aufbringen der Vorspannung durchgeführt werden. In diesem Fall wird der Kontaktwinkel $\alpha 2$ ($\alpha 3$) geringfügig geändert und es ist trotzdem keine Störung der Belastungskapazität vorhanden.

In einem Ort, auf welchen keine Hebelast aufgebracht wird und nur die Radiallast und die Querlast aufgebracht wird, kann der Kontaktwinkel $\alpha 2$ ($\alpha 3$) mit Null Grad bestimmt werden. Es kann auch eine Struktur verwendet werden, bei der die Kontaktwinkel $\alpha 2$, $\alpha 3$ graduell abnehmen, so daß die Kontaktwinkellinien S2, S3 graduell näher zur Mitte der Führungsschiene liegen, entsprechend dem Bewegen der Kugeln **5, 6** in Längsrichtung der Führungsschiene **2**. Die Kontaktwinkel $\alpha 2$, $\alpha 3$ können bestimmt werden, um verschieden voneinander zu sein.

Wie in **Fig.** 2 dargestellt ist, in dieser Ausführungsform, sind die Rollen **4** miteinander in der Form einer Kette verbunden durch einen flexiblen Rollenverbinder **40**, und die Kugeln **5, 6** sind auch miteinander verbunden in der Form einer Kelle jeweils durch flexible Kugelverbinder **50, 60**.

Wie in den **Fig.** 3(a) bis 3(c) dargestellt ist, besteht der Rollenverbinder **40** aus einem Paar von-flexiblen Bändern **40**b und einer Vielzahl von Abstandsabschnitten **40**c, von denen jeder zwischen den flexiblen Bändern **40**b angeordnet ist. Die benachbarten zwei Abstandsabschnitte **40**c, **40**c bilden ein Rollenloch **40**a, in welchem die Rolle **4** aufgenommen ist. Die Kontaktoberfläche des Abstandsabschnittes **40**c mit der Rolle **4** ist in einer konkaven Form ausgebildet, welche der zylindrischen Umfangsoberfläche der Rolle **4** entspricht, so daß die Rolle **4** zwischen den zwei benachbarten Abstandsabschnitten **40**c, **40**c gehalten werden kann.

Wie in den **Fig.** 3(e) bis 33(g) dargestellt ist, bestehen die Kugelverbinder **50** (**60**) aus einem Paar von flexiblen Bändern **50**b (**60**b) und einer Vielzahl von Abstandsabschnitten **50**c (**60**c), von denen jeder zwischen den flexiblen Bändern **50**b (**60**b) angeordnet ist. Die benachbarten beiden Abstandsabschnitte **50**c, **50**c (**60**c, **60**c) bilden ein Kugelloch **50**a (**60**a), in welchem die Kugel **5** (**6**) aufgenommen ist. Die Kontaktoberfläche des Abstandsabschnittes **50**c (**60**c) mit der Kugel **5** (**6**) ist konkavförmig ausgebildet, was der sphärischen Oberfläche der Kugel **5** (**6**) entspricht, so daß die Kugel **5** (**6**) zwischen den beiden benachbarten Abstandsabschnitten **50**c, **50**c (**60**c, **60**c) gehalten werden kann.

Jeder der obenbeschriebenen Rollenverbinder **40** und der Kugelverbinder **50** (**60**) weist einander gegenüberliegende Abschnitte auf, wodurch sich ein streifenförmiges Band ergibt. Diese Verbinder **40, 50** (**60**) können jedoch als endloses Band ausgebildet sein durch Verbinden ihrer einander gegenüberliegenden Endabschnitte miteinander.

Der Rollenverbinder **40** oder der Kugelverbinder **50** (**60**) hat die fundamentale Funktion dafür zu sorgen, daß die Rolle **4** oder die Kugeln **5, 6** sanft und gleichmäßig rollen.

Das Rollen der Rolle **4** wird nachfolgend als Beispiel erklärt. Wenn der bewegliche Block **3** entlang der Führungsschiene **2** bewegt wird, werden die Rollen **4**, die zwischen der Rollenlaufoberfläche **41** und der Rollenlaufgegenoberfläche **42** in der belasteten Zone angeordnet sind, gerollt, um auf der Rollenlaufoberfläche **41** der Führungsschiene **2** in Bewegungsrichtung des beweglichen Blockes **3** zu rollen, während die Rollen **4** durch den Rollenverbinder **40** zurückhalten werden. Eine der Rollen **4** wird herausgedrückt aus dem hinteren Ende der Rollenlaufgegenoberfläche **42** des Blockkörpers **31** zum Richtungsänderungsdurchgang **45** als ein nicht belasteter Bereich. Die derart herausgedrückte Rolle **4** tritt in das Rollenrückführloch **44** von seinem hinteren Ende her ein und wird dann geschoben, um in Bewegungsrichtung des beweglichen Blockes **3** zu laufen. Die geschobene Rolle **4** bewegt sich vom vorderen Ende des Rollenrückführloches **44** zum Richtungsänderungsdurchgang **45** und bewegt sich dann vom vorderen Ende des beweglichen Blockes zur Rollenlaufoberfläche **41** und der Rollenlaufgegenoberfläche **42**.

Wenn der Rollenverbinder **40** nicht verwendet wird, werden die Rollen **3** im Rollenrückführdurchgang **43** hintereinander geschoben, um in das vordere Ende der Rollenlaufgegenoberfläche **42** durch den Druck der Rolle **3** einzutreten, die vom hinteren Ende der Rollenlaufoberfläche **41** und der Rollenlaufgegenoberfläche **42** als belastete Zone herausgedrückt wird. Wenn der Rollenverbinder **40** verwendet wird, sind die Rollen **4** beabstandet voneinander durch die Abstandsabschnitte **40**c, mit dem Ergebnis, daß die Rollen **4** herausgedrückt werden, ohne miteinander zu kollidieren, während sie fluchtend zueinander ausgerichtet durch den Rollenverbinder **40** gehalten werden. Die Rollen **4** werden sequentiell in das vordere Ende der Rollenlaufoberfläche **41** und der Rollenlaufgegenoberfläche **42** als belastete Zone durch den Rollenverbinder **40** hereingezogen, wodurch ein sanfter Übergang der Rollen **4** in die belastete Zone möglich wird. Die Kugelverbinder **50, 60** haben die gleiche Funktion wie die der obenbeschriebenen Rollenverbinder **40**.

Ein Rollenverbinder-Rückhaltebauteil **46** zum Führen des Rollenverbinders **40** ist auf dem in Längsrichtung einander gegenüberliegenden Ecken der Rollenlaufgegenoberfläche **42** als die belastete Zone auf der unteren Oberfläche des horizontalen Bauteiles **8** des Blockkörpers **31** ausgebildet, wie dies in **Fig.** 1(a) und **Fig.** 3(d) dargestellt ist. Kugelverbinder-Rückhaltebauteile **56, 66** zum Führen der Kugelverbinder **50, 60** sind auf den in Längsrichtung an der gegenüberliegenden Ecken der Kugellaufgegennuten **52, 62**, die auf den jeweilig inneren Oberflächen der Flügelbauteile **9, 9** ausgebildet sind, angeordnet, wie dies in **Fig.** 1(a) und **Fig.** 3(h) dargestellt ist.

Das Rollenverbinder-Rückhaltebauteil **46** besteht aus Kunstharz, um integral mit der unteren Oberfläche des horizontalen Bauteiles **8** des Blockkörpers **31** ausgebildet zu sein. Das Rollenverbinder-Rückhaltebauteil **35** ist mit einem Paar von Führungsnuten **47, 47** versehen, in welches die Seitenkantenabschnitte des Bandes **40**b, welche gegenüber beiden Enden der Rolle **4** vorstehen, eingesetzt werden. In dem in den **Fig.** 1(a) und **Fig.** 3(d) dargestellten Beispiel wird ein aus Kunstharz geformter Körper verwendet, der Führungsnuten **47, 47** aufweist.

Wie in **Fig.** 2(b) dargestellt, sind ein weiteres Paar von Führungsnuten **47, 47** zum Führen der Seitenkantenabschnitte des Rollenverbinders **40** ebenso kontinuierlich in den Richtungsänderungsdurchgang **44** für die Rollen und dem Rollenrückführloch **45** als nicht belastete Zonen ausgebildet.

Das Rollenverbinderrückhaltebauteil **46** verhindert, daß der Rollenverbinder **40** von dem beweglichen Block **3** absinkt, wenn der bewegliche Block **3** von der Führungsschiene **2** entfernt wird. Die Abstandsabschnitte **40**c, **40**c des Rollenverbinders **40** verhindern, daß Rollen vom Rollenverbinder **40** abfallen.

Gemäß einem konventionellen Verfahren werden die Rollen an ihren sich verjüngenden Umfangsendkanten durch einen Rückhalter gehalten, um zu verhindern, daß die Rollen vom Rückhalter abfallen. In solch einem Fall ist die Länge der Kontaktabschnitte der Rolle mit der Rollenlaufoberfläche durch die Gesamtlänge der sich verjüngenden Endkanten verringern, wodurch die Belastungskapazität reduziert wird. Die Konstruktion, die auf dieser Ausführungsform basiert, daß der Rollenverbinder **40** durch das Rollenverbinder-Rückhaltebauteil **46** zurückgehalten wird und der Rollenverbinder **40** verhindert, daß die Rollen **4** aus dem Rollenverbinder **40** herausfallen, erlaubt das effektive Benutzen der gesamten Länge der Rolle, wodurch das Reduzieren der Belastungskapazität verhindert wird.

Das Kugelverbinder-Rückhaltebauteil **56** (**66**) besteht aus Kunstharz, um integral mit der inneren Oberfläche des Flügelbauteiles **9** des Blockkörpers **31** ausgebildet zu sein. Das Kugelverbinder-Rückhaltebauteil **56** (**66**) ist mit einem Paar von Führungsnuten **57**, **57** (**67**, **67**) versehen, in welchen die Seitenkantenabschnitte des Bandes **50**b (**60**b), die gegenüber beiden Enden der Kugeln **5** (**6**) vorstehen, eingesetzt werden. In dem in **Fig.** 1(a) und **Fig.** 3(h) dargestellten Beispiel werden die Führungsnuten **57**, **57** (**67**, **67**) durch den metallischen Blockkörper **31** gebildet.

Wie in **Fig.** 2(d) dargestellt, wird ein weiteres Paar von Führungsnuten **57**, **57** (**67**, **67**) zum Führen der Seiteneckabschnitte des Kugelverbinders **50** (**60**) ebenfalls kontinuierlich auf dem Kugelrückführloch **54** (**64**) und dem Richtungsänderungsdurchgang **55** (**65**) für die Kugeln als nicht belastete Zonen ausgebildet.

Das Kugelverbinder-Rückhaltebauteil **56** (**66**) verhindert auch, daß der Kugelverbinder **50** (**60**) von dem beweglichen Block **3** absinkt, wenn der bewegliche Block **3** von der Führungsschiene **2** entfernt wird. Die Abstandsabschnitte **50**c, **50**c (**60**c, **60**c) des Kugelverbinders **50** (**60**) hindern die Kugeln **5** (**6**) vom Herausfallen aus dem Kugelverbinder **50** (**60**). Der Abstand zwischen jeder der Seitenoberflächen der Führungsschiene **2** und der inneren Oberfläche jedes der Flügelbauteile **9**, **9** des beweglichen Blockes **3** ist kleiner als der Durchmesser eines Kreises, der durch zwei benachbarte Abstandsabschnitte **50**c, **50**c (**60**c, **60**c) gebildet wird, so daß die Tiefe jeder der Kugelführungsnuten **51**, **61** und der Kugelführungsgegennuten **52**, **62** so tief wie möglich ausgebildet wird, wodurch die Kontaktwinkel $\alpha 2$, $\alpha 3$ vergrößert werden.

Ein Linearbewegungsführungsapparat, der die obenbeschriebene Struktur aufweist, wird unter einer Bedingung verwendet, daß die Führungsschiene **2** an einer Basis **12** durch Bolzen **11** gesichert ist, ein zu führendes Bauteil **13** wie z. B. ein Tisch ist an der oberen Oberfläche des beweglichen Blockes **3** durch Bolzen **14**a, **14**b, **14**c, wie in **Fig.** 4 dargestellt, gesichert.

Die **Fig.** 4(a) bis 4(d) sind beschreibende Ansichten, welche den Linearführungsapparat darstellen, auf welchen Belastungen in verschiedene Richtungen aufgebracht werden.

Wenn eine Radiallast F_R, die die Funktion des Drückens des beweglichen Blockes **3** gegen die Führungsschiene **2** hat, aufgebracht wird, wie dies in **Fig.** 4(a) dargestellt ist, wird die Radiallast F_R von den Rollen **4**, **4** aufgenommen, die eine hohe Festigkeit aufweisen. Eine schwere Last in radialer Richtung kann durch diese Rollen **4**, **4** abgestützt werden. In dieser Ausführungsform kann die hohe Festigkeit der Rollen **4**, **4** vollständig genutzt werden, da der Kontaktwinkel $\alpha 1$ 90 Grad beträgt und die Rollen durch den Rollenverbinder **40** zurückgehalten werden, so daß die Kontaktlänge der Rollen **4** mit der Rollenlaufoberfläche **41** und der Rollenlaufgegenoberfläche **42** im wesentlichen identisch zur Gesamtlänge der Rolle **4** ist. Die Kugeln **5**, **6**; **5**, **6** nehmen keine Radiallast auf, wie oben beschrieben, aufgrund des genau beibehaltenen Kontaktwinkels.

Fig. 4(b) stellt einen Zustand dar, in welchem eine inverse Radiallast F_u, die die Funktion des Wegziehens des beweglichen Blockes **3** von der Führungsschiene **2** hat, aufgebracht wird. Diese inverse Radiallast F_u von den vier Reihen von Kugeln **5**, **6**; **5**, **6** aufgenommen.

Wenn die inverse Radiallast Fu auf den beweglichen Block aufgebracht wird, da die Kugeln **14**a, **14**c, durch welche der bewegliche Block **3** an dem zu führenden Bauteil **13** befestigt ist, von den Kugeln **5**, **6** in horizontaler Richtung beabstandet sind, bilden die inverse Radiallast F_u (d. h. die anhebende Last), die durch die Bolzen **14**a, **14**c aufgebracht wird, und die Reaktionskraft Nu des Kontaktabschnittes der Kugeln **5**, **6** ein Kräftepaar, was zum Auftreten des Momentes Mu führt, daß die Funktion des Ausdehnens der Flügelbauteile **9**, **9** hat, um eine Deformation der Flügelbauteile **9**, **9** hervorzurufen. Sogar wenn die Flügelbauteile **9**, **9** auf diese Weise ausgedehnt werden, werden die Kontaktwinkel $\alpha 2$, $\alpha 3$ kaum geändert, wodurch kein Problem verursacht wird, da das was auf der Innenoberfläche des Flügelbauteiles **9** angeordnet ist, die Kugeln **5**, **6** sind. Spezieller gesagt wird das relative Versetzen der Kugellaufgegennuten **52**, **62** zu den Kugellaufnuten **51**, **61** durch das Verschieben der Kontaktpunkte der Kugeln **5**, **6** mit diesen Nuten absorbiert.

Das obengenannte Moment Mu verursacht das Erzeugen einer Kraft, die die Funktion des Wegziehens des mittigen Abschnittes des horizontalen Bauteiles **8** des beweglichen Blockes **3** weg vom zu führenden Bauteil **13** hat. Die Rollenlaufgegenoberfläche **41** des horizontalen Bauteiles **8** wird jedoch horizontal gehalten, ohne eine Änderung der Kontaktbedingung der Rolle **4** hervorzurufen, da der mittige Abschnitt des horizontalen Bauteiles **8** an den zuführenden Bauteil **13** gesichert ist durch die Bolzen **14**b. Es ist daher möglich, einen Zustand beizubehalten, in dem die Rolle **4** an ihrem längs verlaufenen Linearabschnitt in Kontakt mit der Rollenlaufgegenoberfläche **41** kommt, die auf der unteren Oberfläche des horizontalen Bauteiles **8** angeformt ist, wodurch das Auftreten eine Belastungskonzentration am Ende der Rolle **4** verhindert wird.

Fig. 4(c) stellt einen Zustand dar, in welchem eine Querlast F_T, die die Funktion des Drückens des beweglichen Blockes **3** quer gegen die Führungsschiene **2** aufweist, aufgebracht wird. Die Querlast F_T wird von dem zu führenden Bauteil **13** auf den beweglichen Block **3** durch den Bolzen **14** aufgebracht. Die Querlast F_T wird von den beiden Reihen von Kugeln **5**, **6** pro Seite aufgenommen. Da die Querlast F_T auf den beweglichen Block **3** über die Bolzen **14** aufgebracht wird, bildet die Reaktionskraft, die auf die Kugeln **5**, **6** aufgebracht wird, ein Kräftepaar, um ein Moment M_T zu erzeugen, das die Funktion des Auseinanderdrückens der Flügelbauteilen **9** nach außen in der Nähe des Verbindungsabschnittes des Bolzens als mittigen Punkt hat, was sich in einem geringfügigen Ausdehnen der Flügelbauteile **9** äußert. Sogar wenn das Flügelbauteil **9** auf diese Weise auseinandergedrückt wird, tritt leichtes Versetzen der Kugeln **5**, **6** in den Kugellaufbahnen **51**, **61** und den Kugellaufgegennuten **52**, **62** auf, und die Kontaktwinkel $\alpha 2$, $\alpha 3$ werden kaum geändert, wodurch kein Problem verursacht wird, da das was auf der Innenoberfläche des Flügelbauteiles **9** angeordnet ist, die Kugeln **5**, **6** sind. Spezieller gesagt, wird ein relatives Verschieben der Kugellaufgegennuten **52**, **62** zu den Kugellaufnuten **51**, **61** absorbiert durch das Verschieben der Kontaktpunkte der Kugeln **5**, **6** gegenüber dieser Nuten.

Das obengenannte Moment N_T wird verursacht durch das Erzeugen einer Kraft, die die Funktion des Wegziehens des mittigen Abschnittes des horizontalen Bauteiles **8** des beweglichen Blockes **3** weg von dem zu führenden Bauteil **13** hat. Die Deformation des horizontalen Bauteiles **8** tritt jedoch nicht auf, da der mittige Abschnitt des horizontalen

Bauteiles **8** an dem zuführenden Bauteil **13** ist durch die Bolzen **14** gesichert. Es ist daher möglich, die Rollenlaufgegenoberfläche **42** horizontal zu halten, die an der unteren Oberfläche des horizontalen Bauteiles **8** angeordnet ist, ohne ein Variieren der Kontaktbedingung der Rolle **4**.

Sogar wenn die Deformation des Flügelbauteiles **9**, **9** in dieser Weise auftritt aufgrund des Aufbringens einer inversen Radiallast FU oder der Querlast F_T auf den beweglichen Block **3**, oder das Aufbringen der Vorspannung auf die Kugeln **5**, **6**, werden die Kontaktwinkel $\alpha 2$, $\alpha 3$ kaum geändert, wodurch ein Beibehalten der Richtung der Last, welche durch die Kugeln **5**, **6** aufgenommen wird, beibehalten wird. Die Belastungskapazität der Kugeln **5**, **6** wird daher nicht geändert und ein gleichmäßiger Lauf der Kugeln **5**, **6** wird auch beibehalten. Spezieller gesagt, sogar wenn die Flügelbauteile **9**, **9** durch die inverse Radiallast Fu deformiert werden, werden solche Deformationen durch die geringfügige Verschiebung der Kontaktpunkte der Kugeln **5**, **6** (d. h. die kleine Änderung des Kontaktwinkels), absorbiert, ohne irgend einen Einfluß auf die Belastungskapazität und das gleichmäßige Laufen der Kugeln **5**, **6** auszuüben.

Im allgemeinen weist die Rolle **4** eine Belastungskapazität auf, die größer ist als die der Kugeln **5**, **6**. Wenn die Belastungskapazität in radialer Richtung der Rolle **4** derart bestimmt wird, da sie zwei- bis dreimal so groß wie die Belastungskapazität in der inversen Radialrichtung der Kugeln **5**, **6** ist, und zwei Reihen von Kugeln **5**, **6**, die die inverse Last (die hebende Last) und die Querlast tragen, auf jeden der Flügelbauteile angeordnet sind, kann eine lasttragende Struktur erhalten werden, in welcher die Lasten in den vier Richtungen (d. h. die radiale Richtung, die inverse radiale Richtung, und die rechten und linken Richtungen) ungefähr gleich zueinander sind. Die Linearführungsvorrichtung weist daher eine exzellente Haltbarkeit gegen Belastungen aus jeglichen Richtungen auf, und kann unter jeglichen Bedingungen verwendet werden, um für verschiedene Anwendungen benutzt werden zu können.

Spezieller gesagt, wird die Radiallast von zwei Reihen von Rollen **4** aufgenommen, wird die inverse Radiallast Fu von zwei Reihen von Kugeln **5**, **6**; **5**, **6** aufgenommen, die jeweils auf den Flügelbauteilen angeordnet sind, um eine Gesamtzahl von vier Reihen zu bilden, und die Querlast F_T wird von den jeweiligen zwei Reihen von Kugeln **5**, **6** pro Seite der Führungsschiene **2** aufgenommen. Entsprechend kann die Radiallast F_R und inverse Radiallast Fu gleichmäßig aufgenommen werden. Die Querlasten F_T in Rechts- und Linksrichtung können gleichmäßig getragen werden, obwohl die Belastungskapazität für jede der Querlasten halbiert wird.

Mit Bezug auf die Rollrichtungsdrehmomentbelastung, die die Funktion des Ausschwingens des beweglichen Blokkes **3** hat, wobei die Längsachse der Führungsschiene **2** als Achse für das Rollen dient, kann solche eine Belastung gleichmäßig an den rechten und linken Seiten durch die einzelnen Reihen von Rollen **4** und die beiden Reihen von Kugeln **5**, **6** pro Seite aufgenommen werden.

Mit Bezug auf die Kippmomentbelastung, die die Funktion des Schwingens des vorderen Endes des beweglichen Blockes **3** nach oben und unten zur Horizontalachse hat, die die Längsachse des beweglichen Blockes **3** im rechten Winkel als Kippachse schneidet, kann die Radiallast (d. h. die Hebelast), die auf irgendeine der vorderen oder hinteren Enden des beweglichen Blockes **3** aufgebracht wird, durch die vier Reihen von Kugeln **5**, **6**; **5**, **6** aufgenommen werden, die zwei Reihen von Kugeln **5**, **6** aufweisen, die auf jede der rechten und linken Seiten der Führungsschiene **2** angeordnet sind. Die Radiallast, die auf die anderen der vorderen und hinteren Enden des beweglichen Blockes aufgebracht werden, können gleichmäßig von den zwei Reihen von Rollen **4**, **4** aufgenommen werden.

Bezüglich einer Gierdrehmomentlast, die die Funktion des Schwingens des vorderen Endes des beweglichen Blokkes **3** nach rechts und links um eine vertikale Achse hat, die die Längsachse des beweglichen Blockes **3** im rechten Winkel als Gierachse schneidet, kann die Querlast, die auf irgendeine der vorderen und hinteren Enden des beweglichen Blockes **3** aufgebracht wird, von den beiden Reihen von Kugeln **5**, **6** aufgenommen werden, die auf jeder der rechten und linken Seiten der Führungsschiene **2** angeordnet sind. Die Querlast, die auf das andere vordere und hintere Ende des beweglichen Blockes **3** aufgebracht wird, kann gleichmäßig auf die von den anderen beiden Reihen von Kugeln **5**, **6** aufgenommen werden, die auf den anderen rechtend und linken Seiten der Führungsschiene **2** angeordnet sind.

Der Linearführungsapparat hat daher exzellente Haltbarkeitseigenschaften gegen Belastungen in jegliche Richtungen, und kann unter beliebigen Bedingungen verwendet werden, um für verschiedene Zwecke auf diese Weise eingesetzt werden zu können.

Fig. 4(d) stellt den Linearführungsapparat beispielhaft dar, der als Führungsapparat für eine Werkzeugmaschine verwendet wird.

Eine Vielzahl von beweglichen Blöcken **3**, **3**, **3**, **3** ist verschieblich auf einem Paar von Führungsschienen **2**, **2** angeordnet, die an einer Schiene **201** befestigt sind, um parallel zueinander zu sein. Ein Arbeitstisch **200** ist an den beweglichen Blöcken **3**, **3**, **3**, **3** befestigt, um linear durch einen Zustellmechanismus, wie z. B. eine Kugelrollspindel bewegt zu werden. Ein Arbeitsstück **203** ist stationär auf dem Arbeitstisch **200** angeordnet, so daß ein Bearbeiten, wie z. B. ein Fräsen an dem Werkstück **203** durch ein Werkzeug **205** durchgeführt werden kann, das stationär auf einer Spindel **204** gehalten ist.

In solch einem Fall, wo der Linearführungsapparat zum Führen des Arbeitstisches **200** verwendet wird, verursacht das Aufbringen einer horizontal gerichteten Kraft des Werkzeuges **205** auf das Werkstück **203** z. B. eine Reaktionskraft, die erzeugt wird, so daß die Radiallast F_R auf einige der beweglichen Blöcke **3**, **3** aufgebracht wird, und die inverse Radiallast Fu auf die anderen beweglichen Blöcke **3**, **3** aufgebracht wird. Nicht nur die Radiallast F_R, sondern auch die inverse Radiallast Fu der Querbelastung F_T wird auch die beweglichen Blöcke **3**, **3**, **3**, **3** in dieser Weise aufgebracht. Wenn der Linearführungsapparat eine Struktur hat, in welcher die Belastungen in die vier Richtungen, d. h., die Radialrichtung, die inverse Radialrichtung und die rechten und linken Querrichtungen, ungefähr gleich zueinander gehalten werden, ist es möglich, eine einfache Berechnung für Festigkeit und Lebensdauer durchzuführen, die nützlich ist, um die mechanische Struktur zu bestimmen.

Gemäß der vorliegenden Erfindung, wie im Detail beschrieben, ist es möglich, schwere Lasten in radialer Richtung durch Anordnen zweier Reihen von Rollen zwischen der oberen Oberfläche der Führungsschiene und der unteren Oberfläche des horizontalen Bauteiles des beweglichen Blockes aufzunehmen, und die schweren Lasten in Querrichtung und inverser Radialrichtung durch Anordnen zweier Reihen von Rollen auf jeder der rechten und linken Seiten der Führungsschiene aufzunehmen.

Sogar wenn die Führungsbauteile des beweglichen Blokkes deformiert werden, um durch die Vorspannung ausgedehnt zu werden, die auf die Kugeln aufgebracht wird, die auf der inneren Oberflächenseite des Flügelbauteiles des beweglichen Blockes angeordnet sind, oder durch eine inverse Radiallast oder eine Querlast, welche auf den beweglichen Block aufgebracht wird, werden die Kontaktwinkel der Kugeln nur geringfügig und wenig verändert, so daß die Richtung der Last, welche auf die Kugeln aufgebracht wird, ungefähr beibehalten wird. Fast keine Änderung der Belastungskapazität der Kugeln, welche durch den Kontaktwinkel der Kugeln bestimmt wird, und ein gleichmäßiges Laufen der Kugeln kann beibehalten werden. Spezieller gesagt, das Deformieren der Flügelbauteile des beweglichen Blokkes, die durch das Aufbringen der inversen Radiallast verursacht wird, kann durch eine geringfügige Bewegung Kontaktpunkte der Kugeln gegenüber der Kugellaufnut und der Kugellaufgegennut absorbiert werden (d. h., eine geringfügige Änderung des Kontaktwinkels der Kugeln) und eine solche Deformation übt keinen Einfluß auf die Belastungskapazität der Kugeln und ihren gleichmäßigen Lauf aus.

Im allgemeinen weist die Kugel eine Belastungskapazität auf, die kleiner ist als die der Rollen. Die inverse Radiallast kann von den vier Reihen von Kugeln aufgenommen werden, die aus zwei Reihen von Kugeln, die auf einer Seitenoberfläche der Führungsschiene angeordnet sind, und die anderen beiden Reihen von Kugeln bestehen, die auf der anderen Seite angeordnet sind. Die vier Reihen von Kugeln weisen gleiche Belastungskapazität wie die beiden Reihen von Rollen auf, die die Radiallast tragen. Zudem kann die Querlast von den beiden Reihen von Kugeln aufgenommen werden, die eine hohe Festigkeit haben, die jedoch nicht so groß ist wie die Belastungskapazität gegen die inverse Radiallast. Solche Reihen von Kugeln können gleichmäßig schwere Lasten in vier Richtungen tragen, d. h., die radiale Richtung, die inverse Radialrichtung und die rechten und linken Querrichtungen.

Insbesondere, wenn die Belastungskapazität der Radialrichtung der Rollen derart vorbestimmt ist, um zwei- bis dreimal so groß zu sein wie die Belastungskapazität in inverser Radialrichtung der Kugeln, kann die Belastungskapazität für die inverse Radiallast, welche durch die vier Reihen von Kugeln erhalten wird, derart eingestellt werden, um im wesentlichen gleich der Belastungskapazität für die Radiallast zu sein, welche durch die beiden Reihen von Rollen erhalten wird. Wo die Belastungskapazität für die Querlast, welche nur durch die beiden Reihen von Kugeln aufgenommen wird, auf im wesentlichen die Hälfte der inversen Radiallast begrenzt ist, kann eine Struktur bereitgestellt werden, in welcher die Lasten in die vier Richtungen, d. h. die radiale Richtung, die inverse radiale Richtung, und die rechten und linken Querrichtungen, ungefähr gleich zueinander gehalten werden können. Der Linearführungsapparat hat daher exzellente Haltbarkeitseigenschaften gegen Lasten in jegliche Richtungen, und kann unter jeglichen Bedingungen verwendet werden, um für verschiedene Zwecke eingesetzt zu werden. Wenn der Linearführungsapparat als ein Tischführungsapparat für eine Werkzeugmaschine verwendet wird, ist es möglich, eine einfache Berechnung für Festigkeit und Lebensdauer durchzuführen, die nützlich für das Bestimmen der mechanischen Struktur ist.

Wenn jede der Kugellaufnuten und der Kugellaufgegennuten einen Krümmungsradius aufweist, der geringer ist als der Wert von 52% des Durchmessers der Kugeln, kann Differenzialschlupf leicht auftreten, wodurch die Dämpfungskapazität verbessert wird.

Die Kraft, die die Funktion des Ausdehnens des Flügelbauteiles des beweglichen Blockes aufweist, wie z. B. die Vorspannung, die auf die Kugeln aufgebracht wird, die inverse Radiallast oder die Querlast, welche auf den beweglichen Block aufgebracht wird, verursacht das simultane Erzeugen des Zugmomentes des mittigen Abschnittes des horizontalen Bauteiles des beweglichen Blockes weg von einem zuführenden Bauteil, wie z. B. ein Bearbeitungstisch. Ein mittiger Abschnitt des horizontalen Bauteiles ist fest mit dem zu führenden Bauteil verbunden durch Bolzen, und es ist daher möglich, das Deformieren des horizontalen Bauteils zu verhindern, so daß ein guter Zustand beibehalten werden kann, in welchem die Rolle mit einem linearen Abschnitt an ihrem Rand in Kontakt mit der Rollenlaufgegenoberfläche kommt, die auf der unteren Oberfläche des horizontalen Bauteils des beweglichen Blockes ausgebildet ist, wodurch eine gute Festigkeit und eine gleichmäßige Rolleigenschaft der Rolle beibehalten wird.

Patentansprüche

1. Ein Linearführungsapparat mit:
einer Führungsschiene, die mit zwei Rollenlaufoberflächen, die an einer oberen Oberfläche der Führungsschiene ausgebildet sind und mit zwei Kugellaufnuten vorgesehen ist, die auf jeder der Seitenoberflächen der Führungsschiene ausgebildet sind;
einem beweglichen Block, der mit einem horizontalen Bauteil versehen ist, welches der oberen Oberfläche der Führungsschiene gegenüberliegt, und mit einem Paar von Flügelbauteilen, die jeweils den Seitenoberflächen der Führungsschiene gegenüberliegen, wobei das horizontale Bauteil auf seiner unteren Oberfläche zwei Rollenlaufgegenoberflächen entsprechend den beiden Rollenlaufoberflächen der Führungsschiene aufweist, und jedes der Flügelbauteile auf einer ihrer inneren Oberflächen zwei Kugellaufgegennuten aufweisen, die den beiden Kugellaufnuten der Führungsschiene entsprechen;
zwei Reihen von Rollen, die zwischen den beiden Rollenlaufoberflächen der oberen Oberfläche der Führungsschiene und den beiden Rollenlaufgegenoberflächen des horizontalen Bauteiles des bewegten Blockes jeweils gegenüberliegen, um rollbar zu sein;
zwei Reihen von Kugeln, die zwischen den beiden Kugellaufnuten der Seitenoberflächen der Führungsschiene und den beiden Kugellaufgegennuten auf den inneren Oberflächen des Flügelbauteiles angeordnet sind, in jeder der Lücken zwischen den Seitenoberflächen der Führungsschiene und den inneren Oberflächen der Flügelbauteile, um rollbar zu sein.
2. Ein Apparat nach Anspruch 1, bei dem:
jede der Kugeln an zwei einander gegenüberliegenden Punkten jeweils mit der Kugellaufnut der Führungsschiene und der Kugellaufgegennut des beweglichen Blockes in Kontakt gelangen, und wobei eine Kontaktlinie, die die beiden einander gegenüberliegenden Punkte miteinander verbindet, nach oben in Richtung zur Führungsschiene geneigt ist.
3. Ein Apparat nach Anspruch 2, bei dem:
Kontaktwinkellinie eine horizontale Linie schneidet, die sich durch eine Mitte der Kugel mit einem Winkel von 45 Grad hindurch erstreckt.
4. Ein Apparat nach einem der Ansprüche 1 bis 3, bei dem:
das horizontale Bauteil des beweglichen Blockes Bolzenlöcher aufweist, welche jeweils zwischen den beiden Reihen von Rollen und außerhalb der beiden Reihen von Rollen angeordnet sind.
5. Ein Apparat nach einem der Ansprüche 1 bis 4, bei dem:
jede der Kugellaufnuten und der Kugellaufgegennuten einen Krümmungsradius aufweist, der kleiner ist als ein Wert von 52% des Durchmessers der Kugel.

(54) Linearführungsvorrichtung

(57) Die Erfindung stellt eine Linearführungsvorrichtung bereit, mit der es möglich ist, Austritt von in ein Gleitstück eingeleitetem Schmiermittel zu verhindern und dadurch eine Schmiermittelverbrauchsmenge zu reduzieren sowie Wälzelemente und einen endlosen Umlaufgang für sie sicher zu schmieren, und mit der dies zudem durch einen einfachen Aufbau erreicht werden kann. Erfindungsgemäß ist bei einer Linearführungsvorrichtung aus einer Spurschiene mit einer Wälzfläche aus Wälzelementen und einem Gleitstück, das eine zur Wälzfläche der Spurschiene weisende Lastwälzfläche mit den Wälzelementen dazwischen und einen Wälzelementrücklaufgang hat, der parallel zu dieser Lastwälzfläche ist, sowie bogenförmige Richtungsumkehrgänge zum Führen von Wälzelementen zwischen der Lastwälzfläche und dem Wälzelementrücklaufgang hat und sich entlang der Spurschiene bei endlosem Umlauf der Wälzelemente bewegen kann, ein Schmiermittelzufuhrloch in Verbindung mit einem der Richtungsumkehrgänge in einer Vorder- und/oder Rükkendfläche des Gleitstücks vorgesehen, die Endfläche, in der dieses Schmiermittelzufuhrloch vorgesehen ist, ist mit einem plattenartigen Teil abgedeckt, eine Schmiermittelzufuhrrinne in Verbindung mit dem Schmiermittelzufuhrloch ist in dieser Endfläche und/oder der Innenfläche des diese Endfläche abdeckenden plattenartigen Teils gebildet, und ein Schmiermittelzufuhrgang ist durch das am Gleitstück befestigte plattenartige Teil gebildet.

DE 198 28 587 A 1

Beschreibung

Die Erfindung betrifft eine Linearführungsvorrichtung, bei der sich ein Gleitstück, das einen bewegbaren Körper, z. B. einen Tisch, stützt, entlang einer Spurschiene auf Roll- oder Wälzelementen, z. B. Kugeln oder Rollen, die durch das Gleitstück umlaufen, bewegt, und insbesondere eine Aufbauverbesserung zum sicheren Zuführen von Schmiermittel zu den Rollelementen.

Zu bekannten Linearführungsvorrichtungen dieser Art gehören jene, die aus einer Spurschiene, die darauf gebildete Rollflächen hat und an einem feststehenden Teil, z. B. einem Bett, angeordnet ist, und aus einem Gleitstück bestehen, das auf dieser Spurschiene mit mehreren Kugeln dazwischen angeordnet ist und sich entlang der Spurschiene bewegt, während es einen bewegbaren Körper, z. B. einen Tisch, stützt.

Das Gleitstück besteht aus einem beweglichen Block und einem Paar Abdeckteilen. Der bewegliche Block hat Lastrollflächen, die zu den Rollflächen der Spurschiene mit Kugeln dazwischen weisen, und Kugelrücklaufgänge, die parallel zu diesen Lastrollflächen sind, und kann sich entlang der Spurschiene auf den Kugeln bewegen. Die Abdeckteile haben bogenförmige Richtungsumkehrgänge zum Führen der Kugeln zwischen den Lastrollflächen und den Kugelrücklaufgängen des beweglichen Blocks. Indem die Abdeckteile an der Vorder- und Rückendfläche des beweglichen Blocks befestigt sind, sind die Enden der Lastrollflächen und der Kugelrücklaufgänge verbunden, und endlose Kugelumlaufgänge sind im Gleitstück vervollständigt.

Um ferner zu verhindern, daß an der Spurschiene haftender Staub u.ä. in das Innere des Gleitstücks bei Bewegung des Gleitstücks eintritt, sind normalerweise plattenartige Abdichtungsteile aus einem weichen elastischen Material, z. B. Gummi, an diesen Vorder- und Rückendflächen befestigt, und das Gleitstück bewegt sich mit diesen Abdichtungsteilen in eng anliegender Berührung mit der Oberfläche der Spur.

Beim Einsatz dieser Linearführungsvorrichtung muß zwecks Unterdrückung von Verschleiß der Kugeln selbst sowie Verschleiß der Rollflächen der Spurschiene und der Lastrollflächen des Gleitstücks, auf denen sie rollen und dadurch eine sehr genaue Bewegung des Gleitstücks lange Zeit beibehalten, ein Schmiermittel, z. B. Schmierfett, diesen Kugeln und den Lastrollflächen periodisch oder kontinuierlich zugeführt werden.

Dazu ist in der zuvor beschriebenen Linearführungsvorrichtung der verwandten Technik ein als Schmiermittelzufuhrgang vorgesehener Kanal in der Rückfläche eines Abdeckteils des Gleitstücks gebildet, d. h., der an den beweglichen Block anstoßenden Fläche, und ein Schmiermittelzufuhrgang in Verbindung mit dem endlosen Kugelumlaufgang von außerhalb des Gleitstücks ist vervollständigt, wenn das Abdeckteil am beweglichen Block befestigt ist.

Da aber dieses Abdeckteil durch Spritzgießen eines relativ harten Kunstharzes hergestellt ist und sich bei selbst geringer Verzerrung im geformten Abdeckteil ein Spalt zwischen dem Abdeckteil und der Endfläche des beweglichen Blocks bildet, an dem es befestigt ist, bestand das Problem, daß in das Gleitstück eingeleitetes Schmiermittel zwischen dem Abdeckteil und dem beweglichen Block austritt und nicht ausreichend Schmiermittel im gesamten endlosen Kugelumlaufgang verteilt werden kann.

Da eingeleitetes Schmiermittel auf diese Weise austritt, bestand zudem das Problem, daß entsprechend mehr Schmiermittel eingeleitet werden muß, damit es die Kugeln und die Lastrollfläche ausreichend schmieren kann, wodurch Schmiermittel vergeudet wird.

Problematisch war außerdem, daß bei Schmierfettzufuhr in den Schmiermittelzufuhrgang mit vorbestimmtem Druck unter Verwendung einer Schmierpresse o. ä. im Fall eines Spalts, der sich zwischen dem Abdeckteil und dem beweglichen Block gebildet hat, der Fülldruck des Schmierfetts durch diesen Spalt nach außen austritt, weshalb Schmierfett nicht ausreichend bis zum Ende des Schmiermittelzufuhrgangs, d. h. zum endlosen Kugelumlaufgang, geführt werden kann.

Eine Linearführungsvorrichtung, bei der versucht wurde, diese Art von Schmiermittelaustritt zu verhindern, ist in der japanischen ungeprüften Gebrauchsmusterveröffentlichung Nr. H.5-71442 offenbart. Insbesondere ist ein Schmiermittelzufuhrloch in einem Abdeckteil mit einem Kugelrichtungsumkehrgang gebildet, und Schmiermittel wird direkt in den Kugelrichtungsumkehrgang durch dieses Zufuhrloch aus einem Schmiermittelzufuhrrohr eingeleitet, das an der Außenfläche des Abdeckteils vorgesehen ist.

Obwohl bei Einsatz dieses Aufbaus der Schmiermittelaustritt zwischen dem beweglichen Block und dem Abdeckteil verhindert werden kann, wird aber ein Rohr an der Außenfläche des Abdeckteils zum Einleiten von Schmiermittel in den Richtungsumkehrgang notwendig, und außerdem wird unter Berücksichtigung der Anordnung des Abdichtungsteils an der Außenfläche des Abdeckteils eine Aussparung in der Außenfläche des Abdeckteils zum Aufnehmen dieses Rohrs ebenfalls notwendig, weshalb das Problem bestand, daß die Anzahl von Teilen steigt und die Struktur des Abdeckteils komplizierter wird.

Daher besteht eine Aufgabe der Erfindung darin, eine Linearführungsvorrichtung bereitzustellen, mit der es möglich ist, den Austritt von in ein Gleitstück eingeleitetem Schmiermittel zu verhindern und dadurch die Schmiermittelverbrauchsmenge zu reduzieren sowie ferner Rollelemente und einen endlosen Rollelementumlaufgang sicher zu schmieren, und mit der sich dies mit einem einfachen Aufbau erreichen läßt. Diese Aufgabe wird mit den Merkmalen der Ansprüche gelöst.

Ist erfindungsgemäß das plattenartige Teil an der Endfläche des Gleitstücks befestigt, ist die in der Endfläche des Gleitstücks oder in der Innenfläche des plattenartigen Teils gebildete Zufuhrrinne abgedeckt, und ein Schmiermittelzufuhrgang ist durch das Gleitstück und das plattenartige Teil vervollständigt. Dann kann Schmiermittel dem Rollelementrichtungsumkehrgang durch diesen Schmiermittelzufuhrgang und das in der Endfläche des Gleitstücks gebildete Schmiermittelzufuhrloch zugeführt werden.

Ist hierbei ein Teil des an das Gleitstück anstoßenden plattenartigen Teils aus einem viskoelastischen Material hergestellt, stellt das am Gleitstück dicht befestigte plattenartige Teil eine eng anliegende Berührung mit der Endfläche des Gleitstücks her, und es bilden sich keine Spalte zwischen dem Plattenartigen Teil und dem Gleitstück. Dadurch läßt sich wirksam verhindern, daß Schmiermittel aus dem durch das Gleitstück und das plattenartige Teil vervollständigten Schmiermittelzufuhrgang austritt, und die Rollelemente sowie ihr endloser Umlaufgang lassen sich mit geringem Schmiermittelverbrauch sicher schmieren.

Da auf diese Weise wirksam verhindert werden kann, daß Schmiermittel aus dem Schmiermittelzufuhrgang austritt, kann auch beim Einspritzen von Schmierfett in den Schmiermittelzufuhrgang unter Verwendung einer Schmierpresse o.a. aufgrund der Tatsache, daß der Fülldruck bei diesem Einspritzen vollständig über dem gesamten Weg bis zum Ende des Schmiermittelzufuhrgangs wirkt, Schmierfett sicher in den Rollelementrichtungsumkehrgang des Gleitstücks eingeleitet werden.

Da bei einer erfindungsgemäßen Linearführungsvorrichtung ein Schmiermittelzufuhrgang durch das Gleitstück und das plattenartige Teil gebildet ist, die dicht aneinanderstoßen, kann somit sicher verhindert werden, daß Schmiermittel zwischen dem Gleitstück und dem plattenartigen Teil austritt, die Schmiermittelverbrauchsmenge läßt sich reduzieren, und die Rollelemente sowie der endlose Umlaufgang können sicher geschmiert werden.

Da ferner bei einem auch als plattenartiges Teil dienenden Abdichtungsteil das Abdichtungsteil selbst ein in Linearführungsvorrichtungen der verwandten Technik verwendeter konstituierender Bestandteil ist, kommt es bei Ausbilden des Schmiermittelzufuhrgangs durch das Gleitstück und das Abdichtungsteil zu keinerlei zusätzlichen Sonderteilen, und der Schmiermittelzufuhrgang kann dadurch mit einem einfachen Aufbau realisiert sein.

Hierbei ist zwecks noch sicherer Verhinderung des Schmiermittelaustritts aus dem Schmiermittelzufuhrgang vorzugsweise ein streifenförmiger Vorsprung, der an die Endfläche des Gleitstücks anstößt, am plattenartigen Teil um den gesamten Umfangsweg der Schmiermittelzufuhrrinne gebildet, die in der Endfläche des Gleitstücks und/oder der Innenfläche des die Endfläche abdeckenden plattenartigen Teils gebildet ist. Geschieht dies, stellt bei Befestigung des plattenartigen Teils am Gleitstück der streifenartige Vorsprung eine noch dichtere eng anliegende Berührung mit der Endfläche des Gleitstücks her, und der Schmiermittelzufuhrgang kann noch vollständiger ausgebildet sein. Ist das plattenartige Teil durch Vulkanisationsformen von Gummi hergestellt, läßt sich zudem der streifenartige Vorsprung leicht in einem Stück mit dem plattenartigen Teil formen.

Zwecks Zufuhr der minimalen notwendigen Schmiermittelmenge zu den im Gleitstück endlos umlaufenden Rollelementen ist vorzugsweise ein Halte- und Zufuhrmaterial zum Halten von Schmiermittel und seinem allmählichen Zuführen zu den Rollelementen im Richtungsumkehrgang in das Schmiermittelzufuhrloch und die Schmiermittelzufuhrrinne gestopft. Beispielsweise kann Harz, Gummi oder Filz für dieses Halte- und Zufuhrmaterial verwendet werden. In diesem Fall fließt überschüssiges Schmiermittel nicht in den Richtungsumkehrgang aus, und nur eine als Ergebnis des Umlaufs der Rollelemente verbrauchte Schmiermittelmenge fließt durch das Halte- und Zufuhrmaterial aus der Schmiermittelzufuhrrinne zum Schmiermittelzufuhrloch, weshalb sich das Gleitstück lange Zeit mit einer extrem kleinen Schmiermittelmenge betreiben läßt. Wird die als Schmiermittelzufuhrgang vorgesehene Schmiermittelzufuhrrinne auf der Gleitstückseite gebildet und etwas groß gestaltet, läßt sich die Schmiermittelmenge, mit der das Halte- und Zufuhrmaterial getränkt werden kann, groß einstellen, wodurch die Häufigkeit reduziert werden kann, mit der die Arbeiten zum Einleiten von Schmiermittel in das Gleitstück durchgeführt werden müssen.

Da in einem Halte- und Zufuhrmaterial, z. B. Filz, gehaltenes Schmiermittel als Ergebnis von Kapillarwirkung gegen die Schwerkraft fließen kann, läßt sich bei Stopfen dieses Halte- und Zufuhrmaterials in die Schmiermittelzufuhrrinne und das Schmiermittelzufuhrloch Schmiermittel auch einem Richtungsumkehrgang sicher zuführen, zu dem eine Schmiermittelzufuhr infolge eines Einflusses der Arbeitshöhe des Gleitstücks relativ schwierig ist.

Zu den "Rollelementen" in der Erfindung gehören Kugeln und Rollen, und die Erfindung kann wirksam die zuvor beschriebenen Effekte in einer Linearführungsvorrichtung bereitstellen, in der entweder Kugeln oder Rollen zum Einsatz kommen.

Im folgenden wird eine Linearführungsvorrichtung anhand der beigefügten Zeichnungen näher beschrieben.

Fig. 1 und **Fig.** 2 zeigen eine erste bevorzugte Ausführungsform einer erfindungsgemäßen Linearführungsvorrichtung. In diesen Darstellungen hat eine Spurschiene **1** Führungsfedern **11**, die in Axialrichtung in ihrem linken und rechten Schulterteil vorgesehen sind. Kugelrollflächen **12**, auf denen Kugeln **2** rollen, sind in einem oberen und unteren Teil jeder der Führungsfedern **11** gebildet, und jede der Kugelrollflächen **12** bildet einen Winkel von 45° zu einer Querrichtung und einer Schubrichtung. Diese Spurschiene **1** ist durch (nicht gezeigte) Befestigungsbolzen an einem feststehenden Teil, z. B. einem (nicht gezeigten) Bett, befestigt. In **Fig.** 1 bezeichnet die Bezugszahl **13** Bolzenlöcher, durch die diese Befestigungsbolzen geführt werden.

Die Bezugszahl **3** bezeichnet ein Gleitstück, das sich entlang der Spurschiene **1** bewegt und aus einem beweglichen Block **4**, der zusammen mit der Spurschiene **1** die Kugeln **2** dazwischen aufnimmt, einem Paar Abdeckteilen **5**, die an einer Vorder- und Rückendfläche dieses beweglichen Blocks befestigt sind, und einem Paar Abdichtungsteilen (plattenartigen Teilen) **6**, die an den Außenflächen dieser Abdeckteile **5** befestigt sind, hergestellt ist.

Gemäß **Fig.** 2 ist der bewegliche Block **4** in Form eines Sattels ausgebildet, der die Spurschiene **1** überspannt und ein waagerechtes Teil **4**a sowie ein Paar Hülsenteile **4**b hat, die von den Seiten dieses waagerechten Teils **4**a herabhängen, und vier Lastrollflächen **41**, die zusammen mit den Kugelrollflächen **12** der Spurschiene **1** die Kugeln **2** dazwischen aufnehmen, sind auf den Innenflächen dieser Hülsenteile **4**b gebildet. Außerdem durchlaufen Kugelrücklaufgänge **42**, die den Lastrollflächen **41** entsprechen und parallel dazu sind, die Hülsenteile **4**b. Anordnungsteile **44** mit Bolzenlöchern **43** sind von den Seitenflächen des beweglichen Blocks **4** vorspringend vorgesehen, und der bewegliche Block **4** ist an einem bewegbaren Körper, z. B. einem (nicht gezeigten) Tisch, durch (nicht gezeigte) Befestigungsbolzen befestigt, die durch die vorgenannten Bolzenlöcher **43** von unterhalb dieser Anordnungsteile **44** verlaufen.

Kugelhalteplatten **45**, **46** sind an den unteren Enden der Hülsenteile **4**b des beweglichen Blocks **4** bzw. an der Unterseite des waagerechten Teils **4**a befestigt. Hergestellt sind diese Kugelhalteplatten **45**, **46** z. B. durch Preßformen von Blech oder Spritzgießen eines harten Kunstharzes, und sie verhindern, daß die auf den Lastrollflächen **41** rollenden Kugeln **2** herausfallen, wenn das Gleitstück **3** von der Spurschiene **1** entfernt wird.

Fig. 3 ist eine Perspektivansicht eines der Abdeckteile **5** im Blick von der Rückflächenseite. Jedes der Abdeckteile **5** ist in Form eines Sattels mit einem waagerechten Teil **5**a und einem Paar Hülsenteile **5**b ausgebildet, die von den Seiten dieses waagerechten Teils **5**a wie beim beweglichen Block **4** herabhängen, und Kugelrichtungsumkehrgänge **51**, die einzeln die Lastrollflächen **41** und die Kugelrücklaufgänge **42** der Blockseite verbinden, sind in den Rückflächenseiten der Hülsenteile **5**b vorgesehen.

In **Fig.** 4 ist einer dieser Kugelrichtungsumkehrgänge **51** näher dargestellt. Eine im wesentlichen halbkreisförmige Außenführungsfläche **52** ist im Abdeckteil **5** gebildet und führt die Kugeln **2** in einem Kreisbogen zwischen der Kugelrollfläche **12** der Spurschiene **1** und dem Kugelrücklaufgang **42**. Ein Schaufelteil **53** zum Hochschaufeln der Kugeln **2** von der Kugelrollfläche **12** der Spurschiene **1** ist am Ende dieser Außenführungsfläche **52** gebildet. Ein Kugelführungsteil **7** paßt sich gegenüber dieser Außenführungsfläche **52** ein, und eine Innenführungsfläche **71** zum Führen der Kugeln **2** zwischen dem Kugelrücklaufgang **42** und der Lastrollfläche **41** ist auf diesem Kugelführungsteil **7** gebildet. Das heißt, durch das Einpassen des Kugelführungsteils **7** in das Abdeckteil **5** gemäß **Fig.** 4 liegen die Außenführungsfläche **52** und die Innenführungsfläche **71** einander gegenüber, und ein Kugelrichtungsumkehrgang **51** ist vervollständigt.

Schmiermittelzufuhrlöcher **56** sind einzeln vorgesehen und erstrecken sich zwischen der Außenfläche des Abdeckteils **5**, an dem das Abdichtungsteil **6** befestigt ist, und den Kugelrichtungsumkehrgängen **51**, und ein Schmiermittel, z. B. Schmierfett, kann in die Kugelrichtungsumkehrgänge **51** durch diese Schmiermittelzufuhrlöcher **56** eingeleitet werden, um die durch das Innere der Kugelrichtungsumkehrgänge **51** rollenden Kugeln **2** zu schmieren.

Diese Abdeckteile **5** sind an den Enden des beweglichen Blocks **4** mittels Innensechskantbolzen befestigt, die durch Anordnungslöcher **54** laufen. Vorsprünge **55** zum Positionieren sind von der Rückfläche jedes der Abdeckteile **5** um die Anordnungslöcher **54** vorragend vorgesehen, und durch Einpassen dieser Vorsprünge **55** in (nicht gezeigte) Aussparungen in den Endflächen des beweglichen Blocks **4** sind die Abdeckteile **5** gegenüber dem beweglichen Block **4** genau positioniert. Bei einer solchen Befestigung der Abdeckteile **5** am beweglichen Block **4** sind die Kugelrichtungsumkehrgänge **51** der Abdeckteile **5** und die Kugelrücklaufgänge **42** des beweglichen Blocks **4** verbunden, und endlose Kugelumlaufgänge zum Umwälzen der Kugeln **2** von einem Ende jeder der Lastrollflächen **41** zum anderen sind vervollständigt.

Gemäß **Fig.** 4 und **Fig.** 5 erfolgt die Herstellung jedes der Abdichtungsteile **6** durch Überziehen der Rückflächenseite, d. h. der Seite, die an das jeweilige Abdeckteil **5** anstoßen soll, einer als Kern dienenden Platte **61** mit einem Gummiformteil **62** durch Vulkanisationsformen, und die Gesamtheit ist in Form einer Platte gebildet, die im wesentlichen die gleiche Außenform wie der Querschnitt des Abdeckteils **5** hat. Ein Lippenteil **63**, das eine Gleitberührung mit der Spurschiene **1** herstellt, ist einstückig mit dem Gummiformteil **62** entlang der zur Spurschiene **1** weisenden Seite des Abdichtungsteils **6** gebildet und verhindert, daß Staub, Schmiermittel usw., die an der Spurschiene **1** haften, in das Innere des Gleitstücks **3** bei Bewegung des Gleitstücks **3** eintreten. In **Fig.** 5 bezeichnet die Bezugszahl **64** Schraubenlöcher zum Befestigen des Abdichtungsteils **6** am Abdeckteil **5**.

Ein Schmierspeicher **57** ist in der Endfläche des Abdeckteils **5** gebildet, an dem dieses Abdichtungsteil **6** befestigt ist (siehe **Fig.** 1), und ein (nicht gezeigter) Schmiernippel kann in diesen Schmierspeicher **57** durch eine im Abdichtungsteil **6** gebildete Ölzufuhröffnung **65** eingeschraubt sein.

Eine den Schmierspeicher **57** mit den Schmiermittelzufuhrlöchern **56** verbindende Schmiermittelzufuhrrinne **66** ist im Gummiformteil **62** des an die Endfläche des Abdeckteils **5** anstoßenden Abdichtungsteils **6** gebildet, und durch die Befestigung dieses Abdichtungsteils **6** an der Endfläche des Abdeckteils **5** ist ein Schmiermittelzufuhrgang vervollständigt, der sich vom Schmierspeicher **57** zu den Kugelrichtungsumkehrgängen **51** erstreckt.

Außerdem ist gemäß **Fig.** 6 ein streifenförmiger Vorsprung **67** über den gesamten Weg entlang den Seiten der Schmiermittelzufuhrrinne **66** gebildet, und bei Befestigung des Abdichtungsteils **6** am Abdeckteil **5** stellt der streifenförmige Vorsprung **67** eine dichte, eng anliegende Berührung mit der Endfläche des Abdeckteils **5** her und verhindert sicher, daß Schmiermittel aus dem Inneren der Schmiermittelzufuhrrinne **66** austritt.

Wird bei einer Linearführungsvorrichtung dieser bevorzugten Ausführungsform mit dem zuvor beschriebenen Aufbau Schmierfett aus einem am Abdeckteil **5** befestigten Schmiernippel unter Verwendung einer Schmierpresse eingespritzt, tritt es in die Schmiermittelzufuhrrinne **66** des Abdichtungsteils **6** über den in der Endfläche des Abdeckteils **5** gebildeten Schmierspeicher **57** ein, läuft entlang dieser Schmiermittelzufuhrrinne **66** und spritzt durch die Schmiermittelzufuhrlöcher **56** in die Kugelrichtungsumkehrgänge **51** aus. Damit werden die durch diese Kugelrichtungsumkehrgänge **51** rollenden Kugeln **2** durch das Schmierfett geschmiert, und das Schmierfett breitet sich zu den Lastrollflächen **41** und den Kugelrücklaufgängen **42** beim Umlaufen der Kugeln **2** aus.

Da hierbei das Gummiformteil **62** des am Abdeckteil **5** befestigten Abdichtungsteils **6** an die Endfläche des Abdeckteils **5** anstößt und dieses Gummiformteil **62** durch die Platte **61** in eng anliegende Berührung mit dem Abdeckteil **5** gedrückt wird, bilden sich keine Spalte zwischen dem Abdichtungsteil **6** und dem Abdeckteil **5**. Daher tritt kein Schmierfett aus dem Schmierspeicher **57** oder der Schmiermittelzufuhrrinne **66** aus, und das unter Druck mittels Schmierpresse eingeleitete Schmierfett kann in die Richtungsumkehrgänge **51** sicher eingespritzt werden.

Obwohl in der zuvor beschriebenen bevorzugten Ausführungsform Schmierfett unter Verwendung einer Schmierpresse eingeleitet wird, kann alternativ ein Aufbau zum Einsatz kommen, bei dem ein Rohr kontinuierlich mit dem Gleitstück **3** verbunden ist und ein Schmiermittel in Nebelform in die Schmiermittelzufuhrrinne **66** unter Verwendung dieses Rohrs eingeblasen wird.

Obwohl ferner in dieser bevorzugten Ausführungsform ein ursprünglich zur Staubverhinderung vorgesehenes Abdichtungsteil **6** auch als plattenartiges Teil wirkt, das einen Schmiermittelzufuhrgang zwischen sich und dem Gleitstück **3** bildet, um eine Erhöhung der Anzahl von Teilen zu umgehen, die aus der Bereitstellung des plattenartigen Teils resultiert, kann alternativ ein Aufbau zum Einsatz kommen, bei dem z. B. ein plattenartiges Teil aus dem gleichen Material getrennt vom Abdichtungsteil hergestellt und an der Endfläche des Gleitstücks befestigt ist, um einen Schmiermittelzufuhrgang zu bilden.

Als nächstes wird eine zweite bevorzugte Ausführungsform einer erfindungsgemäßen Linearführungsvorrichtung beschrieben.

Während in der zuvor beschriebenen ersten bevorzugten Ausführungsform die Schmiermittelzufuhrrinne **66** in dem am Abdeckteil **5** befestigten Abdichtungsteil **6** gebildet war, ist in dieser zweiten bevorzugten Ausführungsform die

Schmiermittelzufuhrrinne **66** auf der Seite des Abdeckteils **5** gebildet, und ein Halte- und Zufuhrmaterial ist in diese Schmiermittelzufuhrrinne gestopft.

Fig. 7 ist eine Perspektivansicht eines Abdeckteils **5** dieser bevorzugten Ausführungsform im Blick von seiner Seite, an der ein Abdichtungsteil **6** zu befestigten ist. In dieser Seite des Abdeckteils **5** ist eine Aussparung **58** zum Halten von Schmiermittel im waagerechten Teil **5**a des Abdeckteils **5** gebildet, und Schmiermittelzufuhrrinnen **59** in Verbindung mit dieser Aussparung **58** sind in den Hülsenteilen **5**b gebildet. Außerdem sind wie bei der Beschreibung der ersten bevorzugten Ausführungsform Schmiermittelzufuhrlöcher **56** in Verbindung mit Kugelrichtungsumkehrgängen **51** in diesem Abdeckteil **5** vorgesehen, und die Schmiermittelzufuhrrinnen **59** sind ebenfalls mit diesen Schmiermittelzufuhrlöchern **56** verbunden. Mit einem Schmiermittel getränkter Filz **60** ist in die Aussparung **58**, die Schmiermittelzufuhrrinnen **59** und die Schmiermittelzufuhrlöcher **56** gestopft.

Fig. 8 ist eine Schnittansicht dieses Abdeckteils **5** der zweiten bevorzugten Ausführungsform, das am zuvor beschriebenen beweglichen Block **4** mit einem Abdichtungsteil **6** befestigt ist, das am Abdeckteil **5** befestigt ist. Bei Befestigung dieses Abdeckteils **5** am beweglichen Block **4** gemäß der vorstehenden Beschreibung ist jeder der Kugelrichtungsumkehrgänge **51** des Abdeckteils **5** mit einem Kugelrücklaufgang **42** des beweglichen Blocks **4** verbunden und komplettiert einen endlosen Umlaufgang für umlaufende Kugeln **2** von einem Ende einer Lastrollfläche **41** zum anderen, wobei Spitzen des in die Schmiermittelzufuhrlöcher **56** gestopften Filzes **60** etwas in die Kugelrichtungsumkehrgänge **51** vorragen.

Der übrige Aufbau des Abdeckteils **5**, d. h. die Spurschiene **1**, der bewegliche Block **4** usw., entspricht exakt dem der zuvor beschriebenen ersten bevorzugten Ausführungsform und wird daher hier nicht beschrieben.

Bei Befestigung des Abdichtungsteils **6** am Abdeckteil **5** sind auch bei der Linearführungsvorrichtung dieser bevorzugten Ausführungsform die im Abdeckteil **5** gebildete Aussparung **58** und die Schmiermittelzufuhrrinne **59** durch das Abdichtungsteil **6** abgedeckt, und ein Schmiermittelzufuhrgang, der sich von der Aussparung **58** zu den Kugelrichtungsumkehrgängen **51** erstreckt, ist vervollständigt. Da hierbei das Gummiformteil **62** des Abdichtungsteils **6** dicht an das Abdeckteil **5** anstößt und kein Spalt zwischen beiden gebildet ist, ist auch in dieser bevorzugten Ausführungsform der Schmiermittelaustritt aus der Aussparung **58** oder der Schmiermittelzufuhrrinne **59** sicher verhindert.

Da ferner in dieser bevorzugten Ausführungsform Filz **60** in die Aussparung **58**, die Schmiermittelzufuhrrinnen **59** und die Schmiermittelzufuhrlöcher **56** gestopft ist, wird in die Aussparung **58** durch die Ölzufuhröffnung **65** im Abdichtungsteil **6** eingespritztes Schmiermittel vom Filz **60** aufgenommen und gehalten und durchläuft diesen Filz **60** zu den Kugelrichtungsumkehrgängen **51**. Da Schmiermittel direkt auf die Kugeln **2** aus dem etwas in die Kugelrichtungsumkehrgänge **51** vorragenden Filz **60** aufgetragen wird, fließt somit Schmiermittel nicht umsonst in die Kugelrichtungsumkehrgänge **51**, und die Kugeln **2** können mit der minimalen notwendigen Schmiermittelmenge sicher geschmiert werden.

Da zudem in dieser bevorzugten Ausführungsform die Aussparung **58** etwas größer als die Schmiermittelzufuhrrinnen **59** ausgebildet ist, so daß eine wesentliche Schmiermittelmenge im Filz **60** innerhalb dieser Aussparung **58** gehalten werden kann, wird durch die Ölzufuhröffnung **65** des Abdichtungsteils **6** eingespritztes Schmiermittel nicht schnell verbraucht, wodurch die Häufigkeit reduziert werden kann, mit der die Arbeiten zur erneuten Schmiermittelzufuhr zum Gleitstück durchzuführen sind, während die Linearführungsvorrichtung in Gebrauch ist.

Patentansprüche

1. Linearführungsvorrichtung mit: einer Spurschiene mit einer Wälzfläche aus Wälzelementen und einem Gleitstück, das eine zur Wälzfläche der Spurschiene weisende Lastwälzfläche mit den Wälzelementen dazwischen sowie einen Wälzelementrücklaufgang hat, der parallel zu dieser Lastwälzfläche ist, und bogenförmige Richtungsumkehrgänge zum Führen der Wälzelemente zwischen der Lastwälzfläche und dem Wälzelementrücklaufgang hat und sich entlang der Spurschiene bewegen kann, wobei die Wälzelemente endlos umlaufen,
wobei ein Schmiermittelzufuhrloch in Verbindung mit einem der Richtungsumkehrgänge in einer Vorder- und/oder Rückendfläche des Gleitstücks vorgesehen und die Endfläche, in der das Schmiermittelzufuhrloch vorgesehen ist, mit einem plattenartigen Teil abgedeckt ist, und eine Schmiermittelzufuhrrinne in Verbindung mit dem Schmiermittelzufuhrloch in dieser Endfläche und/oder der Innenfläche des diese Endfläche abdekkenden plattenartigen Teils vorgesehen und ein Schmiermittelzufuhrgang durch das am Gleitstück befestigte plattenartige Teil gebildet ist.
2. Vorrichtung nach Anspruch 1, wobei mindestens ein Teil des eine Berührung mit der Endfläche des Gleitstücks herstellenden plattenartigen Teils aus einem viskoelastischen Material besteht.
3. Vorrichtung nach Anspruch 1 oder 2, wobei das plattenartige Teil ein Abdichtungsteil ist, das eine Gleitberührung mit der Spurschiene herstellt.
4. Vorrichtung nach Anspruch 1, 2 oder 3, wobei ein streifenförmiger Vorsprung, der an die Endfläche des Gleitstücks anstößt, über den gesamten Umfangsweg der Schmiermittelzufuhrrinne gebildet ist.
5. Vorrichtung nach einem der Ansprüche 1 bis 4, wobei ein Halte- und Zufuhrmaterial zum Halten von Schmiermittel und zu seinem allmählichen Zuführen zu den Wälzelementen innerhalb des Richtungsumkehrgangs in das Schmiermittelzufuhrloch und die Schmiermittelzufuhrrinne gestopft ist.

Beschreibung

HINTERGRUND DER ERFINDUNG

Gebiet der Erfindung

Die vorliegende Erfindung bezieht sich auf eine Führungsvorrichtung für eine geradlinige Bewegung, bei der ein einen Durchlaß ausbildendes Teil, das aus Harz ausgeformt ist, in einen Körper eines beweglichen Teils eingebaut ist.

Beschreibung der verwandten Technik

Der Anmelder hat bereits eine technische Erfindung vorgeschlagen, daß bei einem beweglichen Block einer Führungsvorrichtung für eine geradlinige Bewegung ein Paar von Abschnitten, die einen Kugeldurchlaß bilden und sich entlang den gegenüberliegenden, in Längsrichtung verlaufenden Seiten einer Tragkugellaufnut erstrecken, ein Abschnitt, der einen Kugelrücklauf ausbildet, und ein Paar von Abschnitten, die eine innere Führung und einen Richtungswechseldurchlaß bilden, einstückig in einem Körper des beweglichen Blocks aus Harz gefertigt sind (vgl. vorläufige japanische Patentveröffentlichung Nr. H7-317 762).

Wenn insbesondere die Formgebung aus Harz durchgeführt wird, wird der Körper des beweglichen Blockes in eine Form eingesetzt und die den Kugeldurchlaß bildenden Abschnitte, die einen Richtungswechseldurchlaß und innere Führung bildenden Abschnitte oder der den Ballrücklauf bildende Abschnitt sind im Blockkörper einstückig ausgebildet.

Bei dem herkömmlichen, beweglichen Block, der durch eine einstückige Ausbildung erhalten wird, wird der Blockkörper wie oben erwähnt in die Form eingesetzt. Wenn der Blockkörper groß ist, muß eine entsprechend große Form verwendet werden. Es ist zum einen nicht einfach, eine derartige große Form vorzubereiten und zum anderen gibt es hinsichtlich der Größe tatsächlich eine Beschränkung. Die den Kugeldurchlaß bildenden Abschnitte, die an den gegenüberliegenden, in Längsrichtung verlaufenden Seiten der Kugellaufnut angeordnet sind und sich in Längsrichtung des Blockkörpers erstrecken, sind schmal und lang, was zur Folge hat, daß flüssiges Harz nicht jeden Raumabschnitt zur Ausbildung der den Kugeldurchlaß bildenden Abschnitte während der Formgebung mit Harz erreichen kann.

Eine Erhöhung der Anzahl von Eingußstellen, die in der Form ausgebildet sind, kann das oben erwähnte Problem einer vom flüssigen Harz mangelhaft ausgefüllten Form lösen. Wenn jedoch der Blockkörper in die Form eingesetzt wird, kann der Blockkörper dem Lauf des flüssigen Harzes verschlechtern.

Wenn der bewegliche Block ein Paar von Schenkelabschnitten aufweist, die rechten und linken Seitenabschnitten der Führungsschiene gegenüberliegen, so daß die Führungsschiene zwischen den Schenkelabschnitten gehalten ist, und vier Kugelzüge zwischen den rechten und linken Seitenabschnitten der Führungsschiene und den rechten und linken Schenkelabschnitten des beweglichen Blockes vorgesehen sind und insbesondere die oberen und unteren Kugellaufbahnen jeweils an einer Lücke zwischen dem rechten Seitenabschnitt des Führungsabschnittes und dem entsprechenden rechten Schenkelabschnitt des beweglichen Blockes und an einer weiteren Lücke zwischen dem linken Seitenabschnitt der Führungsschiene und dem entsprechenden linken Schenkelabschnitt des beweglichen Blockes sich befinden, dann kann der in die Form eingesetzte Blockkörper den Lauf des flüssigen Harz in Breitenrichtung des beweglichen Blockes verschlechtern.

ZUSAMMENFASSUNG DER ERFINDUNG

Ein Ziel der vorliegenden Erfindung ist daher, eine Führungsvorrichtung für eine geradlinige Bewegung bereitzustellen, bei der ein aus Harz geformter Körper zur Ausbildung eines Rollkörperumlaufs getrennt von einem Körper eines beweglichen Teils ausgebildet ist, so daß eine leichte Formgebung des aus Harz gebildeten Körpers möglich ist und der derartig aus Harz gebildete Körper in den Körper des beweglichen Teils eingebaut werden kann, wodurch eine einstückige Formbarkeit der größtmöglichen Anzahl von Einheitsstücken zur Bestimmung des Rollkörperumlaufs sichergestellt wird.

Um das obengenannte Ziel zu erreichen, weist eine Führungsvorrichtung für eine geradlinige Bewegung die folgenden Merkmale auf:
ein Führungsteil, das mit einer Rollkörperlaufbahn versehen ist, und
ein bewegliches Teil, das derart angeordnet ist, daß es entlang des Führungsteils über eine große Anzahl von Rollkörpern beweglich ist, wobei das bewegliche Teil versehen ist mit (**1**) einer Rollkörpergegenlaufbahn, die der Rollkörperlaufbahn des Führungsteils entspricht, (ii) einem Rollkörperrücklauf, der in einem vorgegebenen Abstand von der Rollkörpergegenlaufbahn parallel zu dieser angeordnet ist und (iii) einem Paar von Richtungswechseldurchlässen, die die Rollkörpergegenlaufbahn und den Rollkörperrücklauf verbinden, um einen Umlauf der Rollkörper zu ermöglichen,
dadurch gekennzeichnet, daß:
ein aus Harz gebildeter Körper, der einen Rollkörperumlauf bildet, ein Paar von einen Rollkörperdurchlaß bildenden Abschnitten aufweist, die sich entlang der beiden in Längsrichtung verlaufenden Seiten der Rollkörpergegenlaufbahn erstrecken, einen einen Rücklauf bildenden Abschnitt, der einen Rollkörperrücklauf bildet, und ein Paar von einen Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitten, die innere, in Umfangsrichtung verlaufende Führungsabschnitte der Richtungswechseldurchlässe bilden, wobei der aus Harz geformte Körper getrennt vom Körper des beweglichen Teils ausgebildet ist; und
zumindest zwei Abschnitte (a) des Paars der den Rollkörperdurchlaß bildenden Abschnitte (b) des den Rücklauf bildenden Abschnittes, (c) einer des Paars der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte und (d) ein weiteres Paar der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte miteinander einstückig verbunden sind, so daß der aus Harz gebildete Körper in den Körper des beweglichen Teils eingebaut werden kann.

Ausführungsbeispiele der Kombination dieser Abschnitte (a) bis (d) beim aus Harz gebildeten Körper können zur Ausbildung des Rollkörperumlaufs die folgenden drei Beispiele umfassen:
das erste Beispiel, bei dem der aus Harz geformte Körper (i) einen einstückig ausgebildeten Körper aus dem Paar von den den Rollkörperdurchlaß bildenden Abschnitten und dem Paars der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte und (ii) den den Rücklauf bildenden Abschnitt aufweist, die getrennt vom einstückigen Körper ausgebildet sind;
das zweite Beispiel, bei dem der aus Harz gebildete Körper (i) einen einstückig ausgebildeten Körper des Paars von den Rollkörperdurchlaß bildenden Abschnitten, den den Rücklauf ausbildenden Abschnitt und eines Paars der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte, und (ii) ein weiteres Paar der den Richtungswechseldurchlaß und innere Führung ausbildenden Ab-

schnitte aufweist, die getrennt vom einstückigen Körper ausgebildet sind; und

das dritte Beispiel, bei dem der aus Harz gebildete Körper dadurch hergestellt ist, daß ein einstückiger Körper aus dem Paar der den Rollkörperdurchlaß bildenden Abschnitte, dem den Rücklauf ausbildenden Abschnitt und dem Paar der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte vorbereitet wird, und dann das Paar von den Rollkörperdurchlaß ausbildenden Abschnitte und der den Rücklauf ausbildenden Abschnitt jeweils in zwei in Längsrichtung verlaufende, zwischenliegende Abschnitte geteilt ist.

Entsprechend der vorliegenden Erfindung ist der aus Harz gebildete Körper zur Ausbildung des Rollkörperumlaufs getrennt vom Körper des beweglichen Teils ausgebildet. Selbst wenn das bewegliche Teil groß ist, wird dadurch der Fluß des flüssigen Harzes nicht vom Körper des beweglichen Teils behindert wie im Stand der Technik, bei dem der Körper des beweglichen Teils und der aus Harz gebildete Körper einstückig miteinander ausgebildet sind. Dadurch ist es möglich, einen guten Lauf des flüssigen Harz durch eine Erhöhung der Anzahl von Eingußstellen in der Form sicherzustellen, was zu einer hervorragenden Formgebung führt. Im allgemeinen ist ein passender Lauf des flüssigen Harz insbesondere bei den den Rollkörperdurchlaß bildenden Abschnitten, die sich entlang den in Längsrichtung verlaufenden Seiten der Rollkörpergegenlaufbahn erstrecken, schwer zu erreichen und daher ist es von Vorteil, den aus Harz gebildeten Körper getrennt vom Körper des beweglichen Teils gemäß der vorliegenden Erfindung zu formen.

Der Rollkörperumlauf wird durch den aus Harz geformten Körper gebildet. Dadurch kann eine direkte Lagebestimmung in der relativen Lagebeziehung zwischen den den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitten und dem den Rollkörperdurchlaß bildenden Abschnitt sowie der relativen Lagebeziehung zwischen den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten und dem den Rücklauf bildenden Abschnitt erreicht werden und die Durchgängigkeit des Rollkörperumlaufs wird in vorteilhafter Weise sichergestellt und führt so zu einem glatten Lauf der Rollkörper.

Da die den Rollkörperdurchlaß bildenden Abschnitte entlang der beiden sich in Längsrichtung erstreckenden Seiten der Rollkörpergegenlaufbahn angeordnet sind, sind die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte, die in einer geeigneten relativen Lagebeziehung zu den den Rollkörperdurchlaß bildenden Abschnitten stehen, genau an den beiden Enden der Rollkörpergegenlauffläche gesetzt.

Die Beibehaltung einer geeigneten relativen Lagebeziehung der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte zum Rollkörperrücklauf bewirkt, daß die den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte genau mit der inneren Oberfläche des Rollkörperrücklaufs verbunden sind.

Insbesondere findet der Wechsel einer Laufrichtung der Rollkörper in der Verbindungsfläche der den Rollkörperdurchlaß bildenden Abschnitte mit den den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte sowie in der Verbindungsfläche der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte mit dem den Rücklauf ausbildendem Abschnitt statt. Wenn zwei Abschnitte in einer derartigen Verbindungsfläche miteinander durch einstückige Formgebung miteinander verbunden werden, ist ein Schritt zum Zusammenbauen dieser beiden Abschnitte nicht notwendig, wodurch es möglich ist, eine glatte Durchgängigkeit dieser beiden Abschnitte sicherzustellen, die durch die Genauigkeit beim Zusammenbau nicht beeinflußt wird.

Wenn die den Rollkörperdurchlaß bildenden Abschnitte und die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte einstückig miteinander ausgebildet sind, um auf diese Weise die glatte Verbindungsfläche zu bilden, ist es möglich, den glatten Lauf der Rollkörper in der Verbindungsfläche dieser Abschnitte zu erreichen und dadurch die Umlaufeigenschaften der Rollkörper zu verbessern, ohne einen aus Harz gefertigten, einen Rücklauf bildenden Abschnitt vorzusehen. Durch einen derartigen Aufbau ist eine leichte Herstellung der Vorrichtung aufgrund des fehlenden, den Rücklauf bildenden Abschnittes möglich.

Die vorliegende Erfindung kann die zusätzlichen Merkmale aufweisen, daß ein Rollkörperkäfig vorgesehen ist, der in der Lage ist, die Rollkörper in einem vorgegebenen Abstand zwischen zwei benachbarten Rollkörpern zu halten und der Seitenkantenabschnitte aufweist, die von beiden Seiten eines jeden Rollkörpers hervorragen; und Führungsnuten zum Führen der Seitenkantenabschnitte des Rollkörperkäfigs am gesamten Umfang des Rollkörperumlaufs ausgebildet sind.

Die vorliegende Erfindung kann die zusätzlichen Merkmale aufweisen, daß ein Halteabschnitt an dem den Rollkörperdurchlaß bildenden Abschnitt vorgesehen ist, um zu verhindern, daß der Rollkörperkäfig seine Lage verläßt, wenn das bewegliche Teil vom Führungsteil entfernt wird, und ein Führungsabschnitt durchgängig am gesamten Umfang des Rollkörperumlaufs ausgebildet ist, um die Seitenkantenabschnitte des Rollkörperkäfigs zu führen.

Ein derartiger Rollkörperkäfig ermöglicht den glatten Umlauf der Rollkörper aufgrund der Wahrung der Durchgängigkeit des Führungsabschnitts für den Rollkörperkäfig.

Da der Führungsabschnitt für den Rollkörperkäfig, der im übrigen eine kleine Dicke aufweist, nicht durch Einsetzen des Körpers des beweglichen Teils in eine Form und dem darauffolgenden Einspritzen von flüssigen Harz in die Form ausgebildet wird, sondern getrennt vom Körper des beweglichen Teils geformt wird, kann die Lage der Eingußstellen ohne Einschränkung durch den Körper des beweglichen Teils frei bestimmt werden, mit dem Ergebnis, daß das flüssige Harz während des Formens des Führungsabschnittes den gesamten, dafür vorgesehenen Raum ausfüllen kann, der in der Form ausgebildet ist.

Die vorliegende Erfindung kann die zusätzlichen Merkmale aufweisen, daß ein jeder der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte einen dünnen Plattenabschnitt aufweist, der mit der Endfläche des Körpers des beweglichen Teils in Kontakt gebracht wird, wobei ein jeder der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte mit den den Rollkörperdurchlaß bildenden Abschnitten oder dem den Rücklauf ausbildenden Abschnitt mittels dem dünnen Plattenabschnitt verbunden ist.

Wenn ein jeder der den Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitte mit den den Rollkörperdurchlaß bildenden Abschnitte mittels dem dünnen Plattenabschnitt verbunden ist, kann eine Verformung des dünnen Plattenabschnitts eine Verschiebung ausgleichen, die zwischen dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rollkörperdurchlaß bildenden Abschnitt oder zwischen dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rücklauf bildenden Abschnitt auftritt. Dementsprechend ist es möglich, eine genaue Lagebeziehung zwischen dem Ende des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes und dem den Rollkörperdurchlaß bildenden Abschnitt oder zwischen dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rücklauf bildenden Abschnitt beizubehalten.

Der dünne Plattenabschnitt wird durch eine auf die seitliche Deckplatte wirkende Klemmkraft gegen das flache Ende des Körpers des beweglichen Teils gedrückt. Die Lage des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes kann dadurch über eine Verformung des dünnen Plattenabschnittes korrigiert werden, selbst wenn der dem Richtungswechseldurchlaß und innere Führung bildende Abschnitt gegenüber der Endfläche des Körpers des beweglichen Teils falsch positioniert ist. Zusätzlich kann der dünne Plattenabschnitt fest zwischen der seitlichen Deckplatte und dem Körper des beweglichen Teils durch die auf die seitliche Deckplatte wirkende Klemmkraft gesichert werden, wodurch eine falsche Plazierung des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes verhindert wird.

Die Vorrichtung der vorliegenden Erfindung kann derart aufgebaut sein, daß das Führungsteil eine Führungsschiene aufweist, das bewegliche Teil einen beweglichen Block aufweist, der mit einem waagerechten Abschnitt versehen ist, welcher einer oberen Fläche der Führungsschiene und einem Paar von Schenkelabschnitten gegenüberliegt, zwischen denen die Führungsschiene an deren rechten und linken Seitenflächen gehalten ist; zwei Rollkörperlaufbahnen in einer Lücke zwischen der oberen Fläche der Führungsschiene und einer unteren Fläche des beweglichen Blocks angeordnet sind und eine einzelne Rollkörperlaufbahn in einer jeden Lücke zwischen den rechten und linken Seitenflächen der Führungsschiene und den beiden Schenkelabschnitten angeordnet ist, so daß insgesamt vier Bahnen vorhanden sind.

Die Vorrichtung der vorliegenden Erfindung kann derart aufgebaut sein, daß das Führungsteil eine Führungsschiene aufweist, das bewegliche Bauteil einen beweglichen Block aufweist, der mit einem Paar von Schenkelabschnitten versehen ist, zwischen denen die Führungsschiene an deren rechten und linken Seitenflächen gehalten ist; und zwei Rollkörperlaufbahnen in einer jeden Lücke zwischen den rechten und linken Seitenflächen der Führungsschiene und den beiden Schenkelabschnitten angeordnet sind, so daß insgesamt vier Bahnen vorhanden sind.

In diesen Fällen können jeweils vier einen Richtungswechseldurchlaß und innere Führung ausbildende Abschnitte in einem einstückigen Körper ausgebildet sein oder die beiden jeweiligen Richtungswechseldurchlaß und innere Führung ausbildenden Ab-. schnitte an einer jeden rechten und linken Seite des beweglichen Blockes können als ein einstückiger Körper ausgebildet sein.

Die Vorrichtung der vorliegenden Erfindung kann derart aufgebaut sein, daß das Führungsteil eine Führungsschiene aufweist, das bewegliche Teil mit einem waagerechten Abschnitt versehen ist, der einer oberen Fläche der Führungsschiene und einem einzelnen Schenkelabschnitt gegenüberliegt, der wiederum einer Seitenfläche der Führungsschiene gegenüberliegt; eine einzelne Rollkörperlaufbahn in einer Lücke zwischen der einen Seitenfläche der Führungsschiene und dem einzelnen Schenkelabschnitt angeordnet ist und eine weitere, einzelne Rollkörperlaufbahn in einer Lücke zwischen der oberen Fläche der Führungsschiene und einer unteren Fläche des waagerechten Abschnitts in der Nähe einer Ecke der Führungsschiene angeordnet ist.

Die Vorrichtung der vorliegenden Erfindung kann derart aufgebaut sein, daß das Führungsteil eine Führungsschiene aufweist; das bewegliche Teil einen beweglichen Block aufweist, der mit einem Paar von Schenkelabschnitten versehen ist, zwischen denen die Führungsschiene an deren rechten und linken Seitenflächen gehalten ist; und eine einzelne Rollkörperlaufbahn in einer jeden Lücke zwischen den rechten und linken Seitenflächen der Führungsschiene und den beiden Schenkelabschnitten angeordnet ist, so daß insgesamt zwei Bahnen vorhanden sind.

Die Vorrichtung der vorliegenden Erfindung kann derart aufgebaut sein, daß das Führungsteil eine Führungsschiene aufweist; das bewegliche Teil einen beweglichen Block aufweist, der entlang einer Seitenfläche der Führungsschiene angeordnet ist; und zwei Rollkörperlaufbahnen in einer Lücke zwischen der einen Seitenfläche der Führungsschiene und dem beweglichen Block angeordnet ist.

Die Vorrichtung der vorliegenden Erfindung kann derart aufgebaut sein, daß das Führungsteil eine Keilwelle aufweist; und das bewegliche Teil ein äußeres Rohr aufweist, das an der Keilwelle über eine Vielzahl von Rollkörperlaufbahnen beweglich gehalten ist.

Zusätzlich ist entsprechend der vorliegenden Erfindung auch eine Führungsvorrichtung für eine geradlinige Bewegung vorgesehen, die folgende Merkmale aufweist:
eine Führungsschiene, die mit zwei Rollkörperlaufbahnen an einer jeden rechten und linken Seitenfläche der Führungsschiene versehen ist, so daß insgesamt vier Rollkörperlaufbahnen vorhanden sind; und
ein beweglicher Block, der mit einem Paar von Schenkelabschnitten versehen ist, zwischen denen die Führungsschiene an deren rechten und linken Seitenflächen gehalten ist, wobei ein jeder der Schenkelabschnitte an einer inneren Fläche zwei Rollkörpergegenlaufbahnen aufweist, die zwei Rollkörperlaufbahnen der Führungsschiene entsprechen, so daß insgesamt vier Rollkörpergegenlaufbahnen vorhanden sind, wobei ferner der bewegliche Block vier endlose Umläufe aufweist, die durch vier Rollkörperrückläufe gebildet sind, die jeweils parallel zu den vier Rollkörpergegenlaufbahnen angeordnet sind und die beiden Enden einer jeden der vier Rollkörpergegenlaufbahnen mit den beiden Enden einer jeden der vier Rollkörperlaufbahnen verbinden,
dadurch gekennzeichnet, daß:
ein aus Harz gebildeter Körper bei einem jeden der endlosen Umläufe ein Paar von einen Rollkörperdurchlaß bildenden Abschnitten aufweist, die sich entlang der beiden in Längsrichtung verlaufenden Seiten der Rollkörpergegenlaufbahn erstrecken, einen einen Rücklauf bildenden Abschnitt für den Rollkörperrücklauf und ein Paar von Richtungswechseldurchlaß und innere Führung ausbildenden Abschnitten aufweist, die innere, in Umfangsrichtung wirkende Führungsabschnitte der Richtungswechseldurchlässe bilden, wobei der aus Harz gebildete Körper getrennt von einem Körper des beweglichen Blockes ausgebildet ist;
der aus Harz gebildete Körper in zwei Teilkörper geteilt ist, die jeweils an den Schenkelabschnitten des beweglichen Blocks angeordnet sind, um so zwei endlose Umläufe an der Innenseite eines jeden der Schenkelabschnitte zu bilden; und
die Rollkörpergegenlaufbahn und das Paar von den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten bei einem jeden der zwei Körperteile als ein einstückiger Körper ausgebildet sind, wobei der den Rücklauf bildende Abschnitt getrennt vom einstückigen Körper geformt ist.

Gemäß der vorliegenden Erfindung ist der aus Harz gebildete Körper für den Rollkörperumlauf getrennt vom Körper des beweglichen Blockes ausgebildet. Selbst wenn der bewegliche Block groß ist, wird dadurch der Fluß des flüssigen Harzes nicht durch den Körper des beweglichen Blockes wie beim Stand der Technik behindert, bei dem der Körper des beweglichen Blockes und der aus Harz gebildete Körper einstückig miteinander ausgebildet sind, und es ist möglich, einen guten Fluß des flüssigen Harzes durch Vorsehen einer größeren Anzahl von Eingußstellen in der Form sicherzustellen, was somit zu einer hervorragenden Formgebung führt. Im allgemeinen ist es schwer, einen guten Fluß des flüssigen Harzes insbesondere an den den Rollkörperdurchlaß bildenden Abschnitten, die sich entlang der in Längsrichtung verlaufenden Seiten der Rollkörpergegenlaufbahn erstrecken, zu erreichen und daher ist es bedeutsam, den aus Harz gebildeten Körper getrennt vom Körper des beweglichen Blockes erfindungsgemäß zu formen.

Da insbesondere der aus Harz gebildete Körper in zwei Teilkörper unterteilt ist, von denen ein jeder zwei endlose Umläufe ausbildet, kann ein guter Lauf des flüssigen Harzes sichergestellt werden, selbst wenn der Block breiter ist.

Der Rollkörperumlauf wird durch den aus Harz gebildeten Körper gebildet. Dadurch kann eine direkte Lagebestimmung in der relativen Lagebeziehung zwischen den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten und dem den Rollkörperdurchlaß bildenden Abschnitt sowie der relativen Lagebeziehung zwischen den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten und dem den Rücklauf bildenden Abschnitt erreicht werden und die Durchgängigkeit des Rollkörperumlaufs wird auf vorteilhafte Weise sichergestellt, wodurch ein glatter Umlauf der Rollkörper erreicht wird.

Da die den Rollkörperdurchlaß bildenden Abschnitte entlang der beiden in Längsrichtung verlaufenden Seiten der Rollkörpergegenlaufbahn angeordnet sind, sind die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte, die in einer geeigneten relativen Lagebeziehung mit den den Rollkörperdurchlaß bildenden Abschnitten stehen, genau an den beiden Enden der Rollkörpergegenlaufbahn gesetzt.

Durch die Wahrung der geeigneten, relativen Lagebeziehung der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte mit dem Rollkörperrücklauf bewirkt, daß die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte genau mit der inneren Oberfläche des Rollkörperrücklaufs verbunden sind.

Insbesondere findet der Wechsel einer Laufrichtung der Rollkörper in der Verbindungsfläche der den Rollkörperdurchlaß bildenden Abschnitte mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten statt. Wenn diese beiden Abschnitte in einer solchen Verbindungsfläche miteinander durch einstückige Formgebung verbunden werden, ist ein Arbeitsschritt zum Zusammenbau dieser beiden Abschnitte nicht nötig, wodurch es möglich ist, eine glatte Durchgängigkeit dieser beiden Abschnitte sicherzustellen, ohne durch die Genauigkeit des Zusammenbaus beeinflußt zu werden.

Die vorliegende Erfindung kann die zusätzlichen Merkmale aufweisen, daß ein Rollkörperkäfig vorgesehen ist, der die Rollkörper hintereinander in einem vorgegebenen Abstand zwischen zwei benachbarten Rollkörpern halten kann und der Seitenkantenabschnitte aufweist, die von beiden Seiten eines jeden Rollkörpers vorspringen; und Führungsnuten zum Führen der Seitenkantenabschnitte des Rollkörperkäfigs am gesamten Umfang des Rollkörperumlaufs ausgebildet sind.

Eine derartiger Rollkörperkäfig ermöglicht aufgrund der guten Durchgängigkeit des Führungsabschnittes für den Rollkörperkäfig einen glatten Umlauf der Rollkörper.

Da der Führungsabschnitt für den Rollkörperkäfig, der im übrigen eine kleine Dicke aufweist, nicht durch Einsetzen des Körpers des beweglichen Blockes in eine Form und dem darauffolgenden Einspritzen von flüssigem Harz in die Form ausgeformt wird, sondern getrennt vom Körper des beweglichen Blocks gebildet wird, kann die Lage von Eingußstellen frei bestimmt werden, ohne durch den Körper des beweglichen Blockes behindert zu sein, mit dem Ergebnis, daß das flüssige Harz während der Bildung des Führungsabschnittes den gesamten dafür vorgesehenen Raum erreichen kann, der in der Form ausgebildet ist.

Die vorliegende Erfindung kann die zusätzlichen Merkmale aufweisen, daß ein jeder, der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte einen dünnen Plattenabschnitt aufweist, der in Kontakt mit der Endfläche des Körpers des beweglichen Blocks gebracht wird, und daß ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte mit den den Rollkörperdurchlaß bildenden Abschnitten oder dem den Rücklauf bildenden Abschnitt durch den dünnen Plattenabschnitt verbunden ist.

Wenn ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte mit den den Rollkörperdurchlaß bildenden Abschnitten durch den dünnen Plattenabschnitt verbunden ist, kann eine Verformung des dünnen Plattenabschnittes eine Verschiebung ausgleichen, die zwischen dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rollkörperdurchlaß bildenden Abschnitt oder zwischen dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rücklauf bildenden Abschnitt stattfindet. Entsprechend ist es möglich, eine genaue Lagebeziehung zwischen dem Ende des den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rollkörperdurchlaß bildenden Abschnitt oder zwischen dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rücklauf bildenden Abschnitt beizubehalten.

Der dünne Plattenabschnitt wird gegen die flache Endfläche des Körpers des beweglichen Teils durch eine Klemmkraft gedrückt, die auf die seitliche Deckplatte wirkt. Die Lage des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes kann dadurch über die Verformung des dünnen Plattenabschnittes korrigiert werden, selbst wenn der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt relativ zur Endfläche des Körpers des beweglichen Blocks falsch positioniert ist. Zusätzlich kann der dünne Plattenabschnitt fest zwischen der seitlichen Deckplatte und dem Körper des beweglichen Blocks durch die Klemmkraft gesichert werden, die auf die seitliche Deckplatte wirkt, wodurch eine falsche Plazierung des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes verhindert wird.

KURZE BESCHREIBUNG DER ZEICHNUNGEN

Fig. 1 zeigt eine schematische, auseinandergebaute Perspektivansicht, in der ein beweglicher Block einer Führungsvorrichtung für eine geradlinige Bewegung gemäß dem ersten Ausführungsbeispiel der vorliegenden Erfindung dargestellt ist;

Fig. 2 zeigt ein Rahmenteil aus Harz, wie es in **Fig.** 1 gezeigt ist, der einen der aus Harz gebildeten Körper zur Ausbildung eines Kugelumlaufs darstellt; insbesondere zeigt 2(a) eine Vorderansicht des Rahmenteils aus Harz,

Fig. 2(b) eine Seitenansicht des Rahmenteils aus Harz, **Fig.** 2(c) eine Schnittansicht entlang der Linie C-C der **Fig.** 2(a), **Fig.** 2(d) einen Querschnitt entlang der Linie D-D der **Fig.** 2(b), **Fig.** 2(e) einen vergrößerten Querschnitt entlang der Linie E-E der **Fig.** 2(a) und **Fig.** 2(f) einen vergrößerten Querschnitt entlang der Linie F-F der **Fig.** 2(a);

Fig. 3(a) zeigt eine Vorderansicht im Querschnitt, in der die Führungsvorrichtung für eine geradlinige Bewegung gemäß dem ersten Ausführungsbeispiel der vorliegenden Erfindung, wie es in der **Fig.** 1 gezeigt ist, dargestellt ist,

Fig. 3(b) zeigt eine Vorderansicht der Vorrichtung der **Fig.** 3(a), bei der in einer Hälfte ein Abschnitt einer seitlichen Deckplatte weggelassen ist und

Fig. 3(c) bis (f) sind ausschnittsweise Querschnitte, in denen Ausführungsbeispiele des Aufbaus eines den Kugeldurchlaß bildenden Abschnittes und dessen Umgebung dargestellt sind, wie in **Fig.** 3(a) gezeigt;

Fig. 4(a) zeigt eine Seitenansicht zusammen mit einem teilweisen Querschnitt der Führungsvorrichtung für eine geradlinige Bewegung gemäß dem ersten Ausführungsbeispiel der vorliegenden Erfindung, **Fig.** 4(b) zeigt einen Querschnitt eines Kugelumlaufs des beweglichen Blockes der **Fig.** 4(a), von dem ein Kugelkäfig entfernt ist, **Fig.** 4(c) ist eine ausschnittsweise Seitenansicht des Kugelkäfigs, **Fig.** 4(d) ist eine Draufsicht des Kugelkäfigs der **Fig.** 4(c) und **Fig.** 4(e) ist eine Ansicht des Kugelkäfigs in Richtung eines Pfeiles "a" der **Fig.** 4(d);

Fig. 5 zeigt eine seitliche Deckplatte des beweglichen Blocks und insbesondere zeigt **Fig.** 5(a) eine Vorderansicht der seitlichen Deckplatte, **Fig.** 5(b) zeigt eine Rückenansicht und **Fig.** 5(c) zeigt einen Querschnitt im Mittenabschnitt;

Fig. 43 zeigt eine Röhre aus Harz, die einen Teil des aus Harz geformten Körpers der **Fig.** 41 darstellt, der wiederum den Kugelumlauf bildet, und insbesondere zeigt **Fig.** 43(a) eine Vorderansicht einer äußeren, umfangsseitigen Halbröhre, **Fig.** 43(b) zeigt eine Seitenansicht der äußeren, umfangsseitigen Halbröhre der **Fig.** 43(a), **Fig.** 43(c) zeigt eine Vorderansicht einer inneren, umfangsseitigen Halbröhre, **Fig.** 43(d) zeigt eine Seitenansicht der inneren, umfangsseitigen Halbröhre der **Fig.** 43(c); und

Fig. 44(a) zeigt einen Querschnitt eines Kugelumlaufs, bei dem der Kugelkäfig vom beweglichen Block der **Fig.** 40(a) entfernt ist, **Fig.** 44(b) zeigt eine abschnittsweise, vergrößerte Ansicht des Richtungswechseldurchlasses der **Fig.** 44(a), **Fig.** 44(c) zeigt eine abschnittsweise Seitenansicht des Kugelkäfigs, **Fig.** 44(d) zeigt eine Draufsicht des Kugelkäfigs der **Fig.** 44(c), **Fig.** 44(e) zeigt eine Ansicht des Kugelkäfigs in Richtung eines Pfeiles "a" der **Fig.** 44(d), **Fig.** 44(f) zeigt eine abschnittsweise Seitenansicht des Richtungswechseldurchlasses der **Fig.** 44(b), bei dem die seitliche Deckplatte entfernt ist, und **Fig.** 44(g) zeigt eine abschnittsweise Seitenansicht, in der ein ausgesparter Abschnitt dargestellt ist, der in der seitlichen Deckplatte der **Fig.** 44(b) den Richtungswechseldurchlaß bildet.

GENAUE BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSBEISPIELE

Im folgenden werden nun Ausführungsbeispiele einer Führungsvorrichtung für eine geradlinige Bewegung gemäß der vorliegenden Erfindung unter Bezugnahme auf die Zeichnungen beschrieben.

[ERSTES AUSFÜHRUNGSBEISPIEL]

Die **Fig.** 1 bis 7 zeigen eine Führungsvorrichtung für eine geradlinige Bewegung gemäß dem ersten Ausführungsbeispiel der vorliegenden Erfindung.

Die Führungsvorrichtung **1** für eine geradlinige Bewegung ist mit einer Führungsschiene **2** als einem sich geradlinig erstreckenden Führungsteil und einem beweglichen Block **4** als einem beweglichen Teil versehen, der derart angeordnet ist, daß er entlang der Führungsschiene **2** über eine große Anzahl von Kugeln **3** als Rollkörper beweglich ist.

Die Führungsschiene **2** hat die Form eines langen Balkens mit einem rechteckigen Querschnitt. Zwei Kugellaufrillen **5**, **5** als Rollkörperlaufbahnen sind an der waagerechten oberen Oberfläche der Führungsschiene **2** ausgebildet und eine einzelne Kugellaufrille **5** als Rollkörperlaufbahn ist an jeder der rechten und linken senkrechten Oberflächen der Führungsschiene **2** ausgebildet, so daß eine Gesamtzahl von vier Rillen **5** vorgesehen ist.

Der bewegliche Block **4** ist als ein Blockkörper mit einem Querschnitt in Form eines umgekehrten U's ausgebildet, dessen sich öffnendes Ende nach unten gerichtet ist. Der Blockkörper ist mit einem waagerechten Abschnitt **6** versehen, der der oberen Oberfläche der Führungsschiene **2** gegenüberliegt, und mit einem Paar von Schenkelabschnitten **7**, **7** versehen, die sich von den rechten und linken Enden des waagerechten Abschnittes **6** nach unten erstrecken und den rechten und linken Seitenflächen der Führungsschiene **2** jeweils gegenüberliegen. Der waagerechte Abschnitt **6** weist an seiner unteren Oberfläche zwei Kugelgegenlaufrillen **8**, **8** als Rollkörpergegenlaufbahnen auf, die den Kugellaufrillen **5**, **5** entsprechen, die an der oberen Oberfläche der Führungsschiene **2** ausgebildet sind. Ein jeder der Schenkelabschnitte **7**, **7** weist an seiner inneren Oberfläche eine einzelne Kugelgegenlaufrille **8** als Rollkörpergegenlaufbahn auf, die den jeweiligen Kugellaufrillen **5**, **5** entsprechen, die an den rechten und linken Seitenflächen der Führungsschiene **2** ausgebildet sind.

Zusätzlich sind am beweglichen Block **4** vier Kugelrückläufe **9**, **9**, **9**, **9** als Rollkörperrückläufe ausgebildet, die parallel zu den vier Kugelgegenlaufrillen **8**, **8**, **8**, **8** jeweils vorgesehen sind sowie vier Paare von Richtungswechseldurchlässen **10**, **10**, **10**, **10**, die jeweils U-förmig ausgebildet sind und die jeweiligen beiden Enden der Kugelgegenlaufrillen **8**, **8**, **8**, **8** mit den jeweiligen beiden Enden der Kugelrückläufe **9**, **9**, **9**, **9** verbinden und auf diese Weise vier endlose Umläufe bilden. Die Kugelrückläufe **9**, **9**, die jeweils den auf der oberen Seite der Führungsschiene **2** ausgebildeten Kugellaufrillen **5**, **5** entsprechen, sind im waagerechten Abschnitt **6** ausgebildet. Die anderen Kugelrückläufe **9**, **9**, die jeweils den an den rechten und linken senkrechten Oberflächen der Führungsschiene **2** ausgebildeten Kugellaufrillen **5**, **5** entsprechen, sind jeweils in den Schenkelabschnitten **7**, **7** des beweglichen Blockes **4** ausgebildet.

Bei jedem der vier endlosen Umläufe gemäß diesem Ausführungsbeispiel sind die Kugeln **3** in Form einer Reihe mittels eines Kugelkäfigs **12** als einen Rollkörperkäfig gehalten, wie in der **Fig.** 4 gezeigt ist, so daß die Kugeln **3** umlaufen können, während sie durch den Kugelkäfig **12** geführt sind.

Der Kugelkäfig **12** umfaßt einen biegsamen Gurtabschnitt **12**b, der mit Kugellöchern **12**a zur jeweiligen Aufnahme der Kugeln **3** und mit zwischen zwei aufeinanderfolgenden Kugeln **3**, **3** angeordneten Abstandsabschnitten **12**c versehen ist. Der Gurtabschnitt **12**b hat eine Weite, die größer ist als der Durchmesser einer Kugel **3**, so daß die beiden Seitenkanten des Gurtabschnittes **12**b von einer Kugel **3** nach außen erstrecken.

Der Abstandsabschnitt **12**c ist mit einer kugelförmigen Aussparung **12**d zur Aufnahme einer Kugel versehen, die der Kugeloberfläche einer Kugel **3** entspricht. Die Kugel **3** ist an ihren beiden Seiten durch ein Paar von stützenden, kugelförmigen Aussparungen **12**d gestützt, so daß verhindert wird, daß eine Kugel **3** vom Gurtabschnitt **12**b loskommen kann. Bei diesem Ausführungsbeispiel ist das eine Ende des Gurtabschnittes **12**b nicht mit dessen anderen Ende verbunden, so daß ein streifenförmiger Gurt mit zwei Enden gebildet wird. Das eine Ende des Gurtabschnittes **12**b kann mit dessen anderen Ende verbunden werden, um einen endlosen Gurt zu bilden.

Der bewegliche Block **4** weist einen Blockkörper **13** mit Kugelgegenlaufrillen **8**, **8**, **8**, **8**, einen aus Harz geformten Körper **20** zur Ausbildung der Kugelumläufe, der in den Blockkörper **13** eingesetzt ist, und ein Paar von seitlichen Deckplatten **40**, **40** auf, die an den beiden Endflächen des Blockkörpers **13** befestigt sind, in dem der aus Harz gebildete Körper **20** eingesetzt ist.

Ein jeder der Kugelumläufe des aus Harz geformten Körpers **20** weist ein Paar von einen Kugeldurchlaß bildenden Abschnitten **21, 21** auf, die sich entlang der beiden in Längsrichtung erstreckenden Seiten der Kugelgegenlaufrille **8** erstrecken, des weiteren ein Paar von einen Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22, 22**, die an den beiden Seitenflächen des Blockkörpers **13** vorgesehen sind, und eine Röhre aus Harz **23** als einen einen Rücklauf bildenden Abschnitt, der in eine im Blockkörper **13** gebildete Durchgangsöffnung eingesetzt ist. Bei diesem Ausführungsbeispiel sind die den Kugeldurchlaß bildenden Abschnitte **21, 21** und das Paar der einen Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22, 22** einstückig miteinander als ein einheitlicher Körper ausgebildet und die Röhre **23** aus Harz ist getrennt vom oben erwähnten einheitlichen Körper ausgebildet. Insbesondere wird der Aufbau verwendet, daß die den Kugeldurchlaß bildenden Abschnitte **21, 21** und das Paar von den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22, 22** miteinander einstückig über eine einstückige Formgebung verbunden sind, um einen einstückigen Rahmen **24** aus Harz zu bilden, und die vier Röhren **23** aus Harz können jeweils in den Blockkörper **13** eingesetzt werden.

Die den Kugeldurchlaß bildenden Abschnitte **21, 21** sind mit Führungsrillen zum Führen der beiden Seitenkanten des Gurtabschnittes **12**b des Kugelkäfigs **12** in einem belasteten Bereich ausgestattet. Die Führungsrillen können nicht nur verhindern, daß der Kugelkäfig **12** während des Laufs an der Kugel schwingt, sondern auch daß er durchhängt, wenn der bewegliche Block **4** von der Führungsschiene **2** entfernt wird, indem die Seitenkanten des Gurtabschnittes **12**b in die Führungsrille **21**a eingreifen. Die Kugeln **3** werden durch den Kugelkäfig **12** abgestützt. Insbesondere ist der Kugelkäfig **12** durch den Backenabschnitt der Führungsrille **21**a mit dem Ergebnis abgestützt, daß die Kugeln **3** in der richtigen Lage gehalten werden und nicht vom beweglichen Block **4** abfallen.

Bei diesem Ausführungsbeispiel ist ein Abstand zwischen dem Paar der den Kugeldurchlaß bildenden Abschnitt **21, 21**, das parallel zueinander an einen beiden in Längsrichtung verlaufenden Seiten der Kugelgegenlaufrille **8** angeordnet sind, etwas größer als ein Durchmesser einer Kugel **3**. Die Kugeln **3** fallen aus der Kugelgegenlaufrille **8**, wenn der Kugelkäfig **12** nicht verwendet wird. Wenn eine Länge des Vorsprungs des Backenabschnittes **21**b derart bestimmt ist, daß ein Abstand zwischen dem Paar der den Kugeldurchlaß bildenden Abschnitte **21, 21** etwas größer ist als der Durchmesser einer Kugel **3**, wie in der **Fig.** 3(d) gezeigt ist, ist es jedoch möglich zu verhindern, daß die Kugeln **3** auch ohne Verwendung des Kugelkäfigs **12** aus der Kugelgegenlaufrille **8** herausfallen. Ein derartiger Aufbau kann nicht nur in dem Fall verwendet werden, in welchem die Kugeln **3** in den Kugelumlauf unter Verwendung des Kugelkäfigs **12** eingesetzt werden, sondern auch in dem Fall, in welchem die Kugeln darin ohne den Kugelkäfig **12** eingesetztwerden. Der Abstand zwischen dem Paar von den den Kugeldurchlaß bildenden Abschnitten **21, 21** kann etwas kleiner sein als der Durchmesser einer Kugel **3**, so daß die den Kugeldurchlaß bildenden Abschnitte **21, 21** eine Kugel **3** ohne Verwendung des Kugelkäfigs **12** direkt halten, wie in der **Fig.** 3(e) gezeigt ist.

Außerdem sind Führungsrillen **9**c, **10**c im Kugelrücklauf **9** und im Richtungswechseldurchlaß **10** als nicht belastete Flächen ausgebildet, um die Seitenkanten des Gurtabschnittes **12**b zu führen. Die Führungsrillen **9**c, **10**c sind mit der obengenannten Führungsrille **21**a im belasteten Bereich verbunden, so daß eine endlose Rille am gesamten Umfang gebildet wird.

Wenn der Kugelkäfig **12**, wie in der **Fig.** 3(f) gezeigt, nicht verwendet wird, dann kann der Abstand zwischen dem Paar der den Kugeldurchlaß bildenden Abschnitte **21, 21**, die an den beiden in Längsrichtung verlaufenden Seiten der Kugelgegenlaufrille **8** angeordnet sind, wobei diese Abschnitte keine Backenabschnitte **21** aufweisen, etwas kleiner sein als der Durchmesser einer Kugel **3**, wodurch verhindert wird, daß die Kugeln **3** von der Kugelgegenlaufrille **8** herausfallen können.

Die vier Teile der den Kugeldurchlaß bildenden Abschnitte **21, 21** sind aus einem ersten, dünnen Verbindungsplattenabschnitt **25**, der sich in Längsrichtung entlang der Unterfläche des waagerechten Abschnittes **6** des Blockkörpers **13** erstreckt, einem Paar von zweiten Verbindungsplattenabschnitten **26, 26**, die einen L-förmigen Querschnitt aufweisen und sich in Längsrichtung des Blockkörpers **13** entlang den Eckenabschnitten zwischen dem waagerechten Abschnitt **6** und den Schenkelabschnitten **7, 7** des Blockkörpers **13** erstrecken, und ein Paar von dritten Verbindungsplattenabschnitten **27, 27**, die sich in der Längsrichtung des Blockkörpers **13** entlang der Unterflächen der Schenkelabschnitte **7, 7** des Blockkörpers **13** erstrecken, aufgebaut.

Insbesondere sind die rechten und linken Seitenkanten des ersten Verbindungsplattenabschnittes **25** und die oberen Kanten des Paares der rechten und linken zweiten Verbindungsplattenabschnitte **26, 26** an den beiden Seiten der jeweiligen Kugelgegenlaufrillen **8, 8** angeordnet, die an den Unterflächen des waagerechten Abschnittes **6** vorgesehen sind, so daß sie die den Kugeldurchlaß bildenden Abschnitte **21, 21; 21, 21** bilden. Die Unterkanten der zweiten Verbindungsplattenabschnitte **26, 26**, die Innenkanten der dritten Verbindungsplattenabschnitte **26, 26** sowie die Innenkanten der dritten Verbindungsplattenabschnitte **27, 27** sind an den beiden Seiten der jeweiligen Kugelgegenlaufrillen **8, 8** angeordnet, die an der jeweiligen Innenfläche der Schenkelabschnitte **7, 7** vorgesehen sind, so daß sie die anderen, den Kugeldurchlaß bildenden Abschnitte **21, 21; 21, 21** bilden.

Der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **22** weist einen dünnen Plattenabschnitt **29** auf, der mit der Endfläche des Blockkörpers **13** verbunden wird. Die den Kugeldurchlaß bildenden Abschnitt **21, 21** und die Röhre **23** aus Harz sind miteinander durch den obengenannten, dünnen Plattenabschnitt **29** verbunden. Bei dieses Ausführungsbeispiels sind die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22, 22** und die den Kugeldurchlaß bildenden Abschnitte **21, 21** über den dünnen Plattenabschnitt **29** durch einstückige Formgebung verbunden. Die Röhre **23** aus Harz wird in eine Öffnung **34** eingesetzt, das am dünnen Plattenabschnitt **29** ausgebildet ist, um so eine Randverbindung herzustellen, und ist am dünnen Plattenabschnitt **29** befestigt.

Der dünne Plattenabschnitt **29** weist einen ersten Endplattenabschnitt **30** auf, der der Endfläche des waagerechten Abschnittes **6** des Blockkörpers **13** entspricht, des weiteren ein Paar von dritten Endplattenabschnitten **32, 32**, die den Endflächen der Schenkelabschnitte **7, 7** entsprechen, sowie zweite Endplattenabschnitte **31, 31**, um den ersten Endplattenabschnitt **30** und die jeweiligen dritten Endplattenabschnitte **32, 32** miteinander zu verbinden. Der erste Endplattenabschnitt **30** weist die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22, 22** auf, die derart ausgebildet sind, daß sie entsprechend den zwei Kugellaufbahnen **3, 3** an der Oberflächenseite der Führungsschiene **2** vorspringen. Ein jeder der dritten Endplattenabschnitte **32, 32** weist den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt **22** auf, der derart ausgebildet ist, daß er entsprechend der einzelnen Kugellaufbahn **3** an der Seitenfläche der Führungsschiene **2** hervorspringt.

Die ersten Endplattenabschnitte **30**, **30**, die jeweils an den beiden Enden des Blockkörpers **13** plaziert werden, sind mit ihrem unteren Abschnitt mit den beiden Enden des ersten Verbindungsplattenabschnittes **25** verbunden, der sich in Längsrichtung zwischen den ersten Endplattenabschnitten **30**, **30** erstreckt. Die zweiten Endplattenabschnitte **31**, **31**, die jeweils an den beiden Enden des Blockkörpers **13** plaziert werden, sind an ihrem inneren Kantenabschnitt mit den beiden Enden des zweiten Verbindungsplattenabschnittes **26** verbunden, der sich in Längsrichtung zwischen den zweiten Endplattenabschnitten **31**, **31** erstreckt. Die anderen, zweiten Endplattenabschnitte **31**, **31** weisen denselben Verbindungsaufbau auf. Die dritten Endplattenabschnitte **32**, **32**, die jeweils an den beiden Enden des Blockkörpers **13** plaziert werden, sind an ihrem inneren Kantenabschnitt mit den beiden Enden des dritten Verbindungsplattenabschnittes **27** verbunden, der sich in Längsrichtung zwischen den dritten Endplattenabschnitten **32**, **32** erstreckt. Die anderen dritten Endplattenabschnitte **32**, **32** weisen denselben Verbindungsaufbau auf. Auf diese Weise wird ein einzelner Rahmen **24** aus Harz gebildet.

Ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22** weist eine halbzylinderförmige Form auf. Am äußeren Umfang des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **22** ist eine innere Führungsrille **10**a mit einem halbkreisförmigen Querschnitt ausgebildet, um den inneren Führungsabschnitt für den Richtungswechseldurchlaß **10** zu bilden. Das eine Ende der inneren Führungsrille **10**a ist mit dem Ende der Kugelgegenlaufrille **8** verbunden. Dementsprechend hat das eine Ende der inneren Führungsrille **10**a dieselbe Querschnittsform wie die Kugelgegenlaufrille **8**, so daß das eine Ende der inneren Führungsrille **10**a mit dem Ende der Kugelgegenlaufrille **8** ausgerichtet ist. Das andere Ende der inneren Führungsrille **10**a des Richtungswechseldurchlasses **10** ist mit dem Ende des Kugelrücklaufs **9** verbunden. Dementsprechend weist das andere Ende der inneren Führungsrille **10**a dieselbe Querschnittsform auf wie der Kugelrücklauf **9**, um so das andere Ende der inneren Führungsrille **10**a mit dem Ende des Kugelrücklaufs **9** auszurichten.

An den beiden Enden der inneren Führungsrille **10**a sind zylindrische Flanschabschnitte **33**, **33** ausgebildet. Der Abstand zwischen den jeweiligen Außenflächen der zylindrischen Flanschabschnitte **33**, **33** ist größer als die Weite des Gurtabschnittes **12**b. Die zylindrischen Flanschabschnitte **33**, **33** bilden eine Käfigführungsrille für den Kugelkäfig **12** zusammen mit einem halbkreisförmigen, ausgesparten Abschnitt, der Aussparungen aufweist und am inneren Umfang der Aussparung der weiter unten beschriebenen seitlichen Deckplatte **40** ausgebildet ist.

Die beiden Enden der inneren Führungsrille **10**a für den Richtungswechseldurchlaß **10** erstrecken sich bis zur Berührungsfläche der ersten und dritten Endplattenabschnitte **30**, **32** mit der Endfläche des Blockkörpers **13**, um so mit den jeweiligen Enden der Kugelgegenlaufrille **8** und dem Kugelrücklauf **9** verbunden zu sein. Löcher **34**, **34**, **34**, **34** von halbkreisförmiger Form zum Einsetzen der Röhre, in welche die Enden der Röhren **23** aus Harz eingesetzt werden, sind an den ersten und dritten Endplattenabschnitten **30**, **32** ausgebildet.

Wie in der **Fig.** 7 gezeigt, besteht die Röhre **23** aus Harz aus einem inneren, umfangsseitigen Halbröhrenteil **23**a, das an der inneren Umfangsseite des Kugelumlaufs angeordnet ist, die durchgängig mit der inneren Führungsrille **10**a des Richtungswechseldurchlasses verbunden ist, sowie ein äußeres umfangsseitiges Halbröhrenteil **23**b, das an der äußeren Umfangsseite des Kugelumlaufes angeordnet ist, der durchgängig mit einer äußeren Führungsrille **10**b für den Richtungswechseldurchlaß **10** verbunden ist, der an der seitlichen Deckplatte **40** angeordnet ist. Das innere, umfangsseitige Halbröhrenteil **23**a weist einen Rillenabschnitt **9**a von halbkreisförmigem Querschnitt und Seitenkantenabschnitte **23**c auf, die sich in Längsrichtung entlang des Rillenabschnittes **9**a erstrecken.

Das äußere, umfangsseitige Halbröhrenteil **23**b ist als ein geradliniges Teil mit demselben kreisförmigen Querschnitt wie die äußere Führungsrille **10**b des Richtungswechseldurchlasses ausgebildet, der an der seitlichen Deckplatte **40** ausgebildet ist. Das äußere umfangsseitige Halbröhrenteil **23**b weist einen Rillenabschnitt **9**b auf, der durchgängig mit der äußeren Führungsrille **10**b verbunden ist, sowie Seitenkantenabschnitte **23**d, die sich in Längsrichtung entlang des Rillenabschnittes **9**b erstrecken. Die Seitenkantenabschnitte **23**d sind an ihren äußeren Kanten mit Vorsprüngen **23**e versehen, die mit den äußeren Kanten der Seitenkantenabschnitte **23**c des inneren, umfangsseitigen Halbröhrenteil **23**a in Kontakt gebracht werden, um die Käfigführungsrille **9**c des Kugelkäfigs **12** zu bilden.

Das innere, umfangsseitige Halbröhrenteil **23**a der Röhre **23** aus Harz weist dieselbe Länge wie der Blockkörper **13** auf. Das innere umfangsseitige Halbröhrenteil **23**a wird derart positioniert, daß es in Kontakt mit der Rückfläche des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **22** gebracht wird.

Das äußere umfangsseitige Halbröhrenteil **23**b der Röhre **23** aus Harz ist andererseits um einen Betrag, der der Dicke des dünnen Plattenabschnittes **29** entspricht, länger als der Blockkörper **13**. Die äußeren umfangsseitigen Halbröhrenteile **23**b sind in die Einsetzlöcher **34** der ersten und dritten Endplattenabschnitte **30**, **32** eingesetzt. Eine Lagebestimmung des äußeren, umfangsseitigen Halbröhrenteils **23**b in Längsrichtung wird dadurch gemacht, daß die beiden Enden des äußeren, umfangsseitigen Halbröhrenteils **23**b, die in die Einsetzlöcher **34** eingesetzt sind, in Kontakt mit der Umfangskante des Endabschnittes der äußeren Führungsrillen **10**b des Richtungswechseldurchlasses gebracht werden, die an der seitlichen Deckplatte **40** angebracht sind. Die an den beiden Seitenkanten des äußeren umfangsseitigen Halbröhrenteils **23**b angeformten Vorsprünge **23**e berühren die äußeren Kanten der zylindrischen Flanschabschnitte **33**, die an dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt **22** ausgestaltet sind, um einen Teil der Führungsrille **10**c zu bilden, und das äußere umfangsseitige Halbröhrenteil **23**b und das innere umfangsseitige Halbröhrenteil **23**a können in der Einsetzöffnung **14** nicht drehen.

Die Röhre aus Harz **23** und die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22** werden über die Einsetzlöcher **34**, die an den ersten und dritten Endplattenabschnitten **30**, **32** des dünnen Plattenabschnittes **29** ausgebildet sind, genau positioniert. Auf diese Weise kann ein korrekter Zusammenbau ausgeführt werden.

Wie in der **Fig.** 5 gezeigt, ist die seitliche Deckplatte **40** mit einem ausgesparten Einsetzabschnitt **40**a versehen, in die der dünne Plattenabschnitt **29** eingesetzt wird, sowie mit vier ausgesparten Abschnitten **41** mit äußeren Führungsrillen **10**b des Richtungswechselsdurchlasses, in die Abschnitte der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22** eingesetzt sind, sowie ferner mit Abschnitten für Schrauben, um die seitliche Deckplatte **40** am Blockkörper **13** zu befestigen. Durch die Einschraubabschnitte wird die seitliche Deckplatte **40** am Blockkörper **13** durch Einsetzen von Schrauben **44** in Löcher **43** befestigt, die an der seitlichen Deckplatte **40** ausgebildet sind und die Schrauben mit Gewindelöcher **45**, die an der Endfläche des Blockkörpers **13** ausgebildet sind, in Eingriff bringen. Die Löcher **43** sind zwischen den ersten und dritten Endplattenabschnitten **30**, **32** des dünnen Plattenabschnittes **29** angeordnet.

Wie in der **Fig.** 7 gezeigt, weist die äußere Führungsrille **10**b des Richtungswechselsdurchlasses im ausgesparten Absatz **41** an ihren Seitenkanten bogenförmige Aussparungen **46** mit größerem Durchmesser, die zusammen mit den zylindrischen Flanschabschnitten **33** der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22** die Käfigführungsrillen **10**c bilden, sowie bogenförmige Aussparungen **47** mit kleinerem Durchmesser auf, in die die zylindrischen Flanschabschnitte **33** eingesetzt werden. Der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **22**, der an der inneren Führungsrille **10**a des Richtungswechselsdurchlasses vorgesehen ist, ist in den ausgesparten Abschnitt **41** der seitlichen Deckplatte **40** eingesetzt und der dünne Plattenabschnitt **29** ist vom ausgesparten Einsetzabschnitt **40**a der seitlichen Deckplatte **40** aufgenommen. Der dünne Plattenabschnitt **29** ist zwischen der seitlichen Deckplatte **40** und der Endfläche des Blockkörpers **13** durch eine Klemmkraft gehalten, so daß er dazwischen fest befestigt ist.

Die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22** und der den Kugeldurchlaß bildende Abschnitt **21** sind durch den dünnen Plattenabschnitt **29** verbunden, wodurch es möglich ist, eine genaue Lagebeziehung des Endes der inneren Führungsrille **10**a des Richtungswechselsdurchlasses, der in dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt **22** ausgebildet ist, relativ zu den den Kugeldurchlaß bildenden Abschnitte **21**, **21** sowie eine genaue Lagebeziehung der inneren Führungsrille **10**a des Richtungswechselsdurchlasses relativ zum Kugelrücklauf **9** zu wahren.

Der dünne Plattenabschnitt **29**, der in der Umgebung des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **22** gelegen ist, wird durch eine auf die seitliche Deckplatte **40** (vgl. **Fig.** 7) wirkende Klemmkraft gleichmäßig gegen die flache Endfläche des Blockkörpers **13** gedrückt. Selbst wenn der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **22** sich nicht in einer korrekten Lage befindet, dann ändert der dünne Plattenabschnitt **22** seine Form an der Endfläche des Blockkörpers **13**, wodurch die korrekte Lage des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **22** ermöglicht wird. Der dünne Plattenabschnitt **29** wird durch eine Klemmkraft, die an der seitlichen Deckplatte **40** wirkt, festgeklemmt und befestigt und die durch eine derartige Klemmung erzeugte Reibkraft kann eine ungünstige Bewegung der inneren Führungsrille **10**a des Richtungswechselsdurchlasses verhindern.

Die seitliche Deckplatte **40** ist am Blockkörper **13** derart befestigt, daß der mit dem Blockkörper **13** zusammengebaute, den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **22** in den ausgesparten Abschnitt **41** der seitlichen Deckplatte **40** eingesetzt ist. Dieser Arbeitsschritt des Einsetzens erlaubt es, eine genaue Lage der seitlichen Deckplatte **40** relativ zum Bockkörper **13** zu erhalten.

Fig. 6 zeigt die Arbeitsschritte beim Zusammenbau des oben beschriebenen, aus Harz geformten Körpers zur Ausbildung des Kugelumlaufs.

Zunächst wird das innere, umfangsseitige Halbröhrenteil **23**a der Röhre **23** aus Harz in die Durchgangsöffnung **14** des Blockkörpers **13** eingesetzt (vgl. **Fig.** 6(a) und 8(b).

Dann wird der durch einstückige Formgebung erhaltene Rahmen **24** aus Harz in die Aussparung des Blockkörpers **13** eingesetzt, wobei die dünnen Plattenabschnitte **29** an den beiden Enden des Rahmens **24** aus Harz an den jeweiligen Endflächen des Blockkörpers **13** gleiten (vgl. **Fig.** 6(c) und 6(d)). Der erste Verbindungsplattenabschnitt **25** des Rahmens **24** aus Harz kommt in Kontakt mit der Unterfläche des waagerechten Abschnittes **6**, wodurch eine Lagebestimmung in senkrechter Richtung des Rahmens **24** aus Harz stattfindet. Der zweite Verbindungsplattenabschnitt **26** und der dritte Verbindungsplattenabschnitt **27** des Rahmens **24** aus Harz kommen mit den jeweiligen Innenflächen der Schenkelabschnitte **7**, **7** des Blockkörpers **13** in Kontakt, wodurch eine Lagebestimmung der den Kugeldurchlaß bildenden Abschnitte **21**, **21** und des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **22** stattfindet (vgl. **Fig.** 6(e) und 6(f)). Zu diesem Zeitpunkt ist die Einsetzöffnung **34** des dünnen Plattenabschnittes **29** mit der Durchgangsöffnung **14** des Blockkörpers **13** ausgerichtet.

Dann wird das äußere, umfangsseitige Halbröhrenteil **23**b in die Durchgangsöffnung **14** von der Einsetzöffnung **34** eingesetzt, wodurch der Zusammenbau des aus Harz geformten Körpers **20** zur Ausbildung des Kugelumlaufs vervollständigt ist (vgl. **Fig.** 6(g) und 6(h)).

Dann wird die eine seitliche Deckplatte **40** mit der einen Endfläche des Blockkörpers **13** in einem weiteren Arbeitsschritt durch Klemmen befestigt, der die Kugeln haltende Kugelkäfig **12** wird eingesetzt und die andere seitliche Deckplatte **40** wird mit der anderen Endfläche des Blockkörpers **13** durch denselben Arbeitsvorgang durch Klemmen befestigt, wodurch der Zusammenbau des beweglichen Blocks **4** vollendet ist.

Gemäß der folgenden Erfindung ist der aus Harz geformte Körper **20**, der den Kugelumlauf bildet, getrennt vom Blockkörper **13** geformt. Selbst wenn der bewegliche Block **4** größer ist, wird der Fluß des flüssigen Harzes durch den Blockkörper **13** nicht behindert, wie in dem Fall, in dem der Blockkörper **13** einstückig mit dem aus Harz geformten Körper **20** ausgebildet ist. Eine Erhöhung der Anzahl von Eingußstellen, die in einer Form ausgebildet sind, kann einen korrekten Lauf des flüssigen Harzes sicherstellen, wodurch die Formgebung verbessert wird. Insbesondere sind die den Kugeldurchlaß bildenden Abschnitte **21**, **21**, die an den gegenüberliegenden, sich in Längsrichtung erstreckenden Seiten der Kugellaufrille **8** angeordnet sind, dünn, was bewirkt, daß das flüssige Harz nicht jeden Abschnitt des Raumes zur Ausbildung der den Kugeldurchlaß bildenden Abschnitte **21**, **21** erreichen kann. Daher wird in effektiver Weise der aus Harz geformte Körper **20** getrennt vom Blockkörper **13** entsprechend dem Ausführungsbeispiel der vorliegenden Erfindung ausgebildet.

Der durchgängige Umlauf wird durch den aus Harz geformten Körper **20** gebildet und es ist dadurch möglich, eine Lagebestimmung der inneren Führungsrille **10**a des Richtungswechselsdurchlasses relativ zu den den Kugeldurchlaß bildenden Abschnitten **21**, **21** sowie eine Lagebestimmung der inneren Führungsrille **10**a des Richtungswechselsdurchlasses relativ zum Kugelrücklauf **9** durchzuführen, wodurch die Durchgängigkeit des Umlaufs sichergestellt wird, um einen glatten Umlauf der Kugeln **3** zu ermöglichen.

Wenn die richtige Lagebeziehung der inneren Führungsrille **10**a des Richtungswechselsdurchlasses relativ zu den den Kugeldurchlaß bildenden Abschnitte **21**, **21** gewahrt ist, sind die den Kugeldurchlaß bildenden Abschnitte **21**, **21** an den beiden in Längsrichtung verlaufenden Seiten der Kugellaufrille **8** angeordnet, so daß sie mit den Enden der inneren Führungsrille **10**a des Richtungswechselsdurchlasses ausgerichtet sind.

Wenn die richtige Lagebeziehung der inneren Führungsrille **10**a des Richtungswechselsdurchlasses relativ zum Kugelrücklauf **9** gewahrt ist, dann kann die innere Führungsrille **10**a des Richtungswechselsdurchlasses mit der inneren Rille **23**a des Kugelrücklaufs **9** ausgerichtet werden.

Der Verbindungsabschnitt der den Kugeldurchlaß bildenden Abschnitte **21**, **21** und des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **22** wird durch einstückige Formgebung erhalten, wodurch auf einen Arbeitsschritt zum Zusammenbauen des Verbindungsabschnittes verzichtet werden kann. Obwohl die Laufrichtung der Kugeln **3** in einem derartigen Verbindungsabschnitt wechselt, kann der obengenannte, einstückige Aufbau eine Durchgängigkeit des Umlaufs sicherstellen, ohne durch die Genauigkeit beim Zusammenbau beeinflußt zu werden. Daher ist es möglich, einen glatten Lauf der Kugeln **3** von der Kugellaufbahn zwischen der Kugellaufrille **5** und der Kugelgegenlaufrille **8** zum Richtungswechseldurchlaß **10** sowie vom Richtungswechseldurchlaß **10** zum Kugelrücklauf **9** sicherzustellen.

Im folgenden werden Abänderungen des aus Harz geformten Körpers **20**, der den Kugelumlauf bildet und in weitere Teile unterteilt ist, beschrieben. Bei der Beschreibung dieser Abänderungen werden geänderte Merkmale nur im Vergleich zum ersten Ausführungsbeispiel der vorliegenden Erfindung erläutert. Für die gleichen Merkmale wie die des ersten Ausführungsbeispiels der vorliegenden Erfindung werden dieselben Bezugszeichen verwendet und auf ihre Beschreibung wird verzichtet.

[Erste Abänderung]

Die **Fig.** 8 und 9 zeigen die erste Abänderung des aus Harz geformten Körpers **20**, der den Kugelumlauf bildet, wie er beim ersten Ausführungsbeispiel beschrieben ist.

Bei der ersten Abänderung ist der aus Harz geformte Körper, der den Kugelumlauf bildet, aus dem ersten aus Harz geformten Rahmen **20**A gebildet, der durch einstückige Verbindung sowohl der den Kugeldurchlaß bildenden Abschnitte **21**, **21** als auch der Röhren **23** aus Harz an ihren Enden mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22**A für die eine Seite und den zweiten aus Harz geformten Rahmen **20**B, der mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22**B für die andere Seite versehen ist und getrennt vom ersten aus Harz geformten Rahmen **20**A ausgebildet ist.

In diesem Fall sind die den Kugeldurchlaß bildenden Abschnitte **21**, **21** einstückig mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22**A über den dünnen Plattenabschnitt **29**A wie bei dem ersten Ausführungsbeispiel verbunden.

Die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22**A sind außerdem über den dünnen Plattenabschnitt **29**A einstückig mit den Röhren **23** aus Harz verbunden. In diesem Fall ist die Röhre **23** aus Harz als ein röhrenförmiger, einstückiger Körper ausgebildet, obwohl die Halbröhrenteile des ersten Ausführungsbeispiels verwendet werden. Dementsprechend gibt es keine Einsetzöffnung **34** im dünnen Plattenabschnitt **29**A und der Kugelrücklauf **9** ist am dünnen Plattenabschnitt **29**A offengelegt.

Der erste, aus Harz geformte Rahmen **20**A und der zweite, aus Harz geformte Rahmen **20**B sind, wie in der **Fig.** 9 gezeigt, mittels einer Verbindung miteinander verbunden, bei der eine Kombination einer Aussparung und eines darin eingesetzten Vorsprungs verwendet wird, wie beispielsweise einer Randverbindung. Bei dem dargestellten Beispiel ist ein ausgesparter Abschnitt **36** einer Schwalbenschwanznut im zweiten aus Harz geformten Rahmen **20**B ausgebildet und ein Eingriffsvorsprung **35**, der in den ausgesparten Abschnitt **36** eingreifen soll, ist andererseits an den den Kugeldurchlaß bildenden Abschnitten **21**, **21** ausgebildet.

In diesem Fall wird die Röhre **23** aus Harz des ersten aus Harz geformten Rahmens **20**A in die Durchgangsöffnung **14** des Blockkörpers **13** eingesetzt und die ersten, zweiten und dritten Verbindungsplattenabschnitte **25**, **26**, **27** werden entlang der Unterfläche des waagerechten Abschnittes **6** des Blockkörpers **13** und den Innenflächen der Schenkelabschnitte **7**, **7** eingesetzt.

Dann werden die Eingriffsvorsprünge **35**, die an den jeweiligen freien Endabschnitten der ersten, zweiten und dritten Verbindungsplattenabschnitte **25**, **26**, **27** angeformt sind, mit den ausgesparten Abschnitten **36** in Eingriff gebracht, die am dünnen Plattenabschnitt **29**B des zweiten, aus Harz geformten Rahmens **24**B ausgebildet sind, der an der anderen Endfläche des Blockkörpers **13** angeordnet ist.

Die ausgesparten Abschnitte **36** können am ersten, aus Harz geformten Rahmen **20**A angeformt sein und die Eingriffsabschnitte **35** können am zweiten, aus Harz geformten Rahmen **20**B angeformt sein. Die Verbindung ist nicht auf die oben beschriebene Art beschränkt, sondern es kann jedwede herkömmliche Verbindungsmethode verwendet werden, bei denen die Enden der getrennten Teile in einer geeigneten Verbindungslage gehalten und verbunden werden können.

[Zweite Abänderung]

Die **Fig.** 10 und 11 zeigen die zweite Abänderung des aus Harz geformten Körpers **20**, der den Kugelumlauf bildet, wie er beim ersten Ausführungsbeispiel beschrieben ist.

Bei der zweiten Abänderung ist der aus Harz geformte Körper **20**, der den Kugelumlauf bildet und der durch einstückige Formgebung der beiden den Kugeldurchlaß bildenden Abschnitte **21**, **21** und der Röhren **23** aus Harz als einen den Rücklauf bildenden Abschnitt zusammen mit einem Paar von den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22**, **22** geformt ist, am Mittelabschnitt eines jeden, den Kugeldurchlaß bildenden Abschnittes **21**, **21** und der Röhren **23** aus Harz in zwei Teile geteilt. Insbesondere sind die den Kugeldurchlaß bildenden Abschnitte **21**, **21** und die Röhren **23** aus Harz an ihrem Mittelabschnitt in jeweils zwei Hälften geteilt und eine jede der beiden dermaßen geteilten Hälften ist einstückig mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22**, **22** ausgebildet, wodurch zwei aus Harz geformte Rahmen **20**C, **20**D mit im wesentlichen derselben Form gebildet werden.

Vier den Kugeldurchlaß bildende Abschnitte **21**, **21** sind an den ersten, zweiten und dritten Verbindungsplattenabschnitten **25**, **26**, **27** ausgebildet. Ausgesparte Abschnitte **38** und darin einzusetzende Eingriffsvorsprünge **37** sind an den geteilten Enden der ersten, zweiten und dritten Verbindungsplattenabschnitte **25**, **27** und den geteilten Enden der Röhren **23** aus Harz angeformt.

[Dritte Abänderung]

Die **Fig.** 12 bis 14 zeigen die dritte Abänderung des aus Harz geformten Körpers **20**, der den Kugelumlauf bildet, wie er beim ersten Ausführungsbeispiel beschrieben ist.

Bei der dritten Abänderung wird die Röhre **23** aus Harz als ein den Rücklauf bildender Abschnitt, wie sie beim ersten Ausführungsbeispiel beschrieben ist, nicht verwendet und ein aus Harz geformter Rahmen **20**E wird durch einstückige Formgebung der ersten, zweiten und dritten Verbindungsplattenabschnitte **25**, **26**, **27** erhalten, die die den Kugeldurchlaß bildende Abschnitte **21**, **21** mit den dünnen Plattenabschnitten **29**, **29** aufweisen, die jeweils das Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **22**, **22** aufweisen. Der Kugelrücklauf **9** ist als eine im Blockkörper **13** ausgebildete Durchgangsöffnung aufgebaut.

In diesem Fall kann ein Eingriffsvorsprung **39**a, der mit einem sich verjüngenden, im Öffnungsende des Kugelrücklaufs **9** ausgebildeten Abschnitt **15** in Eingriff bringbar ist, im Öffnungsende der Kugelöffnung **39** des dünnen Plattenabschnittes **29** angeformt sein. Ein derartiger Aufbau erlaubt es, eine korrekte Verbindung des Endes des Kugelrücklaufs **9** mit dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt **22** herzustellen.

Bei dem dargestellten Beispiel ist zusätzlich ein gebogener Eingriffsvorsprung **48** am Verbindungsabschnitt der äußeren Führungsrille **10**b des Richtungswechseldurchlasses mit dem Kugelrücklauf **9** ausgebildet. Der Eingriffsvorsprung **48** kann in die Kugelöffnung **39** des dünnen Plattenabschnittes **29** eingesetzt werden und greift in den sich verjüngenden Abschnitt **15** des Öffnungsendes des Kugelrücklaufs **9** ein.

[Vierte Abänderung]

Fig. 15 zeigt die vierte Abänderung des aus Harz geformten Körpers **20**, der den Kugelumlauf bildet, wie er beim ersten Ausführungsbeispiel beschrieben ist.

Bei der vierten Abänderung wird die bei der dritten Abänderung beschriebene Röhre **23** aus Harz nicht verwendet und ein aus Harz geformter Rahmen **24**B wird durch einstückige Formgebung der den Kugeldurchlaß bildenden Abschnitte **21** zusammen mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22** bei der einen Seite erhalten, der andere aus Harz geformte Rahmen **24**C, der mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **22** für die andere Seite versehen ist, ist getrennt vom oben erwähnten aus Harz geformten Rahmen **24**B ausgestaltet, und die aus Harz geformten Rahmen **24**B, **24**C sind miteinander durch den Eingriff des Eingriffsvorsprung **35** in die Aussparung **36** verbunden. Abgesehen davon ist der restliche Aufbau derselbe wie der der dritten Abänderung.

[Abänderungen der Kugellaufbahn]

Beim ersten Ausführungsbeispiel und den ersten bis vierten Abänderungen wurde beschrieben, daß zwei Laufbahnen für die Kugeln an der Oberfläche der Führungsschiene **2** und eine einzelne Kugellaufbahn an einer jeden Seitenfläche der Führungsschiene **2** vorgesehen ist, so daß eine Gesamtzahl von vier Kugellaufbahnen vorgesehen ist. Bei der vorliegenden Erfindung können jedoch andere Bauformen von Kugellaufbahnen verwendet werden, wie dies in der **Fig.** 16 gezeigt ist. Bezüglich der Teilung des aus Harz geformten Körpers **20**, der den Kugelumlauf bildet, basieren sämtliche, in der **Fig.** 16 gezeigten Abänderungen auf dem Teilungsschema des ersten Ausführungsbeispiels. Es können jedoch sämtliche Teilungsschemata der ersten bis vierten Abänderungen bei den Abänderungen der Kugellaufbahn, wie sie in der **Fig.** 16 gezeigt sind, verwendet werden.

Bei dem Beispiel, das in den **Fig.** 16(a) und 16(b) gezeigt ist, sind zwei untere und obere Kugellaufbahnen als Rollkörper an einer jeden Lücke zwischen den rechten und linken Seitenflächen der Führungsschiene **2** und den inneren Flächen der rechten und linken Schenkelabschnitte **7**, **7** des beweglichen Blockes **13** vorgesehen, so daß insgesamt vier Kugellaufbahnen vorhanden sind.

Fig. 16(b) zeigt die aus Harz geformten Körper **20**, bei dem sämtliche, den Kugeldurchlaß bildenden Abschnitte der vier Kugellaufbahnen einstückig miteinander ausgebildet sind. Der aus Harz gebildete Körper **20** kann jedoch auch in zwei aus Harz geformte Körper **20**, **20** geteilt sein, die zwei Kugellaufbahnen für eine jede der rechten und linken Seiten der Führungsschiene **2**, wie in der **Fig.** 18 gezeigt ist, entsprechen.

Im Beispiel der **Fig.** 16(c) und 16(d) ist der bewegliche Block **4** mit dem horizontalen Abschnitt **6**, der der Oberfläche der Führungsschiene **2** gegenüberliegt, und mit einem einzigen Schenkelabschnitt **7** versehen, der der einen Seitenfläche der Führungsschiene **2** gegenüberliegt. Die einzelne Kugellaufbahn **3** als Rollkörper ist zwischen der einen Seitenfläche der Führungsschiene **2** und dem einzelnen Schenkelabschnitt **7** des beweglichen Blockes **7** vorgesehen und die andere, einzelne Kugellaufbahn **3** ist zwischen der Oberfläche der Führungsschiene **2** und der Unterfläche des waagerechten Abschnittes in der Nähe der Kante der Führungsschiene **2** vorgesehen, um so insgesamt zwei Kugellaufbahnen vorzusehen.

Bei dem in **Fig.** 16(e) und 16(f) gezeigten Beispielen ist der bewegliche Block **4** mit einem Paar von Schenkelabschnitten **7**, **7** versehen, zwischen denen die Führungsschiene **2** an ihren rechten und linken Flächen gehalten ist. Die einzelne Kugellaufbahn **3** ist in einer jeden Lücke zwischen den rechten und linken Oberflächen der Führungsschiene **2** und den inneren Flächen der rechten und linken Schenkelabschnitte **7**, **7** des beweglichen Blockes **4** vorgesehen, so daß insgesamt zwei Kugellaufbahnen vorhanden sind.

Beim Beispiel der **Fig.** 16(g) und 16(h) ist der bewegliche Block **4** entlang der einen Seitenfläche der Führungsschiene **2** angeordnet. Zwei obere und untere Kugellaufbahnen sind zwischen der einen Seitenfläche der Führungsschiene **2** und des beweglichen Blockes **4** vorgesehen.

[Zweites Ausführungsbeispiel]

Die **Fig.** 18 bis 20 zeigen eine Führungsvorrichtung für eine geradlinige Bewegung gemäß dem zweiten Ausführungsbeispiel der vorliegenden Erfindung.

Beim zweiten Ausführungsbeispiel werden Rollen als Rollkörper verwendet. Insbesondere weist die Führungsvorrichtung für eine geradlinige Bewegung eine Führungsschiene **202** als ein Führungsteil auf, welches sich geradlinig erstreckt, und ein beweglicher Block **104** ist derart angeordnet, daß er über eine große Anzahl von Rollen **203** als Rollkörper entlang der Führungsschiene **202** beweglich ist.

Die Führungsschiene **202** ist in der Form eines langen Balkens mit rechteckigem Querschnitt ausgestaltet. Zwei Rollenlaufflächen **205**, **205** sind als Rollkörperlaufflächen an der waagerechte, oberen Fläche der Führungsschiene **2** ausgebildet und eine einzelne Rollenlauffläche **205** als Rollkörperlauffläche ist an jeder der rechten und linken senkrechten Flächen der Führungsschiene **2** ausgebildet, so daß insgesamt vier Oberflächen **5** vorhanden sind.

Der bewegliche Block **204** ist als ein Blockkörper ausgestaltet, der einen Querschnitt in Form eines umgekehrten U's aufweist, dessen sich öffnende Enden nach unten gerichtet sind. Der Blockkörper ist mit einem waagerechten Abschnitt **206** versehen, der der oberen Fläche der Führungsschiene **202** gegenüberliegt, sowie mit einem Paar von Schenkelabschnitten **207**, **207**, die sich von den rechten und linken Enden des waagerechten Abschnittes **206** nach unten erstrecken und den rechten und linken Seitenflächen der Führungsschiene **202** jeweils gegenüberliegen. Der waagerechte Abschnitt **206** weist an seiner unteren Fläche zwei Rollengegenlaufflächen **208**, **208** als Rollkörpergegenlaufbahnen auf, die den auf der oberen Fläche der Führungsschiene **202** ausgebildeten Rollenlaufflächen **205**, **205** entsprechen. Ein jeder der Schenkelabschnitte **207**, **207** weist an seiner Innenfläche eine einzelne Rollengegenlauffläche **208** als Rollkörpergegenlaufbahn auf, die der jeweiligen Rollenlauffläche **205**, **205** entspricht, die an den rechten und linken Seitenflächen der Führungsschiene **202** ausgebildet sind.

Zusätzlich sind beim beweglichen Block **204** vier Rollenrückläufe **209**, **209**, **209**, **209** als Rollkörperrückläufe ausgebildet, die jeweils parallel zu den vier Rollengegenlaufflächen **208**, **208**, **208**, **208** ausgestaltet sind, sowie vier Paare von Richtungswechseldurchlässen **210**, **210**, **210**, **210**, die jeweils U-förmig ausgestaltet sind, um die beiden jeweiligen Enden der Rollengegenlaufflächen **208**, **208**, **208**, **208** mit den beiden jeweiligen Enden der Rollenrückläufe **209**, **209**, **209**, **209** zu verbinden, um auf diese Weise vier endlose Umläufe zu bilden.

Die Rollenrückläufe **209**, **209**, die jeweils den Rollenlaufflächen **205**, **205** entsprechen, die an der oberen Seite der Führungsschiene **202** ausgebildet sind, sind im waagerechten Abschnitt **206** ausgebildet. Die anderen Rollenrückläufe **209**, **209**, die jeweils den Rollenlaufflächen **205**, **205** entsprechen, die an den rechten und linken senkrechten Flächen der Führungsschiene **202** ausgeformt sind, sind an den Schenkelabschnitten **207**, **207** des beweglichen Blockes **204** jeweils ausgebildet.

Bei jedem der endlosen Umläufe dieses Ausführungsbeispiels sind die Rollen **3** in Form einer Kette mittels eines Rollenkäfigs **212** als Rollkörperkäfig gehalten, so daß die Rollen **203** umlaufen können, während sie durch den Rollenkäfig **212** geführt werden.

Wie in den **Fig.** 19(b) bis 19(d) gezeigt ist, weist der Rollenkäfig **212** einen biegsamen Gurtabschnitt **212**b, der mit Rollenöffnungen **212**a zur jeweiligen Aufnahme der Rollen **203** versehen ist, sowie Abstandsabschnitte **212**c auf, die wiederum zwischen zwei benachbarten Rollen **203**, **203** angeordnet sind. Der Gurtabschnitt **212**b hat eine Weite, die größer ist als der Durchmesser einer Rolle **203**, so daß die beiden Seitenkanten des Gurtabschnittes **212**b sich von einer Rolle **203** nach außen erstrecken.

Der Abstandsabschnitt **212**c ist mit einer Aussparung **212**d zum Abstützen einer Rolle versehen, die der zylindrischen Oberfläche einer Rolle **203** entspricht. Die Rolle **203** ist an ihren beiden Seiten durch ein Paar von stützenden Aussparungen **212**d abgestützt, so daß verhindert wird, daß die Rollen **203** vom Gurtabschnitt **212**b herausfallen können. Bei diesem Ausführungsbeispiel ist das eine Ende des Gurtabschnittes **212**b nicht mit dessen anderen Ende verbunden, wodurch ein streifenförmiger Gurt mit zwei Enden entsteht. Das eine Ende des Gurtabschnittes **212**b kann mit dem anderen Ende verbunden werden, so daß ein endloser Gurt gebildet wird.

Wie in den **Fig.** 18 und 20 gezeigt ist, besteht der bewegliche Block **204** aus einem Blockkörper **213** aus Metall mit Rollengegenlaufflächen **208**, **208**, **208**, **208**, aus einem aus Harz geformten Körper **220**, der die Rollenumläufe bildet und der in den Blockkörper **213** eingesetzt ist, sowie aus einem Paar von seitlichen Deckplatten **214**, **214**, die an den beiden Endflächen des Blockkörpers **213** befestigt sind, in welchen der aus Harz geformte Körper **220** eingesetzt wird.

Beim zweiten Ausführungsbeispiel sind vier Umläufe durch zwei aus Harz geformte Körper **220**, **220** gebildet, welche wiederum den Rollenumlauf bilden und welche an den rechten und linken Seiten angeordnet sind.

Ein jeder der Rollenumläufe der aus Harz geformten Körper **220** weist ein Paar von einem Rollendurchlaß bildenden Abschnitten **221**, **221** auf, die sich entlang der beiden in Längsrichtung erstreckenden Seiten der Rollengegenlaufflächen **208** erstrecken, sowie ein Paar von einen Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **222**, **222**, die an den beiden Seitenflächen des Blockkörpers **213** vorgesehen ist, sowie ferner einer Röhre **223** aus Harz als einen den Rücklauf ausbildenden Abschnitt, der in eine im Blockkörper **213** gebildete Durchgangsöffnung eingesetzt ist.

Die den Rollendurchlaß bildenden Abschnitte **221**, **221** sind mit Führungsflächen versehen, die die beiden Seitenkanten des Gurtabschnittes **212**b des Rollenkäfigs **212** in einem belasteten Bereich führen, wie im Detail in der **Fig.** 20 dargestellt ist. Die Führungsrillen können nicht nur verhindern, daß der Rollenkäfig **212** während des Laufs der Rollen schwingt, sondern auch, daß er durchhängt, indem die Seitenkanten des Gurtabschnittes **212**b in die Führungsrille **221**a eingreifen. Die Rollen **203** werden durch den Rollenkäfig **212** abgestützt. Insbesondere wird der Rollenkäfig **212** durch einen Backenabschnitt der Führungsrille **221**a abgestützt, was zum Ergebnis hat, daß die Rollen **203** in ihrer korrekten Lage gehalten werden und nicht vom beweglichen Block **204** abfallen.

Bei diesem Ausführungsbeispiel ist das eine Ende des Gurtabschnittes **212**b nicht mit dessen anderem Ende verbunden, wodurch ein streifenförmiger Gurt mit zwei Enden entsteht. Das eine Ende des Gurtabschnittes **212**b kann mit dessen anderem Ende verbunden sein, so daß ein endloser Gurt gebildet wird.

Im Rollenrücklauf **209** und im Richtungswechseldurchlaß **210** als nicht belastete Bereiche sind außerdem Führungsrillen **209**c, **210**c ausgebildet, um die Seitenkanten des Gurtabschnittes **212**b zu führen. Die Führungsrillen **209**c, **210**c sind mit der oben erwähnten Führungsrille **221**a im belasteten Bereich verbunden, um so eine endlose Rille am gesamten Umfang zu bilden.

Bei einem jeden der aus Harz geformten Körper **220**, **220**, die den Rollenumlauf bilden, sind die den Rollendurchlaß bildenden Abschnitte **221**, **221** und das Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **222**, **222** einstückig miteinander ausgebildet. Die Röhre **223** aus Harz, die den Rollenrücklauf **209** bildet, ist getrennt von den aus Harz geformten Körpern **220**, **220** gebildet. Insbesondere sind die einen Enden der beiden Paare der den Rollendurchlaß bildenden Abschnitte **221**, **221** einstückig mit den Enden des Paares der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **222**, **222** verbunden, um einen einzelnen Rahmen **220A** aus Harz zu bilden, so daß der dermaßen gebildete Rahmen **220A** aus Harz in den Blockkörper **213** eingesetzt werden kann. Der andere Rahmen **220A** aus Harz weist denselben Aufbau auf.

Die den Rollendurchlaß bildenden Abschnitte **221**, **221**, die an der oberen Fläche der Führungsschiene **202** angeordnet sind, sind einstückig mit den anderen, den Rollendurchlaß bildenden Abschnitten **221**, **221** verbunden, die an der Seitenfläche der Führungsschiene **202** mittels eines dünnen Verbindungsplattenabschnittes **226** angeordnet sind.

Der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **222** ist einstückig mit einem dünnen Plattenabschnitt **229** ausgeformt, der mit der Endfläche des Blockkörpers **213** in Kontakt gebracht wird.

Der dünne Plattenabschnitt **229** weist den ersten Endplattenabschnitt **230** auf, der in Kontakt mit der Endfläche des waagerechten Abschnittes **206** des Blockkörpers **213** gebracht werden soll, sowie den dritten Endplattenabschnitt **232**, der mit der Endfläche des Schenkelabschnitts **207** in Kontakt gebracht werden soll, sowie ferner den zweiten Endplattenabschnitt **231**, der an der Ecke zwischen dem waagerechten Abschnitt **206** und dem Schenkelabschnitt **207** an der Endfläche des Blockkörpers **213** angeordnet ist und den ersten Endplattenabschnitt **230** mit dem dritten Endplattenabschnitt **232** verbindet.

Das Paar der den Richtungswechseldurchlaß bildenden Abschnitte **221**, **221**, die an den beiden sich in Längsrichtung erstreckenden Seiten der Rollenlauffläche **208** angeordnet sind, sind an der inneren Kante des ersten Endplattenabschnittes **230** und der Innenkante des dritten Endplattenabschnittes **232** jeweils einstückig angeformt. Die beiden Enden des Verbindungsplattenabschnittes **226** sind einstükkig mit den Innenkanten der zweiten Plattenabschnitte **231**, **231** verbunden.

Ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **222** ist von halbzylindrischer Form. Am äußeren Umfang des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **222** ist eine innere Führungsrille **210**a mit einem rechteckigen Querschnitt ausgeformt, so daß der innere Führungsabschnitt des Richtungswechseldurchlasses **210** entsteht. Das eine Ende des Grundes der inneren Führungsrille **210**a ist mit dem Ende der Rollengegenlauffläche **208** verbunden. Dementsprechend hat das eine Ende der inneren Führungsrille **210**a im Querschnitt dieselbe Form wie die Rollengegenlauffläche **208**, so daß das eine Ende der inneren Führungsrille **210**a mit dem Ende der Rollengegenlauffläche **208** ausgerichtet ist. Das andere Ende der inneren Führungsrille **210**a des Richtungswechseldurchlasses **210** ist mit dem Ende des Rollenrücklaufs **229** verbunden. Dementsprechend hat das andere Ende der inneren Führungsrille **210**a im Querschnitt dieselbe Form wie der Rollenrücklauf **209**, so daß das andere Ende der inneren Führungsrille **210**a mit dem Ende des Rollenrücklaufs **209** ausgerichtet ist.

Zylindrische Flanschabschnitte **233**, **233** sind an den beiden Enden der inneren Führungsrille **210**a ausgeformt. Der Abstand zwischen den jeweiligen äußeren Flächen der zylindrischen Flanschabschnitte **233**, **233** ist größer als die Weite des Gurtabschnittes **212**b. Die zylindrischen Flanschabschnitte **233**, **233** bilden zusammen mit der seitlichen Deckplatte **240**, die weiter unten beschrieben ist, eine Führungsrille **210**c für den Rollenkäfig **212**.

Das eine Ende der inneren Führungsrille **210**a des Richtungswechseldurchlasses **210** erstreckt sich bis zur Berührungsfläche des ersten und dritten Endplattenabschnittes **230**, **232** mit der Endfläche des Blockkörpers **213**, und ist so mit dem Ende der Rollengegenlauffläche **208** verbunden. Das andere Ende der inneren Führungsrille **210**a des Richtungswechseldurchlasses **210** erstreckt sich bis zur Endfläche des dünnen Plattenabschnittes **229**, der vom Blockkörper **213** beabstandet ist. Ein Absatzabschnitt **222**a, dessen Tiefe identisch der Wandstärke des dünnen Plattenabschnittes **229** ist, ist am anderen Ende der inneren Führungsrille **210**a ausgebildet. Das innere, umfangsseitige Halbröhrenteil der Röhre **223** aus Harz steht von der Endfläche des Blockkörpers **13** um eine Länge hervor, die identisch der Dicke des dünnen Plattenabschnittes **229** ist. Das vorspringende Ende des Halbröhrenteils **223**a ist in den Absatzabschnitt **222**a des dünnen Plattenabschnittes **229** eingepaßt.

An den ersten und dritten Endplattenabschnitten **230**, **232** des dünnen Plattenabschnittes **229** sind halbkreisförmige Öffnungen **234**, **234** zum Einsetzen der Röhre angeformt, in die die Enden des äußeren, umfangsseitigen Halbröhrenteils **223**a der Röhre **223**a eingesetzt werden, die den Rollenrücklauf **209** bildet. Die Röhre **223** aus Harz wird in die kreisförmige Durchgangsöffnung **214** eingesetzt, die im Blockkörper **213** ausgebildet ist, so daß die innere Umfläche der Röhre **223** aus Harz den Rollenrücklauf **209** bildet.

Wie in der **Fig.** 20 gezeigt ist, besteht die Röhre **223** aus Harz aus dem inneren, umfangsseitigen Halbröhrenteil **223**a, welches durchgängig mit der inneren Führungsrille **210**a des Richtungswechseldurchlasses verbunden ist, und aus dem äußeren umfangsseitigen Halbröhrenteil **323**b, welches durchgängig mit der äußeren Führungsrille **210**b des Richtungswechseldurchlasses **210** verbunden ist, welcher an der seitlichen Deckplatte **240** ausgebildet ist. Das innere, umfangsseitige Röhrenteil **223**a weist einen inneren Rillenabschnitt **209**a mit rechteckigem Querschnitt auf sowie Seitenkantenabschnitte **223**b, die sich entlang dem inneren Rillenabschnitt **209**a in Längsrichtung erstrecken. Die in Längsrichtung verlaufenden Kantenabschnitte **223**c des inneren, umfangsseitigen Halbröhrenteils **223**a weisen dieselbe Weite auf wie der Flanschabschnitt **232** des Abschnittes **228**.

Das äußere, umfangsseitige Halbröhrenteil **223**b ist als ein geradliniges Teil mit demselben rechteckigen Querschnitt wie die äußere Führungsrille **210**b des Richtungswechseldurchlasses ausgebildet, der an der seitlichen Deckplatte **240** ausgeformt ist. Das äußere, umfangsseitige Halbröhrenteil **223**b weist einen äußeren Rillenabschnitt **209**b auf, der durchgängig mit der äußeren Führungsrille **210**b verbunden ist, sowie Seitenkantenabschnitte 223d, die sich in Längsrichtung entlang dem äußeren Rillenabschnitt **209**b erstrecken. Die Seitenkantenabschnitte **223**d sind an ihren äußeren Kanten mit Vorsprüngen **223**e versehen, die in Kontakt mit den Seitenkantenabschnitten **223**c des inneren, umfangsseitigen Halbröhrenteils **223**a gebracht werden, um die Führungsrille des Gurtabschnittes **212** des Rollenkäfigs **212** zu bilden.

Das innere, umfangsseitige Halbröhrenteil **223**a der Röhre **223** aus Harz weist dieselbe Länge wie der Blockkörper **213** auf. Das innere, umfangsseitige Halbröhrenteil **223**a ist derart angeordnet, daß es die Endfläche des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **222** berührt, der an der Seite des Blockkörpers **213** angeordnet ist.

Das äußere, umfangsseitige Halbröhrenteil **223**b der Röhre **223** aus Harz weist andererseits eine größere Länge als der Blockkörper **213** auf und ist um die Dicke der ersten und dritten Endplattenabschnitte des dünnen Plattenabschnittes **229** länger, der an den beiden Enden des Blockkörpers **213** angeordnet ist. Das äußere, umfangsseitige Halbröhrenteil **223**b ist in Einsetzöffnungen **234** der ersten und dritten Endplattenabschnitte **230**, **232** eingesetzt. Eine Lagebestimmung in Längsrichtung des äußeren, umfangsseitigen Halbröhrenteils **223**b findet dadurch statt, daß die beiden Enden des äußeren, umfangsseitigen Halbröhrenteils **223**b, die in die Einsetzöffnungen **234** eingesetzt sind, die im Umfangsrichtung verlaufende Kante des Endabschnitts der äußeren Führungsrillen **210** des Richtungswechseldurchlasses berühren, die an der seitlichen Deckplatte ausgebildet sind. Die Vorsprünge **223**e, die an den beiden, sich in Längsrichtung erstreckenden Seitenkanten **223** des äußeren, umfangsseitigen Halbröhrenteils **223** ausgebildet sind, berühren die zylindrischen Flanschabschnitte **233** an den Seitenkanten der inneren Führungsrille **210**a des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **222** und das äußere, umfangsseitige Halbröhrenteil **223**b sowie das innere umfangsseitige Halbröhrenteil **223**a können sich in der Einsetzöffnung nicht drehen.

Die Röhren **223** aus Harz und die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **222** werden durch die Einsetzöffnungen **234**, die an den ersten und dritten Endplattenabschnitten **230**, **232** des dünnen Plattenabschnittes **229** angeformt sind, genau positioniert und auf diese Weise kann ein korrekter Zusammenbau stattfinden.

Die seitliche Deckplatte **240** ist mit vier ausgesparten Abschnitten **241** versehen, die äußere Führungsrillen **210**b für den Richtungswechseldurchlaß aufweisen, in welchen die

Abschnitte **228** der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **222** eingepaßt werden, sowie Einschraubabschnitte zum Befestigen der seitlichen Deckplatte **240** am Blockkörper **213**. Bei den Einschraubabschnitten wird die seitliche Deckplatte am Blockkörper **213** befestigt, indem Schrauben **244** in Öffnungen **243**, die an der seitlichen Deckplatte **240** ausgebildet sind, eingesetzt werden, wobei die Schrauben **244** mit Gewindeöffnungen **245**, die an der Endfläche des Körpers **213** ausgebildet sind, im Eingriff stehen. Die Öffnungen **243** befinden sich zwischen den ersten und dritten Endplattenabschnitten **230**, **232** des dünnen Plattenabschnittes **229**.

Der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt **222**, der mit der inneren Führungsrille **210**a des Richtungswechseldurchlasses versehen ist, ist in den ausgesparten Abschnitt **241** der seitlichen Deckplatte **240** eingepaßt. Der dünne Plattenabschnitt **229** ist zwischen der seitlichen Deckplatte **240** und der Endfläche des Blockkörpers **213** durch eine Klemmkraft gehalten, so daß er fest dazwischen befestigt ist.

Die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **222** und der den Rollendurchlaß bildende Abschnitt **221** sind über den dünnen Plattenabschnitt **229** verbunden, wodurch es möglich ist, eine genaue Lagebeziehung des Endes der inneren Führungsrille **210**a des Richtungswechseldurchlasses relativ zu den den Rollendurchlaß bildenden Abschnitte **221** sowie eine genaue Lagebeziehung der inneren Führungsrille **210**a des Richtungswechseldurchlasses relativ zum Rollenrücklauf **209** zu wahren.

Der dünne Plattenabschnitt **229** wird gleichmäßig gegen die ebene Endfläche des Blockkörpers **213** durch eine auf die seitliche Deckplatte **240** wirkende Klemmkraft gedrückt. Selbst wenn der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **222** sich nicht in einer korrekten Lage befindet, ändert der dünne Plattenabschnitt **229** seine Form, wodurch die korrekte Lage des den Richtungswechseldurchlaß und innere Führung bildenden Abschnitts **222** ermöglicht wird. Der dünne Plattenabschnitt **229** ist durch eine Klemmkraft festgeklemmt befestigt, die auf die seitliche Deckplatte **240** wirkt und die durch ein derartiges Klemmverfahren erzeugte Reibungskraft kann eine ungünstige Bewegung der inneren Führungsrille **210**a des Richtungswechseldurchlasses verhindern.

Im folgenden werden Abänderungen des aus Harz geformten Körpers **220**, der den Rollenumlauf bildet und in Teile unterteilt ist beschrieben. Bei der Beschreibung der Abänderungen werden abgeänderte Merkmale nur im Vergleich zum zweiten Ausführungsbeispiel der vorliegenden Erfindung erläutert. Dieselben Bauteile erhalten dieselben Bezugszeichen wie die beim zweiten Ausführungsbeispiel der vorliegenden Erfindung und auf ihre Beschreibung wird im folgenden verzichtet.

[Erste Abänderung]

Die **Fig.** 21 und 22 zeigen die erste Abänderung des aus Harz geformten Körpers **20**, der den Rollkörperumlauf bildet, wie er beim zweiten Ausführungsbeispiel beschrieben ist.

Bei der ersten Abänderung ist der aus Harz geformte Körper **220**, der den Rollkörperumlauf bildet, aus einem ersten aus Harz geformten Rahmen **220**A, der durch eine einstükkige Bindung der beiden den Rollendurchlaß bildenden Abschnitte **221**, **221** und den Röhren **223** aus Harz an ihren jeweiligen Enden mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **221** an der einen Seite erhalten wird, und aus dem zweiten aus Harz geformten Rahmen **220**B zusammengesetzt, der mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **222**B an der anderen Seite versehen ist und getrennt vom ersten aus Harz geformten Rahmen **220**A ausgebildet ist.

In diesem Fall sind die den Rollendurchlaß bildenden Abschnitte **221**, **221** mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **222**A über den dünnen Plattenabschnitt **229**A wie beim zweiten Ausführungsbeispiel einstückig verbunden.

Die den Richtungswechseldurchlaß und innere Führung bildende Abschnitte **222** sind außerdem über den dünnen Plattenabschnitt **229**A einstückig mit den Röhren **222** aus Harz verbunden. In diesem Fall ist die Röhre **223** aus Harz als ein röhrenförmiger einstückiger Körper ausgestaltet, obwohl die Halbröhrenteile beim zweiten Ausführungsbeispiel verwendet werden. Dementsprechend gibt es keine Einsetzöffnung **234** im dünnen Plattenabschnitt **229**A und der Rollenrücklauf **209** ist am dünnen Plattenabschnitt **229**A offengelegt.

Der erste, aus Harz geformte Rahmen **220**A und der zweite, aus Harz geformte Rahmen **220**B sind, wie in der **Fig.** 22 gezeigt, durch eine Verbindung miteinander verbunden, die eine Kombination einer Aussparung und eines darin einzusetzenden Vorsprungs umfaßt, wie beispielsweise eine Randverbindung. Beim dargestellten Beispiel ist ein ausgesparter Abschnitt **236** einer Schwalbenschwanznut im zweiten, aus Harz geformten Rahmen **120**B ausgebildet und ein Eingriffsvorsprung **235**, der in den ausgesparten Abschnitten **236** eingreift, ist außerdem an den den Rollendurchlaß bildenden Abschnitten **221**,**221** ausgebildet.

In diesem Fall ist die Röhre **223** aus Harz in den aus Harz geformten Rahmen **220**A in der Durchgangsöffnung des Blockkörpers **213** eingesetzt und die den Rollendurchlaß bildenden Abschnitte **221**, **221** und der Verbindungsplattenabschnitt **226** sind entlang der Unterfläche des waagerechten Abschnittes **206** des Blockkörpers **213** und den Innenflächen der Schenkelabschnitte **207**, **207** eingesetzt.

Dann greifen die Eingriffsvorsprünge **235**, die an den den Rollendurchlaß bildenden Abschnitten **221**, **221** und dem Verbindungsplattenabschnitt **226** ausgebildet sind, in die ausgesparten Abschnitte **236** ein, die am dünnen Plattenabschnitt **229**B des zweiten, aus Harz gebildeten Rahmens **224**B ausgebildet sind, der wiederum an der anderen Endfläche des Blockkörpers **213** angeordnet ist.

Die ausgesparten Abschnitte **236** können am ersten, aus Harz gebildeten Rahmen **220**A ausgebildet sein und die Eingriffsvorsprünge **235** können am zweiten aus Harz geformten Rahmen **220**B ausgebildet sein. Die Verbindung ist nicht auf die oben beschriebene Verbindung beschränkt, sondern es kann jedwede herkömmliche Verbindung verwendet werden, bei denen die Enden der geteilten Teile in einer geeigneten Verbindungslage gehalten und verbunden werden können.

[Zweite Abänderung]

Die **Fig.** 23 und 24 zeigen die zweite Abänderung des aus Harz geformten Körpers **220**, der den Rollkörperumlauf bildet, wie er beim zweiten Ausführungsbeispiel beschrieben ist.

Bei der zweiten Abänderung ist der aus Harz geformte Körper **220**, der den Rollenumlauf bildet und der durch einstückige Formgebung sowohl der den Rollendurchlaß bildenden Abschnitte **221**, **221** als auch der Röhren **223** aus Harz als einen den Rücklauf bildenden Abschnitt zusammen mit einem Paar von den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt **221**, **221** erhalten wurde, am Mittelabschnitt eines jeden der den Rollendurchlaß bildenden Abschnitte **221**, **221** und den Röhren **223** aus Harz in zwei Teile geteilt. Insbesondere sind die den Rollendurchlaß bildenden Abschnitte **221**, **221** und die Röhren **223** aus Harz an ihrem Mittelabschnitt in die jeweiligen zwei Hälften geteilt und eine jede der derartig geteilten Hälften ist einstükkig mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **221**, **221** ausgebildet, wodurch zwei aus Harz gebildete Rahmen **220**C, **220**D mit im wesentlichen derselben Form gebildet werden.

An den geteilten Enden der den Rollendurchlaß bildenden Abschnitte **221**, **221**, den geteilten Enden des Verbindungsplattenabschnittes **226** und den geteilten Enden der Röhren **223** aus Harz sind ausgesparte Abschnitte **238** und darin einzusetzende Eingriffsvorsprünge **237** angeformt.

[Dritte Abänderung]

Die **Fig.** 25 bis 26 zeigen die dritte Abänderung des aus Harz gebildeten Körpers **220**, der den Rollenumlauf bildet, wie er beim zweiten Ausführungsbeispiel beschrieben ist.

Bei der dritten Abänderung wird die Röhre **223** aus Harz, die den den Rücklauf bildenden Abschnitt darstellt, der beim zweiten Ausführungsbeispiel beschrieben ist, nicht verwendet und ein aus Harz gebildeter Rahmen **220**E entsteht durch einstückige Formgebung der den Rollendurchlaß bildenden Abschnitte sowie des Verbindungsplattenabschnittes **226** zusammen mit den dünnen Plattenabschnitten **229**, **229**, die jeweils das Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **222**, **222** aufweisen. Der Rollenrücklauf **209** ist als eine im Blockkörper **213** ausgeformte Durchgangsöffnung ausgebildet.

In diesem Fall kann ein Eingriffsvorsprung **239**a, der mit einem sich verjüngenden Abschnitt **215** in Eingriff bringbar ist, der im Öffnungsende des Rollenrücklaufs **209** angeformt ist, im Öffnungsende der Rollenöffnung **239** des dünnen Plattenabschnittes **229** angeformt sein. Ein derartiger Aufbau ermöglicht eine korrekte Verbindung des Endes des Rollenrücklaufs **209** und des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **222**.

Beim dargestellten Beispiel ist ein bogenförmiger Eingriffsvorsprung **248** zusätzlich am Verbindungsabschnitt der äußeren Führungsrille **210**b des Richtungswechseldurchlasses mit dem Rollenrücklauf ausgebildet. Der Eingriffsvorsprung **248** kann in die Rollenöffnung **239** des dünnen Plattenabschnittes **229** eingepaßt werden und in den sich verjüngenden Abschnitt **215** des Öffnungsendes des Rollenrücklaufes **209** eingreifen.

[Vierte Abänderung]

Fig. 26 zeigt die vierte Abänderung des aus Harz gebildeten Körpers **220**, der den Rollenumlauf bildet, wie er beim zweiten Ausführungsbeispiel beschrieben ist.

Bei der vierten Abänderung wird die Röhre **223**, wie sie in der dritten Abänderung beschrieben ist, nicht verwendet und ein aus Harz geformter Rahmen **220**F wird durch einstückige Formgebung der den Rollendurchlaß bildenden Abschnitte **221** mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **222** an der einen Seite erhalten. Der andere aus Harz geformte Rahmen **220**F, der mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **222** der anderen Seite versehen ist, ist getrennt vom obengenannten, aus Harz gebildeten Rahmen **220**F ausgebildet und die aus Harz gebildeten Rahmen **220**F, **220**F sind miteinander durch den Eingriff der Eingriffsvorsprünge **235** in die Aussparung **236** verbunden. Der restliche Aufbau entspricht dem der dritten Abänderung.

[Abänderungen der Rollenbahn]

Beim zweiten Ausführungsbeispiel und den ersten bis vierten Abänderungen wurde beschrieben, daß zwei Rollenlaufbahnen an der Oberfläche der Führungsschiene **2** und eine einzelne Rollenlaufbahn an einer jeden Seitenfläche der Führungsschiene **2** vorgesehen sind, so daß insgesamt vier Rollenlaufbahnen vorhanden sind. Wie in den Figuren gezeigt ist, können jedoch auch andere Bauformen von Rollenlaufbahnen verwendet werden. Alle Abänderungen basieren bezüglich der Teilung des aus Harz gebildeten Körpers **220**, der den Rollenumlauf bildet, auf dem Teilungsschema des ersten Ausführungsbeispiels. Bei den Abänderungen der Rollenlaufbahn können jedoch alle Teilungsschemata der ersten bis vierten Abänderung verwendet werden.

Beim Beispiel der **Fig.** 27 sind zwei untere und obere Rollenlaufbahnen als Rollkörperlaufbahnen an einer jeden Lücke zwischen den rechten und linken Seitenflächen der Führungsschiene **202** und den inneren Flächen der rechten und linken Schenkelabschnitte **207**, **207** des beweglichen Blockes **204** vorgesehen, so daß insgesamt vier Rollenlaufbahnen vorhanden sind.

In diesem Fall sind vier innere Führungsabschnitte **210**a, die den vier Rollenlaufbahnen **203** entsprechen, einstückig miteinander in den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **222** ausgebildet.

Bei der obigen Beschreibung wird die vorliegende Erfindung bei einer Führungsvorrichtung für eine geradlinige Bewegung verwendet, bei der der bewegliche Block über Rollkörper auf der Führungsschiene als Spurstange angeordnet ist. Die vorliegende Erfindung kann jedoch auch bei einer sogenannten Kugelverzahnung verwendet werden, bei der eine äußere Hülse als bewegliches Teil auf eine Keilwelle als Spurstange gesetzt ist, wie unten beschrieben wird.

[Drittes Ausführungsbeispiel]

Eine Kugelkeilverzahnung **301**, wie sie in **Fig.** 28 bis 30 gezeigt ist, stellt eine sogenannte "Winkelkontakt"-Kugelkeilverzahnung dar und weist eine keilverzahnte Welle **302** als das sich geradlinig erstreckende Führungsteil und eine äußere Hülse **304** auf, die derart angeordnet ist, daß sie entlang der Keilwelle **302** über Kugeln **303** als der großen Anzahl von Rollkörpern beweglich ist.

Die keilverzahnte Welle **304** ist als ein langer Balken mit kreisförmigem Querschnitt ausgestaltet. Die keilverzahnte Welle **304** weist an ihrem äußeren Umfang drei Vorsprünge **306** auf. Zwei Kugellaufrillen **305**, **305** sind an den beiden Seiten eines jeden Vorsprunges **306** ausgebildet, um so insgesamt sechs Rillen vorzusehen.

Die äußere Hülse **304** weist an ihrem inneren Umfang drei Aussparungen **307** auf, die den Vorsprüngen **306** der keilverzahnten Welle **302** jeweils entsprechen. Kugelgegenlaufrillen **308**, **308** sind an den beiden Ecken einer jeden Aussparung **307** ausgebildet, um so den obengenannten Kugellaufrillen **305**, **305** zu entsprechen.

Zusätzlich weist die äußere Hülse **304** sechs Kugelrückläufe **309**, **309**; **309**, **309**; **309**, **309** auf, die parallel zu den sechs Kugelgegenlaufrillen **308**, **308**; **308**, **308**; **308**, **308** und sechs Richtungswechseldurchlässen **310**, **310**; **310**, **310**; **310**, **310** angeordnet sind, die als U-förmige Hülsen ausgebildet sind und die Enden der obengenannten Kugelgegenlaufrillen **308**, **308**; **308**, **308**; **308**, **308** mit den Enden der obengenannten Kugelrückläufe **309**, **309**; **309**, **309**; **309**, **309** verbinden. Die äußere Hülse **304** weist auf diese Weise sechs Umläufe auf.

Eine an den beiden Seitenflächen der Vorsprünge **306** der keilverzahnten Welle **302** berührt an gegenüberliegenden Punkten jeweils die Kugellaufrille **305** und die Kugelgegenlaufrille **308**. Eine die die obengenannten Kontaktpunkte verbindende Linie wird als die "Kontaktwinkellinie" bezeichnet. Ein Kontaktwinkel α, d. h. ein Winkel zwischen der Kontaktwinkellinie und dem Radius, der den Mittelpunkt der keilverzahnten Welle **302** und den Mittenabschnitt des Vorsprunges **306** verbindet, ist relativ groß. Der Kugelrücklauf **309** befindet sich auf dieser Kontaktwinkellinie.

Bei diesem dritten Ausführungsbeispiel sind die Kugeln **303**, die in einem jeden Umlauf eingesetzt sind, mittels eines Kugelkäfigs **312** miteinander verbunden, umso die Kette von Kugeln **303** zu bilden. Die Kugeln **303** werden durch den Kugelkäfig **312** geführt und laufen in jedem Umlauf um. Der Kugelkäfig **312** weist denselben Aufbau, wie in der **Fig.** 14 gezeigt ist, auf und daher wird auf dessen Beschreibung verzichtet.

Die äußere Hülse **304** besteht aus einem hülsenförmigen Körper **313**, der die Kugelgegenlaufrillen **308, 308; 308, 308; 308, 308** aufweist, aus drei aus Harz gebildeten Körpern **320, 320, 320**, die den Kugelumlauf bilden und in den Körper **313** eingesetzt sind, sowie ferner aus einem Paar von seitlichen Deckplatten **314, 314**, die an den beiden Enden des Körpers **313** befestigtwerden, nachdem die aus Harz gebildeten Körper **320, 320, 320** in den Körper **313** eingesetzt wurden.

Beim dritten Ausführungsbeispiel sind die sechs Umläufe durch die drei aus Harz gebildeten Körper **320, 320, 320** gebildet.

Ein jeder der Umläufe **311** der aus Harz gebildeten Körper **320**, die den Kugelumlauf bilden, weist ein Paar von den Kugelumlauf bildenden Abschnitten **321, 321** auf, die sich entlang der in Längsrichtung verlaufenden Seitenkanten der Kugelgegenlaufrillen **308** erstrecken, sowie ein Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322, 322**, die an den beiden Enden des Körpers **313** vorgesehen sind, sowie ferner Röhren **323** aus Harz als einen den Rücklauf bildenden Abschnitt, die in im Körper **313** ausgeformten Durchgangsöffnungen eingesetzt sind.

Die den Kugeldurchlaß bildenden Abschnitte **321, 321** sind mit Führungsrillen zum Führen der beiden Seitenkanten des Gurtabschnittes **312**b des Kugelkäfigs **312** in einem belasteten Bereich versehen. Die Führungsrillen können nicht nur verhindern, daß der Kugelkäfig **312** während des Umlaufs der Kugeln schwingt, sondern auch daß er durchhängt, indem die Seitenkanten des Gurtabschnittes **312**b in die Führungsrillen **321**a eingreifen, wenn die äußere Hülse **304** von der keilverzahnten Welle **302** entfernt wird. Die Kugeln **303** sind durch den Kugelkäfig **312** gehalten. Insbesondere wird der Kugelkäfig **312** durch einen Backenabschnitt der Führungsrille **321**a abgestützt, was zum Ergebnis hat, daß die Kugeln **303** in ihrer korrekten Lage gehalten werden und nicht aus der äußeren Hülse **304** herausfallen.

Im Kugelrücklauf **309** und dem Richtungswechseldurchlaß **310** als den nicht belasteten Bereichen sind außerdem Führungsrillen **309**c, **310**c ausgeformt, um die Seitenkanten des Gurtabschnittes **312**b zu führen. Die Führungsrillen **309**c, **310**c sind mit der oben erwähnten Führungsrille **321**a im belasteten Bereich verbunden, so daß am gesamten Umfang eine endlose Rille gebildet wird.

Bei jedem aus Harz gebildeten Körper **320**, der einen Kugelumlauf bildet, sind die den Kugeldurchlaß bildenden Abschnitte **321, 321** und das Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **322, 322** einstückig miteinander verbunden. Der aus Harz gebildete Körper **320** ist an den anderen Abschnitten in getrennte Teile geteilt, so daß er in den Körper **313** eingesetzt werden kann. Beim dritten Ausführungsbeispiel wird ein einzelner Rahmen **324** aus Harz dadurch erhalten, daß die Enden der vier den Kugeldurchlaß bildenden Abschnitte **321, 321** mit dem Ende des Paars der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **322, 322** einstückig verbunden werden und der dermaßen erhaltene Rahmen **324** aus Harz am Verbindungsabschnitt des den Rücklauf bildenden Abschnittes **323** mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322, 322** in getrennte Teile unterteilt wird, so daß er in den Körper **313** eingesetzt werden kann.

Jeweils zwei benachbarte, den Rollendurchlaß bildende Abschnitte **321, 321, 321, 321** sind miteinander durch einen dünnen, verbindenden Plattenabschnitt **326** einstückig verbunden. Der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **322** ist mit dem dünnen Plattenabschnitt **329** einstückig ausgeformt, welcher wiederum mit der Endfläche des Körpers **313** in Kontakt gebracht wird.

Der dünne Plattenabschnitt **329** ist mit den ersten Endplattenabschnitten **330, 330** und den zweiten Endplattenabschnitten **231** versehen, um die ersten Endplattenabschnitte **330, 330** miteinander zu verbinden. Ein jeder der den Kugeldurchlaß bildenden Abschnitte **321, 321** ist einstückig mit der Innenkante des ersten Endplattenabschnittes **130** verbunden. Die beiden Enden des Verbindungsplattenabschnittes **326** sind mit der Innenkante des zweiten Endplattenabschnittes **331** einstückig verbunden.

Ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte ist von halbzylinderförmiger Gestalt. Am äußeren Umfang des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **322** ist eine innere Führungsrille **310**a von halbkreisförmigem Querschnitt angeformt, um den inneren Führungsabschnitt des Richtungswechseldurchlaß **310** zu bilden. Das eine Ende der inneren Führungsrille **310**a ist mit dem Ende der Kugelgegenlaufrille **308** verbunden. Entsprechend weist das eine Ende der inneren Führungsrille **310**a im Querschnitt dieselbe Form auf wie die Kugelgegenlaufrille **308**, so daß das eine Ende der inneren Führungsrille **310**a mit dem Ende der Kugelgegenlaufrille **308** ausgerichtet ist. Das andere Ende der inneren Führungsrille **310**a des Richtungswechseldurchlasses **310** ist mit dem Ende des Kugelrücklaufes **309** verbunden. Dementsprechend weist das andere Ende der inneren Führungsrille **310**a im Querschnitt dieselbe Form auf wie der Kugelrücklauf **309**, so daß das andere Ende der inneren Führungsrille **310**a mit dem Ende des Kugelrücklaufs **309** ausgerichtet ist.

Zylindrische Flanschabschnitte **333, 333** sind an den beiden Enden der inneren Führungsrille **310**a ausgeformt. Der Abstand zwischen den jeweiligen Außenflächen der zylindrischen Flanschabschnitte **333, 333** ist größer als die Weite des Gurtabschnittes **312**b. Die zylindrischen Flanschabschnitte **333, 333** bilden zusammen mit der weiter unten beschriebenen seitlichen Deckplatte **340** eine Käfigführungsrille **310**c für den Kugelkäfig **312**.

Die beiden Enden der inneren Führungsrille **310**a des Richtungswechseldurchlasses **310** erstrecken sich bis an die Berührungsfläche des ersten Endplattenabschnittes **330** mit der Endfläche des Körpers **313**, so daß sie mit der jeweiligen Enden der Kugelgegenlaufrille **308** und dem Kugelrücklauf **309** verbunden sind.

Halbkreisförmige Einsetzlöcher **334, 334** für die Röhre, in die die Enden der beiden äußeren umfangsseitigen Halbröhrenteile **323**a der Röhren **323** aus Harz, die den Kugelrücklauf **309** bilden, eingesetzt werden, sind an den ersten und dritten Endplattenabschnitten **330, 332** des dünnen Plattenabschnittes **329** ausgeformt. Die Röhre **323** aus Harz wird in die kreisförmige Durchgangsöffnung **314** des Körpers **313** eingesetzt, so daß die innere Umfläche der Röhre **323** aus Harz den Kugelrücklauf **309** bildet.

Die Röhre **323** aus Harz besteht aus dem inneren, umfangsseitigen Halbröhrenteil **323**a, welches durchgängig mit der inneren Führungsrille **310**a des Richtungswechseldurchlasses verbunden ist, sowie aus dem äußeren, umfangsseitigen Halbröhrenteil **323**b, welches durchgängig mit der äußeren Führungsrille **310**b des Richtungswechseldurchlasses **310** verbunden ist, der wiederum an der seitlichen Deckplatte **340** angeformt ist. Das innere, umfangsseitige Halbröhrenteil **323**a weist einen inneren Rillenabschnitt **309**a von rechteckigem Querschnitt sowie Seitenkantenabschnitte **323**b auf, die sich in Längsrichtung entlang des inneren Rillenabschnittes **309**a erstrecken. Die sich in Längsrichtung erstreckenden Kantenabschnitte **323**c des inneren, umfangsseitigen Halbröhrenteils **323**a weisen dieselbe Weite auf wie der Flanschabschnitt **333** des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **322**.

Das äußere umfangsseitige Halbröhrenteil **323**b ist als ein geradliniges Teil ausgeformt, das denselben rechteckigen Querschnitt wie die äußere Führungsrille **310**b des Richtungswechseldurchlasses aufweist, welcher wiederum an der seitlichen Deckplatte **340** ausgebildet ist. Das äußere, umfangsseitige Halbröhrenteil **323**b weist einen äußeren Rillenabschnitt **309**b auf, der durchgängig mit der äußeren Führungsrille **310**b verbunden ist, sowie Seitenkantenabschnitte **323**d, die sich in Längsrichtung entlang des äußeren Rillenabschnittes **309**b erstrecken. Die Seitenkantenabschnitte **323**b sind an ihren äußeren Kanten mit ihren Vorsprüngen **323**e versehen, die in Kontakt mit den Seitenkantenabschnitten 323c des inneren, umfangsseitigen Halbröhrenteils **323**a gebracht werden, um die Führungsrille für den Gurtabschnitt **312** des Kugelkäfigs **312** zu bilden.

Das innere, umfangsseitige Halbröhrenteil **323**a der Röhre **323** aus Harz hat dieselbe Länge wie der Körper **313**, Das innere, umfangsseitige Halbröhrenteil **323**a ist derart positioniert, daß es mit der Endfläche des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **322** gebracht wird, der an der Seite des Körpers **313** angeordnet ist.

Das äußere, umfangsseitige Halbröhrenteil **323**b der Röhre **323** aus Harz ist andererseits um eine Länge, die der Dicke der ersten Endplattenabschnitte **330**, **330** des dünnen Plattenabschnittes **329** entspricht, länger als der Körper **313**, wobei die ersten Endplattenabschnitte **330**, **330** an den beiden Enden des Körpers **313** angeordnet sind. Die äußeren, umfangsseitigen Halbröhrenteile **323**b werden in die Einsetzöffnungen **334** der ersten Endplattenabschnitte **330**, **332** eingesetzt. Eine Lagebestimmung des äußeren, umfangsseitigen Halbröhrenteils **323**b in Längsrichtung findet dadurch statt, daß die beiden Enden des äußeren, umfangsseitigen Halbröhrenteils **323**b, die in die Einsetzöffnungen **334** eingesetzt sind, in Kontakt mit der Umfangskante des Endabschnittes der äußeren Führungsrillen **310**b des Richtungswechseldurchlasses gebracht werden, die an der seitlichen Deckplatte **340** ausgeformt sind. Die Vorsprünge **323**e, die an den beiden sich in Längsrichtung erstreckenden Seitenkanten **323** des äußeren, umfangsseitigen Halbröhrenteils **323**b ausgeformt sind, berühren die äußeren Kanten der zylindrischen Flanschabschnitte des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **322**, um so eine Führungsrille zu bilden, und das äußere, umfangsseitige Halbröhrenteil **323**b und das innere, umfangsseitige Halbröhrenteil **323**a können sich in der Einsetzöffnung **314** nicht drehen.

Die Röhren **323** aus Harz und die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **322** als die den Kugelrücklauf bildenden Abschnitte sind über die Einsetzöffnungen **334**, die an den ersten Endplattenabschnitten **330**, **330** des dünnen Plattenabschnittes **329** angeformt sind, genau positioniert und auf diese Weise kann ein korrekter Zusammenbau stattfinden.

Die seitliche Deckplatte **340** ist mit vier ausgesparten Abschnitten **341** versehen, an denen die äußeren Führungsrillen **310**b des Richtungswechseldurchlasses angeordnet sind, in die die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **322** eingepaßt werden, sowie Anschraubabschnitte, um die seitliche Deckplatte **340** am Körper **313** zu befestigen. An den Anschraubabschnitten wird die seitliche Deckplatte **340** am Körper **313** befestigt, in dem Schrauben **344** in an der seitlichen Deckplatte **340** ausgeformten Löcher **343** eingesetzt werden und die Schrauben **344** in die Gewindelöcher **345** eingreifen, die an der Endfläche des Körpers **313** ausgebildet sind. Die Öffnungen **343** sind zwischen den ersten Endplattenabschnitten **330**, **330** des dünnen Plattenabschnittes **329** angeordnet.

Der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **322** wird in den ausgesparten Abschnitt **341** der seitlichen Deckplatte **340** eingepaßt. Der dünne Plattenabschnitt **329** wird zwischen der seitlichen Deckplatte **340** und der Endfläche des Körpers **313** durch eine Klemmkraft fest gehalten, so daß er dazwischen befestigt ist.

Die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **322** und der den Kugeldurchlaß bildende Abschnitt **321** sind über den dünnen Plattenabschnitt **329** verbunden, wodurch es möglich wird, eine genaue Lagebeziehung des Endes der inneren Führungsrille **310**a des Richtungswechseldurchlasses relativ zu den den Kugeldurchlaß bildenden Abschnitten **321** sowie eine genaue Lagebeziehung der inneren Führungsrille **310**a des Richtungswechseldurchlasses relativ zum Kugelrücklauf **309** zu wahren.

Der dünne Plattenabschnitt **329** wird durch eine auf die seitliche Deckplatte **340** wirkende Klemmkraft gleichmäßig gegen die flache Endfläche des Körpers **313** gedrückt. Selbst wenn der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **322** sich nicht in einer korrekten Lage befindet, ändert der dünne Plattenabschnitt **329** seine Form, wodurch die korrekte Lage des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **322** ermöglicht wird. Der dünne Plattenabschnitt **329** wird durch eine Klemmkraft, die auf die seitliche Deckplatte **340** wirkt, festgeklemmt und befestigt und eine durch eine derartige Klemmung bewirkte Reibungskraft kann eine ungünstige Bewegung der inneren Führungsrille **310**a des Richtungswechseldurchlasses verhindern.

Entsprechend der vorliegenden Erfindung ist nur die Kugelgegenlaufrille **308** des Umlaufes **311** am Körper **313** mit hochfest ausgebildet und die anderen Abschnitte werden von den aus Harz geformten Körpern **320**, die den Kugelumlauf darstellen, gebildet. Eine präzise Bearbeitung nur der Kugelgegenlaufrille **308** des Körpers **313** ist ausreichend, wodurch die Anzahl der Arbeitsschritte und die Produktionskosten gesenkt werden kann.

Der aus Harz geformte Körper **320**, der den Kugelumlauf bildet, ist getrennt vom Körper **313** ausgebildet. Selbst wenn die äußere Hülse **304** größer ist, gibt es keine Beschränkung der Strömung des flüssigen Harzes durch den Körper **313**, in dem Fall, in dem der Körper **313** einstückig mit dem aus Harz geformten Körper **320** ausgebildet ist. Eine Erhöhung der Anzahl von Eingußstellen, die in einer Gußform ausgebildet sind, kann einen korrekten Fluß des flüssigen Harzes sicherstellen, wodurch die Formgebung verbessert wird. Insbesondere weisen die den Kugeldurchlaß bildenden Abschnitte **321**, **321**, die an den gegenüberliegenden, sich in

Längsrichtung erstreckenden Seiten der Kugellaufrille **308** angeordnet sind, eine niedrige Wandstärke auf, was zum Ergebnis hat, daß das flüssige Harz nicht jeden Teil des zur Ausbildung der den Kugeldurchlaß bildenden Abschnitt **321**, **321** vorgesehenen Raum erreichen kann. Daher ist es günstig, den aus Harz gebildeten Körper **320** getrennt vom Körper **313** entsprechend dem Ausführungsbeispiel der vorliegenden Erfindung auszubilden.

Die den Kugeldurchlaß bildenden Abschnitte **321**, **321** sind durchgängig und einstückig mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322** verbunden und die geteilten Teile sind derart ausgerichtet verbunden, daß eine Randverbindung entsteht. Es ist daher möglich, eine günstige Durchgängigkeit des Verbindungsabschnittes des Umlaufs zu erzielen und einen glatten Umlauf der Kugeln **303** vom Kugeldurchlaß zwischen der Kugellaufrille **305** und der Kugelgegenlaufrille **308** zum Richtungswechseldurchlaß **310** sowie vom Richtungswechseldurchlaß **310** zum Kugelrücklauf **309** zu ermöglichen.

Im folgenden werden Abänderungen des aus Harz gebildeten Körpers **320**, die einen Kugelumlauf bildet und der in Teile unterteilt ist, beschrieben. Bei der Beschreibung der Abänderungen werden abgeänderte Merkmale nur im Vergleich zum dritten Ausführungsbeispiel der vorliegenden Erfindung beschrieben. Dieselben Bauteile erhalten dieselben Bezugszeichen wie die des dritten Ausführungsbeispiels der vorliegenden Erfindung und auf ihre Beschreibung wird im folgenden verzichtet.

[Erste Abänderung]

Die **Fig.** 31 und 32 zeigen die erste Abänderung des aus Harz gebildeten Körpers **320**, der den beim dritten Ausführungsbeispiel beschriebenen Kugelumlauf bildet.

Bei der ersten Änderung besteht der aus Harz gebildete Körper **320**, der den Kugelumlauf bildet, aus einem ersten, aus Harz gebildeten Rahmen **320**A, der dadurch erhalten wird, daß die den Kugeldurchlaß bildenden Abschnitte **321**, **321** und die Röhren **323** aus Harz an der einen Seite an ihren Enden mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322**A verbunden werden, sowie aus einem zweiten, aus Harz gebildeten Rahmen **320**B, der mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322**B der anderen Seite versehen und getrennt vom ersten, aus Harz gebildeten Rahmen **320** ausgestaltet ist.

In diesem Fall sind die den Kugeldurchlaß bildenden Abschnitte **321**, **321** einstückig mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322**A über den dünnen Plattenabschnitt **329**A wie beim ersten Ausführungsbeispiel verbunden.

Die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **322**A sind ebenfalls einstückig mit den Röhren **323** aus Harz über den dünnen Plattenabschnitt **329**A verbunden. In diesem Fall ist die Röhre **323** aus Harz als ein einstückiger hülsenförmiger Körper ausgestaltet, obwohl die Halbröhrenteile beim dritten Ausführungsbeispiel verwendet werden. Entsprechend gibt es keine Einsetzöffnung **334** im dünnen Plattenabschnitt **329**A und der Kugelrücklauf **309** ist am dünnen Plattenabschnitt **329**A offengelegt.

Der erste, aus Harz gebildete Rahmen **320**A und der zweite, aus Harz gebildete Rahmen **320**B sind, wie in der **Fig.** 32 gezeigt, mittels einer Verbindung miteinander verbunden, die eine Kombination einer Aussparung und eines darin einzusetzenden Vorsprungs, wie beispielsweise eine Randverbindung, umfaßt. Beim dargestellten Beispiel ist ein ausgesparter Abschnitt **336** einer Schwalbenschwanznut im zweiten, aus Harz geformten Rahmen **320**B angeformt und ein Eingriffsvorsprung **335**, der in den ausgesparten Abschnitt **336** eingreift, ist andererseits in den den Kugeldurchlaß bildenden Abschnitten **321**, **321** ausgebildet.

In diesem Fall ist die Röhre **323** aus Harz des ersten, aus Harz geformten Rahmens **320**A in die Durchgangsöffnung **314** des Körpers **313** eingesetzt und die den Kugeldurchlaß bildenden Abschnitte **321**, **321** und der Verbindungsplattenabschnitt **236** sind entlang der Innenfläche der Aussparung **307** des Körpers **313** eingesetzt.

Dann werden die Eingriffsvorsprünge **335**, die an den jeweiligen freien Endabschnitten der den Kugeldurchlaß bildenden Abschnitte **321**, **321** und des Verbindungsplattenabschnittes **326** angeformt sind, mit den ausgesparten Abschnitten **336** in Eingriff gebracht, die am dünnen Plattenabschnitt **329**B des zweiten, aus Harz geformten Rahmens **324**B angeformt ist, welcher wiederum an der anderen Endfläche des Körpers **313** angeordnet ist.

Die ausgesparten Abschnitte **336** können am ersten, aus Harz geformten Rahmen **320**A und die Eingriffsvorsprünge **335** können am zweiten aus Harz geformten Rahmen **320**B angeformt sein. Die Verbindung ist nicht auf die oben beschriebene Verbindung beschränkt, sondern es kann jedwede herkömmliche Verbindung verwendet werden bei der die Enden der getrennten Teile in einer geeigneten Verbindungslage gehalten und verbunden werden können.

[Zweite Abänderung]

Die **Fig.** 33 und 34 zeigen die zweite Abänderung des aus Harz gebildeten Körpers **320**, der den Kugelumlauf bildet, wie er im dritten Ausführungsbeispiel beschrieben ist.

Bei der zweiten Abänderung ist der aus Harz gebildete Körper **320**, der den Kugelumlauf bildet und der durch einstückige Formgebung der den Kugeldurchlaß bildenden Abschnitte **321**, **321** und der Röhren **323** aus Harz als ein den Rücklauf bildender Abschnitt mit einem Paar von einen Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322**, **322** erhalten wurde, am Mittelabschnitt eines jeden, den Kugelrücklauf bildenden Abschnittes **321**, **321** und der den Kugelrücklauf bildenden Abschnitte **323** in zwei Teile geteilt. Insbesondere sind die den Kugeldurchlaß bildenden Abschnitte **321**, **321** und die den Kugelrücklauf bildenden Abschnitte **323** an ihrem Mittelabschnitt in die jeweiligen zwei Hälften geteilt und eine jede der derart getrennten Hälften ist einstückig mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322**, **322** ausgeformt, wodurch zwei aus Harz gebildete Rahmen **320**C, **320**D mit im wesentlichen der gleichen Form ausgebildet sind.

An den geteilten Enden der den Kugeldurchlaß bildenden Abschnitte **321**, **321**, den geteilten Enden des mittleren Verbindungsplattenabschnittes **326** und den geteilten Enden der Röhren **323** aus Harz sind ausgesparte Abschnitte **338** und darin einzusetzende Eingriffsvorsprünge **337** ausgebildet.

[Dritte Abänderung]

Fig. 35 zeigt die dritte Abänderung des aus Harz gebildeten Körpers **320**, der den Kugelumlauf bildet, wie er beim dritten Ausführungsbeispiel beschrieben ist.

Bei der dritten Abänderung wird die Röhre **323** aus Harz, die einen den Rücklauf bildenden Abschnitt darstellt, wie beim ersten Ausführungsbeispiel beschrieben, nicht verwendet, und ein aus Harz geformter Rahmen **320**E wird durch einstückige Formgebung der den Kugeldurchlaß bildenden Abschnitte **320**, der Verbindungsplattenabschnitte **326** mit den dünnen Plattenabschnitten **329**, **329** erhalten, die jeweils das Paar von den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322**, **322** aufweisen. Der Kugelrücklauf **309** ist als eine im Körper **313** ausgebildete Durchgangsöffnung ausgestaltet.

In diesem Fall kann am Öffnungsende der Kugelöffnung **339** des dünnen Plattenabschnittes **329** ein Eingriffsvorsprung **339**a ausgeformt sein, der mit einem sich verjüngenden Abschnitt **315** in Eingriff bringbar ist, der im Öffnungsende des Kugelrücklaufs **309** ausgestaltet ist. Ein derartiger Aufbau erlaubt es, eine günstige Verbindung des Endes des Kugelrücklaufs **309** und des den Richtungswechseldurchlaß und innere Führung bildenden Abschnitts **323** herzustellen.

Beim dargestellten Beispiel ist zusätzlich ein gebogener Eingriffsvorsprung **348** am Verbindungsabschnitt der äußeren Führungsrille **310**b ausgestaltet, die an der seitlichen Deckplatte **340** zusammen mit dem Kugelrücklauf **309** ausgebildet ist. Der Eingriffsvorsprung **348** kann in den dünnen Plattenabschnitt **329** eingreifen.

[Vierte Abänderung]

Fig. 36 zeigt die vierte Abänderung des aus Harz geformten Körpers **320**, der den Kugelumlauf bildet, wie er beim dritten Ausführungsbeispiel beschrieben ist.

Bei der vierten Abänderung wird die Röhre **323** aus Harz, wie sie bei der dritten Abänderung beschrieben ist, nicht verwendet und ein aus Harz gebildeter Rahmen **320**F wird durch einstückige Formgebung der den Kugeldurchlaß bildenden Abschnitte **321** mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322** an der einen Seite erhalten, der andere aus Harz geformte Rahmen **320**G, der mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **322** der anderen Seite versehen ist, ist vom oben erwähnten, aus Harz gebildeten Rahmen **320**F getrennt ausgebildet und die aus Harz geformten Rahmen **320**F, **320**G sind miteinander durch den Eingriff des Eingriffvorsprungs **335** in die Aussparung **336** verbunden. Der restliche Aufbau ist derselbe wie der der dritten Abänderung.

Beim oben beschriebenen dritten Ausführungsbeispiel werden drei aus Harz geformte Körper zur Bildung des Kugelumlaufs verwendet, von denen ein jeder in zwei Teile geteilt ist. Es können jedoch auch sechs aus Harz geformte Körper für die jeweiligen Umläufe verwendet werden. Es kann aber auch ein einzelner aus Harz geformter Körper verwendet werden. In diesem Fall sollte die Art der Teilung des aus Harz geformten Körpers auf den ersten, zweiten und vierten Abänderungen beruhen, wie sie oben beschrieben wurden, wobei die Schwierigkeit des Einsetzens des aus Harz geformten Körpers in den Körper der äußeren Hülse in Betracht gezogen werden sollte.

[Abänderungen der Kugellaufbahn]

Beim dritten Ausführungsbeispiel und bei dessen ersten bis vierten Abänderung ist die Kugelverzahnung von der Bauart einer Kugellaufbahn mit abgewinkelten Berührungslinien. Die vorliegende Erfindung kann jedoch auch bei einer Kugelverzahnung von der Bauart mit einer Kugellaufbahn mit radialen Berührungslinien verwendet werden, wie dies in der **Fig.** 37 gezeigt ist. Bei einer derartigen Kugellaufbahn mit einer radial verlaufenden Berührungslinie weist die Spurstange keinerlei Vorsprünge am äußeren Umfang auf, so daß ein kreisförmiger Querschnitt entsteht und die äußere Hülse hat am inneren Umfang keinerlei Aussparungen, so daß sie eine hohlzylindrische Form aufweist. Die Kugellaufbahn mit radialen Berührungslinien hat einen kleineren Kontaktwinkel -als die Kugellaufbahn von der Bauart mit winkelförmiger Kontaktlinie. Bezüglich der Art der Teilung des aus Harz geformten Körpers **320**, der den Kugelumlauf bildet, können sämtliche, beim dritten Ausführungsbeispiel und den ersten bis vierten Abänderungen beschriebenen Schemata verwendet werden.

Beim Beispiel, das in der **Fig.** 37 dargestellt ist, sind sechs aus Harz geformte Körner **320**, die den Kugelumlauf bilden, getrennt voneinander jeweils für die sechs Kugellaufbahnen vorgesehen. Die oben erwähnten zwei Bausätze der aus Harz geformten Körper **320** können einstückig miteinander ausgebildet sein, so daß sie drei Bausätze von aus Harz geformten Körper **320** bilden, die die sechs Kugelumläufe umfassen. Es kann aber auch der einzelne, aus Harz geformte Körper mit den sechs Kugelumläufen verwendet werden.

[Viertes Ausführungsbeispiel]

Die **Fig.** 38 und 39 stellen das vierte Ausführungsbeispiel dar. Beim vierten Ausführungsbeispiel wird die vorliegende Erfindung bei einer Rollenverzahnung verwendet bei der Rollen als Rollkörper verwendet werden.

Die in **Fig.** 38 gezeigte Rollenverzahnung **401** besteht aus einer Spurstange **402** als einem sich geradlinig erstreckenden Führungsteil und einer äußeren Hülse **404**, die derart angeordnet ist, daß sie entlang der Spurstange **402** über die Rollen **403** als Rollkörper beweglich ist.

Die Spurstange **402** ist in Form eines langen Balkens ausgebildet, der einen abgeänderten Querschnitt aufweist. Die Spurstange **402** weist an ihrem äußeren Umfang drei Vorsprünge **406** auf. An den beiden Seiten eines jeden Vorsprungs **406** sind zwei Rollenlaufflächen **405**, **405** angeordnet, so daß insgesamt sechs Laufflächen vorhanden sind.

Die äußere Hülse **404** weist an ihrem inneren Umfang drei Aussparungen **407** auf, die den Vorsprüngen **406** der Spurstange **402** jeweils entsprechen. An den beiden Ecken eines jeden Vorsprungs **407** sind Rollengegenlaufflächen **408**, **408** ausgebildet, die den oben erwähnten Rollenlaufflächen **405**, **405** entsprechen.

Zusätzlich weist die äußere Hülse **404** sechs Rollenrückläufe **409**, **409**; **409**, **409**; **409**, **409** auf, die parallel zu den sechs Rollengegenlaufflächen **408**, **408**; **408**, **408**; **408**, **408** und den sechs Richtungswechseldurchlässen **410**, **410**; **410**, **410**; **410**, **410** in Gestalt eines U-förmigen Rohres verlaufen, welches die Enden der oben erwähnten Rollengegenlaufflächen **408**, **408**; **408**, **408**; **408**, **408** mit den Enden der oben erwähnten Rollenrückläufe **409**, **409**; **409**, **409**; **409**, **409** verbindet. Die äußere Hülse **404** weist auf diese Weise sechs Umläufe auf.

Die Rollen **403**, die in einen jeden Umlauf eingesetzt sind, sind miteinander durch den gleichen Rollenkäfig **412** verbunden, wie der Rollenkäfig **212** der **Fig.** 19, so daß eine Kette von Rollen **403** gebildet wird. Die Rollen **403** werden durch den Rollenkäfig **412** geführt und laufen in einem jeden Umlauf um.

Die äußere Hülse **404** besteht aus einem hülsenförmigen Körper **413** mit den Rollengegenlaufflächen **408**, **408**; **408**, **408**; **408**, **408** drei aus Harz geformten Körpern **420**, **420**; **420**, die den Rollkörperumlauf bilden und in den Körper **413** eingesetzt sind, sowie ein Paar von seitlichen Deckplatten **440**, **440**, die an den beiden Enden des Körpers **413** nach dem Einsetzen der aus Harz geformten Körper **420**, **420**, **420** im Körper **413** befestigt werden.

Beim vierten Ausführungsbeispiel werden sechs Umläufe durch die drei aus Harz geformten Körper **420**, **420**, **420** wie beim dritten Ausführungsbeispiel gebildet.

Ein jeder der aus Harz gebildeten Körper **420**, die den Rollkörperumlauf bilden, weist ein Paar von den Rollendurchlaß bildenden Abschnitten **421**, **421** auf, die sich entlang der in Längsrichtung verlaufenden Seitenkanten der Rollengegenlaufflächen **408** erstrecken, sowie ein Paar von den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422**, **422**, die an den beiden Enden des Körpers **413** vorgesehen sind, sowie ferner Röhren **423** aus Harz als einen den Rücklauf bildenden Abschnitt, die in im Körper **413** ausgebildeten Durchgangsöffnungen eingesetzt sind.

Die den Rollendurchlaß bildenden Abschnitte **421**, **421** sind mit Führungsrillen versehen, die die beiden Seitenkanten des Gurtabschnittes **412**b des Rollenkäfigs **412** in einem belasteten Bereich führen. Die Führungsrillen können nicht nur verhindern, daß der Rollenkäfig **412** während des Umlaufs der Rollen schwingt, sondern auch, daß der Rollenkäfig **412** durchhängt, indem die Seitenkanten des Gurtabschnittes **412**b in die Führungsrille **421**a eingreifen, wenn die äußere Hülse **404** von der Spurstange **402** entfernt wird. Die Rollen **403** werden durch den Rollenkäfig **412** gehalten. Insbesondere wird der Rollenkäfig **412** durch einen Backenabschnitt der Führungsrille **421**a gehalten, was zum Ergebnis hat, daß die Rollkörper **403** in ihrer richtigen Lage gehalten werden und nicht aus der äußeren Hülse **404** herausfallen können.

Außerdem sind im Rollenrücklauf **409** und dem Richtungswechseldurchlaß **410** im Rollenrücklauf **409** und dem Richtungswechseldurchlaß **410** als nicht belasteten Bereichen Führungsrillen **409**c, **410**c ausgebildet, um die Seitenkanten des Gurtabschnittes **412**b zu führen. Die Führungsrillen **409**c, **410**c sind mit der oben erwähnten Führungsrille **421**a im belasteten Bereich verbunden, um so eine endlose Rille am gesamten Umfang zu bilden.

Wenn der Rollenkäfig **412** nicht verwendet wird, werden die Führungsrillen **421**a, **410**a, **409**a nicht benötigt und die in den **Fig.** 20(h) gezeigten Backenabschnitte zum Abstützen der Rollenenden sind in den den Rollendurchlaß bildenden Abschnitten **421** ausgebildet.

In jedem der aus Harz gebildeten Körner **420**, die den Rollenumlauf bilden, sind zumindest vier Verbindungsabschnitte der den Rollendurchlaß bildenden Abschnitte **421**, **421** mit dem Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422**, **422** miteinander einstückig verbunden. Der aus Harz geformte Körper **420** ist an den anderen Abschnitten in einzelne Teile geteilt, so daß er in den Körper **413** eingesetztwerden kann.

Das grundsätzliche Ausführungsbeispiel des aus Harz gebildeten Körpers, der den Rollenumlauf bildet, der bei der keilverzahnten Vorrichtung verwendet wird, ist im Detail im dritten Ausführungsbeispiel beschrieben. Der Aufbau des aus Harz geformten Körpers, der den Rollenumlauf bildet, ist genauer beim zweiten Ausführungsbeispiel beschrieben. An dieser Stelle wird nur das grundsätzliche Teilungsschema des aus Harz gebildeten Körpers **420**, der den Rollenumlauf bildet, unter Bezugnahme auf die **Fig.** 39 im folgenden kurz beschrieben.

In der **Fig.** 39(a) sind die beiden Bausätze der den Rollendurchlaß bildenden Abschnitte **421**, **421** mit dem jeweiligen einen Ende des Paars der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **422**, **422** einstückig verbunden, um einen einzelnen Rahmen **424** aus Harz zu bilden, und die beiden Enden eines jeden der den Rücklauf bildenden Abschnitte **423** sind nicht mit dem anderen Ende des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **422** verbunden, so daß diese Teile in den Körper **418** eingebaut werden können.

In der **Fig.** 39(b) besteht der aus Harz geformte Körper **420**, der den Rollenumlauf bildet, aus dem ersten, aus Harz gebildeten Rahmen **420**A, der durch einstückige Verbindung der den Rollendurchlaß bildenden Abschnitte **421**, **421** und der Röhren **423** aus Harz als einen Rücklauf bildenden Abschnitt an deren Enden mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422**A an der einen Seite gebildet ist, und aus dem zweiten, aus Harz gebildeten Rahmen **420**B, der mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422**B an der anderen Seite versehen und getrennt vom ersten aus Harz geformten Rahmen **420**A ausgebildet ist.

In der **Fig.** 39(c) ist der aus Harz gebildete Körper **420**, der den Rollenumlauf bildet, der durch einstückige Verbindung der den Rollendurchlaß bildenden Abschnitte **421**, **421** und den Röhren **423** aus Harz als einen Rücklauf bildenden Abschnitt mit einem Paar von einen Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422**, **422** erhalten wird, am Mittelabschnitt eines jeden einen Rollendurchlaß bildenden Abschnittes **421**, **421** und an dem den Rollenrücklauf bildenden Abschnitten **423** in zwei Teile geteilt. Insbesondere sind die den Rollenrücklauf bildenden Abschnitte **421**, **421** und die Röhren **423** aus Harz an ihrem Mittelabschnitt in jeweils zwei Hälften geteilt und eine jede der derartig geteilten zwei Hälften ist einstückig mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422**, **422** ausgebildet, wodurch zwei aus Harz geformte Rahmen **420**C, **420**D mit im wesentlichen derselben Form gebildet werden.

In **Fig.** 39(d) wird die in der **Fig.** 39(a) gezeigte Röhre **423** aus Harz nicht verwendet und ein aus Harz geformter Rahmen **420**E wird durch einstückige Formgebung der den Rollendurchlaß bildenden Abschnitte und dem Verbindungsplattenabschnitt **326** zusammen mit den dünnen Plattenabschnitten **429**, **429** erhalten, von denen ein jeder das Paar von den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422**, **422** aufweist. Der Rollenrücklauf **409** wird von einer im Körper **413** angeformten Durchgangsöffnung gebildet.

In der **Fig.** 39(e) wird die in der **Fig.** 39(b) verwendete Röhre **423** aus Harz nicht verwendet und ein aus Harz gebildeter Rahmen **420**F wird durch einstückige Formgebung der den Rollendurchlaß bildenden Abschnitte **421** zusammen mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422** an der einen Seite erhalten, der andere aus Harz geformte Rahmen **420**G, der mit den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **422** an der anderen Seite versehen ist, ist getrennt vom oben erwähnten, aus Harz geformten Rahmen **420**F gebildet.

In den **Fig.** 39(a) bis 39(e) sind die aus Harz geformten Rahmen miteinander mittels einer herkömmlichen Verbindung, wie beispielsweise eine Randverbindung, miteinander verbunden, welche durch den Eingriff eines Eingriffsvorsprungs in eine Aussparung zustande kommt.

[Fünftes Ausführungsbeispiel]

Die **Fig.** 40 bis 44 zeigen eine Führungsvorrichtung für eine geradlinige Bewegung gemäß dem fünften Ausführungsbeispiel der vorliegenden Erfindung.

Die Führungsvorrichtung **501** für eine geradlinige Bewegung ist mit einer Führungsschiene **502** als einem Führungsteil versehen, welche sich geradlinig erstreckt, und weist einen beweglichen Block **504** als ein bewegliches Teil auf, das derart angeordnet ist, daß es entlang der Führungsschiene **502** über eine große Anzahl von Kugeln **503** als Rollenkörper beweglich ist.

Die Führungsschiene **502** hat die Form eines langen Balkens mit rechteckigem Querschnitt. Zwei Kugellaufrillen **505**, **505** als Rollkörperlaufbahnen sind an den rechten und linken Seitenflächen der Führungsschiene **502** angeformt, so daß insgesamt vier Rillen **505** vorgesehen sind. Die Führungsschiene **502** weist an einer jeden Seitenfläche einen Vorsprung **502**a auf, an dessen oberen und unteren Stellen die Kugellaufrillen **505**, **505** angeordnet sind.

Der bewegliche Block **504** ist als ein Blockkörper mit einem Querschnitt in Form eines umgedrehten U's ausgebildet, dessen Öffnungsende nach unten gerichtet ist. Der Blockkörper ist mit einem waagerechten Abschnitt **506** versehen, der der Oberfläche der Führungsschiene **502** gegenüberliegt, sowie mit einem Paar von Schenkelabschnitten **507**, **507**, die sich von den rechten und linken Enden des waagerechten Abschnittes **506** nach unten erstrecken und den rechten und linken Seitenflächen der Führungsschiene **502** jeweils gegenüberliegen. Ein jeder der Schenkelabschnitte **507**, **507** weist an seiner Innenfläche zwei Kugelgegenlaufrillen **508**, **508** als Rollkörpergegenlaufbahnen auf, die den jeweiligen Kugellaufrillen **505**, **505** entsprechen, die an den rechten und linken Seitenflächen der Führungsschiene **502** ausgebildet sind.

Ein jeder der rechten und linken Schenkelabschnitte **507**, **507** des beweglichen Blocks **504** weist zwei Kugelrückläufe bildende Abschnitte **509**, **509** auf, die darin ausgeformt sind und sich parallel zu den Kugelgegenlaufrillen **508**, **508** erstrecken. An den beiden in Längsrichtung liegenden Enden eines jeden Schenkelabschnittes **507**, **507** sind Richtungswechseldurchlässe **510**, **510**; **510**, **510** angeordnet, die die Enden der Kugelgegenlaufrillen **508**, **508**; **508**, **508** mit den Enden der Kugelrückläufe **509**, **509**; **509**, **509** verbinden. Alles in allem weist ein jeder der Schenkelabschnitte **507**, **507** des beweglichen Blocks **504** zwei endlose Umläufe auf, in denen die Kugeln **503** umlaufen, um so insgesamt vier Umläufe vorzusehen.

In einem jeden der vier endlosen Umläufe dieses Ausführungsbeispiels sind die Kugeln **503** kettenartig durch einen Kugelkäfig **512** als Rollkörperkäfig gehalten, so daß die Kugeln **503** umlaufen können, während sie vom Kugelkäfig **512** geführt werden.

Wie in den **Fig.** 44(c) bis 44(e) gezeigt ist, weist der Kugelkäfig **512** einen flexiblen Gurtabschnitt **512**b auf, der mit Kugelöffnungen **512**e zur jeweiligen Aufnahme der Kugel **503** sowie mit Abstandsabschnitten **512**c versehen ist, die zwischen zwei aufeinanderfolgenden Kugeln **503**, **503** angeordnet sind. Der Gurtabschnitt **512**b hat eine größere Weite als der Durchmesser einer Kugel **503**, so daß die beiden Seitenkanten des Gurtabschnittes **512**b sich von einer Kugel **503** nach außen erstrecken.

Der Abstandsabschnitt **512**c ist mit einer eine Kugel abstützenden, kugelförmigen Aussparung **512**d versehen, die der kugelförmigen Oberfläche einer Kugel **503** entspricht. Eine Kugel **503** wird an ihren beiden Seiten durch ein Paar von stützenden, kugelförmigen Aussparungen **512**d gehalten, so daß verhindert wird, daß eine Kugel **503** vom Gurtabschnitt **512**b herausfallen kann. Bei diesem Ausführungsbeispiel ist das eine Ende des Gurtabschnitts **512**b nicht mit dessen anderen Ende verbunden, wodurch ein streifenförmiger Gurt mit zwei Enden entsteht. Das eine Ende des Gurtabschnitts **512**b kann mit dessen anderem Ende verbunden sein, so daß ein endloser Gurt entsteht.

Wie in der **Fig.** 41 gezeigt ist, besteht der bewegliche Block **504** aus einem Blockkörper **513** mit Kugelgegenlaufrillen **508**, **508**, **508**, **508**, einem Paar von rechten und linken, aus Harz gebildeten Körpern **520**, **520**, die den Kugelumlauf bilden, der in den Blockkörper **513** eingesetzt ist, und einem Paar von seitlichen Deckplatten **540** (nur eine Deckplatte **540** ist gezeigt), die an den beiden Endflächen des Blockkörpers **513** befestigt sind, in den die aus Harz geformten Körper **520**, **520** eingesetzt sind.

Bei einem jeden der rechten und linken aus Harz geformten Körper **520**, **520**, die den Kugelumlauf bilden, sind zwei endlose Umläufe ausgebildet. Die rechten und linken aus Harz geformten Körper **520**, **520** sind symmetrisch. Einer dieser beiden Körper wird im folgenden beschrieben, auf die Beschreibung des anderen Körpers wird verzichtet.

Insbesondere besteht der aus Harz geformte Körper **520**, der den Kugelumlauf bildet, aus einem Rahmen **524** aus Harz, der durch einstückige Formgebung der den Kugelumlauf bildenden Abschnitte **521**, **521**, die sich entlang der beiden, in Längsrichtung erstreckenden Seiten der Kugelgegenlaufrille **508** erstrecken, mit dem Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522**, **522** (vgl. **Fig.** 42) sowie einem Paar von Röhren **523**, **523** aus Harz erhalten wird, die einen den Rücklauf bildenden Abschnitt darstellen und in Durchgangsöffnungen **514**, **514** eingesetzt sind, die im Blockkörper **513** (vgl. **Fig.** 43) gebildet sind. Die den Kugeldurchlaß bildenden Abschnitte **521**, **521** sind mit dem Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522**, **522** einstückig ausgebildet, um den Rahmen **524** aus Harz als einen einstückigen Körper zu bilden, und das Paar der Röhren **523**, **523** aus Harz ist getrennt von diesem einstückigen Körper ausgebildet, so daß diese Teile als Blockkörper **513** zusammengebaut werden können.

Wie in der **Fig.** 42 gezeigt ist, sind die den Kugeldurchlaß bildenden Abschnitte **521**, **521** mit Führungsrillen zum Führen der beiden Seitenkanten des Gurtabschnittes **512**b des Kugelkäfigs **512** in einem belasteten Bereich versehen. Diese Führungsrillen können nicht nur verhindern, daß der Kugelkäfig während des Umlaufs der Kugeln schwingt, sondern auch daß er durchhängt, indem die Seitenkanten des Gurtabschnittes **512**b in die Führungsrille **521**e eingreifen, wenn der bewegliche Block **504** von der Führungsschiene **502** entfernt wird. Die Kugeln **503** werden vom Kugelkäfig **512** gehalten. Insbesondere wird der Kugelkäfig **512** durch einen Backenabschnitt der Führungsrille **521**a abgestützt, was zur Folge hat, daß die Kugeln **503** in ihrer korrekten Lage gehalten werden und nicht aus dem beweglichen Block **504** herausfahren können.

Der Abstand zwischen dem Paar der den Kugeldurchlaß bildenden Abschnitte **521**, **521**, die parallel zueinander an den beiden in Längsrichtung verlaufenden Seiten der Kugelgegenlaufrille **508** angeordnet sind, ist etwas kleiner als der Durchmesser einer Kugel **503**. Bei einem derartigen Aufbau ist es möglich zu verhindern, daß die Kugeln **503** aus den den Kugeldurchlaß bildenden Abschnitten **521**, **521** herausfallen, selbst wenn der Kugelkäfig **512** nicht verwendet wird.

Außerdem sind beim Kugelrücklauf **509**, **509** und dem Richtungswechseldurchlässen **510**, **510** als nicht belasteten Bereichen Führungsrillen **509**c, **510**c ausgebildet, wie n den **Fig.** 44(a) und 44(b) gezeigt ist, um die Seitenkanten des Gurtabschnittes **512**(b) zu führen. Die Führungsrillen **509**(c), 510(c) sind mit der oben erwähnten Führungsrille **521**(a) im belasteten Bereich verbunden, um so eine endlose Rille am gesamten Umfang zu bilden.

Die den Kugeldurchlaß bildenden Abschnitte **521**, **521**; **521**, **521** sind, wie in der **Fig.** 42(a) gezeigt ist, aus dem ersten Verbindungsplattenabschnitt **525**, der sich in Längsrichtung entlang der Kante zwischen dem waagerechten Abschnitt **506** und dem Schenkelabschnitt **507** des Blockkörpers **513** in Längsrichtung des Blockkörpers **513** erstreckt, dem zweiten Verbindungsplattenabschnitt **526**, der sich in Längsrichtung zwischen der Kugelgegenlaufrille **508**, **508** an der Innenfläche eines jeden Schenkelabschnittes **507** des Blockes **513** erstreckt, und aus einem Paar von dritten Verbindungsplattenabschnitten **527** gebildet, die sich entlang der Unterfläche des Schenkelabschnitts **507** des Blockkörpers **513** in dessen Längsrichtung erstrecken.

Die obere Kante des ersten Verbindungsplattenabschnittes **525** und die untere Kante des zweiten Verbindungsabschnittes **526**, die einander gegenüberliegen, sind an den entgegengesetzten der oberen Kugelgegenlaufrille **508** plaziert, die im Schenkelabschnitt **507** angeordnet ist, um so die den Kugeldurchlaß bildenden Abschnitte **521**, **521** zu bilden. Die Unterkante des zweiten Verbindungsplattenabschnittes **526** und die Oberkante des dritten Verbindungsplattenabschnittes **527**, die einander gegenüberliegen, sind an entgegengesetzten Längsseiten der unteren Kugelgegenlaufrille **508** angeordnet, die im Schenkelabschnitt **507** vorgesehen ist, um so die den Kugeldurchlaß bildenden Abschnitte **521**, **521** zu bilden.

Wie in den **Fig.** 44(a), 44(b) und 44(c) gezeigt ist, sind die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522** und die den Kugeldurchlaß bildenden Abschnitte **521**, **521** durch den dünnen Plattenabschnitt **529** durch einstückige Formgebung miteinander verbunden. Die Röhre **523** aus Harz ist in eine Öffnung **534** eingesetzt, die im dünnen Plattenabschnitt **529** ausgeformt ist, um so eine Randverbindung herzustellen, und am dünnen Plattenabschnitt **529** befestigt.

Der dünne Plattenabschnitt **529** weist die den Richtungswechseldurchlaß und innere Führung bildende Abschnitte **522**, **522** auf, die derart ausgestaltet sind, daß sie entsprechend den zwei Kugellaufbahnen **503**, **503** an der Seitenfläche der Führungsschiene **502** hervorstehen. Die beiden Enden der ersten, zweiten und dritten Verbindungsplattenabschnitte **525–527** sind mit dem dünnen Plattenabschnitt **529** verbunden, um am Ende des Blockkörpers **513** angeordnet zu sein und so den einen Rahmen **524** aus Harz zu bilden.

Ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522** ist von halbzylindrischer Gestalt. Am äußeren Umfang der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522** ist eine innere Führungsrille **510**a mit halbkreisförmigem Querschnitt ausgeformt, um so den inneren Führungsabschnitt des Richtungswechseldurchlasses **510** zu bilden. Das eine Ende der inneren Führungsrille **510**a ist mit dem Ende der Kugelgegenlaufrille **508** verbunden. Dementsprechend weist das eine Ende der inneren Führungsrille **510**a denselben Querschnitt auf wie die Kugelgegenlaufrille **508**, um auf diese Weise das eine Ende der inneren Führungsrille **510**a mit dem Ende der Kugelgegenlaufrille **508** auszurichten. Das andere Ende der inneren Führungsrille **510**a des Richtungswechseldurchlasses **510** ist mit dem Ende des Kugelrücklaufes **509** verbunden. Dementsprechend weist das andere Ende der inneren Führungsrille **510**a denselben Querschnitt auf, wie der Kugelrücklauf **509**, um auf diese Weise das andere Ende der inneren Führungsrille **510**a mit dem Ende des Kugelrücklaufes **509** auszurichten.

Zylinderförmige Flanschabschnitte **533**, **533** sind an den beiden Enden der inneren Führungsrille **510**a ausgestaltet. Der Abstand zwischen den jeweiligen äußeren Flächen der zylindrischen Flanschabschnitte **533**, **533** ist größer als die Weite des Gurtabschnittes **512**b. Die zylindrischen Flanschabschnitte **533**, **533** bilden eine Käfigführungsrille **510**c für den Kugelkäfig **512** zusammen mit einem halbkreisförmigen, ausgesparten Abschnitt mit Aussparungen, der am inneren Umfang der Aussparung der seitlichen Deckplatte **540**, die weiter unten beschrieben ist, ausgebildet ist.

Die beiden Enden der inneren Führungsrille **510**a des Richtungswechseldurchlasses **510** erstrecken sich bis zur Kontaktfläche des dünnen Plattenabschnittes **529** mit der Endfläche des Blockkörpers **513**, um auf diese Weise mit den jeweiligen Enden der Kugelgegenlaufrille **508** und dem Kugelrücklauf **509** verbunden zu sein. Einsetzlöcher **534**, **534** für eine Röhre mit halbkreisförmigem Querschnitt, in welche die Enden der Röhren **523** aus Harz eingesetzt sind, sind am dünnen Plattenabschnitt **529** ausgeformt.

Wie in der **Fig.** 43 gezeigt ist, besteht die Röhre **523** aus einem äußeren umfangsseitigen Halbröhrenteil **523**b, das an der äußeren Umfangsseite des Kugelumlaufs angeordnet ist und durchgängig mit der äußeren Führungsrille **510**b des Richtungswechseldurchlasses **510** der seitlichen Deckplatte **540** verbunden ist, sowie aus einem inneren umfangsseitigen Halbröhrenteil **523**a, das an der inneren Umfangsseite des Kugelumlaufes angeordnet ist, der durchgängig mit einer inneren Führungsrille **510**a des Richtungswechseldurchlasses **510** der seitlichen Deckplatte **540** verbunden ist.

Das innere, umfangsseitige Halbröhrenteil **523**a weist einen Rillenabschnitt **509**a von halbkreisförmigem Querschnitt auf sowie Seitenkantenabschnitte **523**c, die sich in Längsrichtung entlang des Rillenabschnittes **509**a erstrekken, wie in den **Fig.** 43c und 43d gezeigt ist. Das äußere umfangsseitige Halbrillenteil **523**b ist als ein geradliniges Bauteil ausgebildet, das denselben kreisförmigen Querschnitt wie die äußere Führungsrille **510**b des Richtungswechseldurchlasses aufweist, der an der seitlichen Deckplatte **540** ausgebildet ist. Das äußere umfangsseitige Halbröhrenteil **523**b weist einen Rillenabschnitt **509**b auf, der durchgängig mit der äußeren Führungsrille **510**b verbunden ist, sowie Seitenkantenabschnitte **523**d, die sich in Längsrichtung entlang des Rillenabschnittes **509**b erstrecken. Die Seitenkantenabschnitte **523**d sind an ihren äußeren Kanten mit Vorsprüngen **523**e versehen, die in Kontakt mit den äußeren Kanten der Seitenkantenabschnitte **523**c des inneren umfangsseitigen Halbröhrenteils **523**a gebrachtwerden, um die Käfigführungsrille **509**d des Kugelkäfigs **512** zu bilden.

Das innere umfangsseitige Halbröhrenteil **523**a der Röhre **523** aus Harz weist dieselbe Länge wie der Blockkörper **513** auf. Das innere umfangsseitige Halbröhrenteil **523**a ist derart angeordnet, daß es in Kontakt mit der rückwärtigen Fläche des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **522** gebracht werden kann.

Das äußere umfangsseitige Halbröhrenteil **523**b der Röhre **523** aus Harz weist andererseits eine um die Dicke des dünnen Plattenabschnitts **529** größere Länge als der Blockkörper **513** auf. Die äußeren umfangsseitigen Halbröhrenteile **523**b werden in die Einsetzlöcher **534** eingesetzt. Eine Lagebestimmung des äußeren umfangsseitigen Halbröhrenteils **523**b findet in Längsrichtung dadurch statt, daß die beiden Enden des äußeren umfangsseitigen Halbröhrenteils **523**b, die in die Einsetzlöcher **534** eingesetzt sind, in Kontakt mit der in Umfangsrichtung verlaufenden Kante des Endabschnittes der äußeren Führungsrillen **510**b des Richtungswechseldurchlasses gebracht werden, die an der seitlichen Deckplatte **540** ausgeformt sind. Die an den beiden Seitenkanten des äußeren umfangsseitigen Halbröhrenteils **523**b angeformten Vorsprünge **523**e berühren die Außenkanten der zylindrischen Flanschabschnitte **533**, die an den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt **522** angeformt sind, um einen Teil der Führungsrille **510**c zu bilden, und das äußere umfangsseitigen Halbröhrenteil **523**b und das innere umfangsseitigen Halbröhrenteil **523**a können sich in der Einsetzöffnung **514** nicht drehen.

Die Röhren **523** aus Harz und die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522** werden über die am dünnen Plattenabschnitt **529** ausgebildeten Einsetzlöcher **534** genau positioniert, so daß auf diese Weise ein korrekter Zusammenbau stattfinden kann.

Wie in den **Fig.** 44(f) und 44(g) gezeigt ist, ist die seitliche Deckplatte **540** mit einem ausgesparten Einsetzabschnitt **540**a versehen, in den der dünne Plattenabschnitt **529** eingesetzt wird, sowie mit ausgesparten Abschnitten **541**, die die äußeren Führungsrillen **510**b des Richtungswechseldurchlasses aufweisen, in die die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522** eingepaßt werden, sowie ferner mit Abschnitten zur Befestigung von Schrauben, um die seitliche Deckplatte **540** am Blockkörper **513** zu befestigen. An den Abschnitten zum Befestigen von Schrauben wird die seitliche Deckplatte **540** am Blockkörper **513** befestigt, indem Schrauben (nicht gezeigt) in an der seitlichen Deckplatte **540** ausgebildete Öffnungen **543** eingesetzt werden und in Gewindelöcher **544**, die an der Endfläche des Blockkörpers **513** ausgeformt sind, eingreifen. Die Öffnungen **543** sind an vier Positionen angeordnet, d. h. der Position, die dem dünnen Plattenabschnitt **529** zwischen den den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten **522**, **522** eines jeden aus Harz gebildeten Körpers **520**, **520** entspricht und den Positionen in der Umgebung der dünnen Plattenabschnitte **529**, **529** am waagerechten Abschnitt **506**.

Wie in der **Fig.** 44(g) gezeigt ist, weist die äußere Führungsrille **510**b des Richtungswechseldurchlasses im ausgesparten Abschnitt **541** an ihren Seitenkanten gebogene Aussparungen **546** von einem größeren Durchmesser auf, die zusammen mit den zylindrischen Flanschabschnitten **533** der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522**, wie in der **Fig.** 44(f) gezeigt, die Käfigführungsrille **510**c bilden, sowie bogenförmige Aussparungen **547** von kleinerem Durchmesser, in die die zylindrischen Flanschabschnitte **533** eingesetzt werden. Der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **522**, der mit der inneren Führungsrille **510**a des Richtungswechseldurchlasses versehen ist, ist in den ausgesparten Abschnitt **541** der seitlichen Deckplatte **540** eingepaßt und der dünne Plattenabschnitt **529** wird im ausgesparten Einsetzabschnitt **540**a der seitlichen Deckplatte **540** aufgenommen. Der dünne Plattenabschnitt **529** ist zwischen der seitlichen Deckplatte **540** und der Endfläche des Blockkörpers **513** durch eine Klemmkraft gehalten, so daß er fest dazwischen befestigt ist.

Die den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522** und der den Kugeldurchlaß bildende Abschnitt **521** sind über den dünnen Plattenabschnitt **529** verbunden, wodurch es möglich ist, eine genaue Lagebeziehung des Endes der inneren Führungsrille **510**a des in dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt **522** ausgebildeten Richtungswechseldurchlaß relativ zu den den Kugeldurchlaß bildenden Abschnitten **521**, **521** als auch eine genaue Lagebeziehung der inneren Führungsrille **510**a des Richtungswechseldurchlasses relativ zum Kugelrücklauf **509**.

Der dünne Plattenabschnitt **529**, der in der Umgebung des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **522** angeordnet ist, wird gleichmäßig gegen die flache Endfläche des Blockkörpers **513** durch eine auf die seitliche Deckplatte **540** wirkende Klemmkraft gedrückt (vgl. **Fig.** 44). Selbst wenn der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **522** sich nicht in einer korrekten Lage befindet, ändert der dünne Plattenabschnitt **529** seine Form an der Endfläche des Blockkörpers **513**, wodurch die korrekte Positionierung des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes **522** ermöglicht wird. Der dünne Plattenabschnitt **529** wird durch eine Klemmkraft, die auf die seitliche Deckplatte **540** wirkt, festgeklemmt und befestigt und eine durch eine derartige Klemmung erzeugte Reibkraft kann eine ungünstige Bewegung der inneren Führungsrille **510**a des Richtungswechseldurchlasses verhindern.

Die seitliche Deckplatte **540** ist am Blockkörper **513** befestigt, so daß der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **522**, der am Blockkörper **513** angebaut ist, in den ausgesparten Abschnitt **541** der seitlichen Deckplatte **540** eingepaßt wird. Ein derartiges Einpassen ermöglicht eine genaue Positionierung der seitlichen Deckplatte **540** relativ zum Blockkörper **513**.

Im folgenden werden die Schritte zum Zusammenbau der oben erwähnten, aus Harz gebildeten Körper **520**, die den Kugelumlauf bilden, beschrieben.

Zunächst wird das innere umfangsseitige Halbröhrenteil **523**a der Röhre **523** aus Harz in die Durchgangsöffnung **514** des Schenkelabschnittes **507** des Blockkörpers **513** eingesetzt.

Dann wird der durch einstückige Formgebung erhaltene Rahmen **524** aus Harz in die Aussparung des Blockkörpers **513** eingesetzt, wodurch die dünnen Plattenabschnitte **529** an den beiden Enden des Rahmens **524** aus Harz an den jeweiligen Endflächen des Schenkelabschnittes **507** des Blockkörpers **513** entlanggleiten. Der erste Verbindungsplattenabschnitt **525** des Rahmens **524** aus Harz berührt den Eckenabschnitt zwischen dem waagerechten Abschnitt **506** und dem Schenkelabschnitt **507**, wodurch eine Lagebestimmung in senkrechter Richtung des Rahmens **524** aus Harz stattfindet. Der zweite Verbindungsplattenabschnitt **526** und der dritte Verbindungsplattenabschnitt **527** des Rahmens **524** aus Harz berühren die jeweiligen Innenflächen der Schenkelabschnitte **507** des Blockkörpers **513**, wodurch eine Lagebestimmung der den Kugeldurchlaß bildenden Abschnitte **521**, **521** und der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte **522**, **522** stattfindet. Zu diesem Zeitpunkt sind die Einsetzlöcher **534**, **534** des dünnen Plattenabschnittes **529** mit den Durchgangsöffnungen **514**, **514** des Blockkörpers **513** ausgerichtet.

Dann werden die äußeren umfangsseitigen Halbröhrenteile **523**b, **523**b in die Durchgangsöffnungen **514**, **514** von den Einsetzöffnungen **534**, **534** aus eingesetzt, wodurch der Zusammenbau einer der aus Harz geformten Körper **520**, **520**, die den Kugelumlauf bilden, fertiggestellt ist.

Der Zusammenbau des anderen aus Harz gebildeten Körpers **520**, **520** wird auf dieselbe Weise durchgeführt.

Dann wird die eine seitliche Deckplatte **540** an der einen Endfläche des Blockkörpers **513** durch Klemmen befestigt, der die Kugeln haltende Kugelkäfig **512** wird eingesetzt und die andere seitliche Deckplatte **540** wird an der anderen Endfläche des Blockkörpers **513** durch denselben Klemmvorgang befestigt, wodurch der Zusammenbau des beweglichen Blockes **504** fertig ist.

Entsprechend der vorliegenden Erfindung sind die aus Harz gebildeten Körper **520**, **520**, die den Kugelumlauf bilden, getrennt vom Blockkörper **513** ausgebildet. Selbst wenn der bewegliche Block **504** größer ist, gibt es keine Einschränkung des Flusses des flüssigen Harzes durch den Blockkörper **513** wie im Fall, in dem der Blockkörper **513** einstückig mit den aus Harz gebildeten Körpern **520**, **520** ausgebildet ist. Durch eine Erhöhung der Anzahl von Eingußstellen, die an einer Gußform ausgebildet sind, kann das korrekte Fließen des flüssigen Harzes sichergestellt werden und die Formgebung verbessert werden. Insbesondere sind die den Kugeldurchlaß bildenden Abschnitte **521**, **521**, die an den gegenüberliegenden Längsseiten der Kugelführungsrille **508** angeordnet sind, dünn, was zum Ergebnis hat, daß das flüssige Harz nicht jeden Teil des Raums erreichen kann, der die den Kugeldurchlaß bildenden Abschnitte **521**, **521** ausmacht. Daher ist es von Vorteil, die aus Harz gebildeten Körper **520**, **520** in Übereinstimmung mit dem Ausführungsbeispiel der vorliegenden Erfindung getrennt vom Blockkörper **513** auszubilden.

Da außerdem rechte und linke aus Harz gebildete Körper

520, **520**, die den Kugelumlauf bilden, ausgebildet sind, die jeweils Zwei endlose Umläufe aufweisen, kann ein korrektes Fließen des flüssigen Harzes selbst dann sichergestellt werden, wenn der bewegliche Block **513** relativ groß ist.

Der durchgängige Umlauf wird durch den aus Harz gebildeten Körper **520** gebildet und daher ist es möglich, eine Lagebestimmung der inneren Führungsrille **510**a des Richtungswechseldurchlasses relativ zu den den Kugeldurchlaß bildenden Abschnitten **521**, **521** sowie eine Lagebestimmung der inneren Führungsrille **510**a des Richtungswechseldurchlasses relativ zum Kugelrücklauf **509** durchzuführen, wodurch die Durchgängigkeit des Umlaufs sichergestellt wird, und ein glatter Umlauf der Kugeln **503** stattfinden kann.

Wenn die korrekte Lagebeziehung der inneren Führungsrille **510**a des Richtungswechseldurchlasses relativ zu den den Kugeldurchlaß bildenden Abschnitten **521**, **521** gewahrt ist, sind die den Kugeldurchlaß bildenden Abschnitte **521**, **521** an den beiden Längsseiten der Kugellaufrille **508** angeordnet und mit den Enden der inneren Führungsrille **510**a des Richtungswechseldurchlasses ausgerichtet.

Wenn die geeignete Lagebeziehung der inneren Führungsrille **510**a des Richtungswechseldurchlasses relativ zum Kugelrücklauf **509** gewahrt ist, kann die innere Führungsrille **510**a des Richtungswechseldurchlasses mit der inneren Rille **523**a des Kugelrücklaufs **509** ausgerichtet werden.

Der Verbindungsabschnitt der den Kugeldurchlaß bildenden Abschnitte **521**, **521** und der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt **522** werden durch einstückige Formgebung erhalten, wodurch auf einen Arbeitsschritt verzichtet werden kann, in dem der Verbindungsabschnitt zusammengebaut wird. Obwohl die Laufrichtung der Kugeln **503** in einem derartigen Verbindungsabschnitt sich ändert, kann der oben erwähnte einteilige Aufbau die Durchgängigkeit des Umlaufs sicherstellen, ohne daß er durch die Genauigkeit des Zusammenbaus beeinflußt wird. Daher ist ein glatter Umlauf der Kugeln **503** vom Kugelrücklauf zum Richtungswechseldurchlaß **510** zwischen der Kugellaufrille **505** und der Kugelgegenlaufrille **508** sowie vom Richtungswechseldurchlaß **510** zum Kugelrücklauf **509** möglich.

Entsprechend der im Detail beschriebenen, vorliegenden Erfindung kann selbst bei einem größeren beweglichen Block durch eine Erhöhung der Anzahl von Eingußstellen an der Gußform ein korrekter Fluß des flüssigen Harzes sichergestellt werden und die Formgebung verbessert werden, da der aus Harz gebildete Körper, der den Rollkörperumlauf bildet, getrennt vom Blockkörper ausgebildet ist. Daher ist es von Vorteil, den aus Harz gebildeten Körper getrennt vom Blockkörper in Übereinstimmung mit der vorliegenden Erfindung auszubilden, wobei in Betracht gezogen wird, daß die den Rollkörperdurchlaß bildenden Abschnitte, die an den gegenüberliegenden Längsseiten der Rollkörperlaufbahn angeordnet sind, dünn sind, was wiederum zum Ergebnis hat, daß das flüssige Harz nicht jeden Teil des Raumes erreichen kann, der zur Formgebung der den Rollkörperdurchlaß bildenden Abschnitte vorgesehen ist.

Der durchgängige Umlauf wird durch den aus Harz gebildeten Körper gebildet, wodurch es möglich ist, eine Lagebestimmung der inneren Führungsrille des Richtungswechseldurchlasses relativ zu den den Rollkörperdurchlaß bildenden Abschnitte sowie eine Lagebestimmung der inneren Führungsrille des Richtungswechseldurchlasses relativ zum Rollkörperrücklauf durchzuführen, wodurch die Durchgängigkeit des Umlaufes und ein glatter Umlauf der Rollkörper sichergestellt wird.

Wenn der Verbindungsabschnitt der den Rollkörperdurchlaß bildenden Abschnitte und der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt oder der Verbindungsabschnitt des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes und der den Rücklauf bildenden Abschnitt, indem sich die Laufrichtung der Rollkörper ändert, durch einstückige Formgebung erhalten wird, ist es möglich, auf einen Zusammenbau des Verbindungsabschnittes zu verzichten und die Durchgängigkeit des Umlaufs sicherzustellen, ohne durch eine Genauigkeit bei einem Zusammenbau betroffen zu sein.

Die einstückige Formgebung des Verbindungsabschnittes des den Rollkörperumlauf bildenden Abschnittes zusammen mit der den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes führt zu einem glatten Umlauf der Rollkörper zwischen der Rollkörperlaufbahn im belasteten Bereich und dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt, selbst wenn der den Rücklauf bildende Abschnitt aus Harz nicht verwendet wird.

Wenn der Rollkörperkäfig verwendet wird, ist es möglich, eine vorteilhafte Durchgängigkeit am gesamten Umfang des Umlaufs im Käfigführungsabschnitt, der den Rollkörperkäfig führt, zu wahren.

Der dünne Käfigführungsabschnitt wird ohne Einsetzen des Körpers des beweglichen Teils in eine Gußform ausgebildet und die Lage der Eingußstellen in der Form kann frei bestimmt werden, ohne durch den Körper des beweglichen Blocks behindert zu sein, was zum Ergebnis hat, daß das flüssige Harz während der Bildung des Führungsabschnittes den gesamten, dafür in der Gußform vorgesehenen Raum erreichen kann.

Zusätzlich kann die Ausbildung von rechten und linken aus Harz gebildeten Körpern, die den Rollkörperumlauf bilden und jeweils zwei endlose Umläufe aufweisen, einen korrekten Fluß des flüssigen Harzes sicherstellen, selbst wenn der Körper des beweglichen Teils relativ weit ist.

Die Verbindung des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes mit dem den Rollkörperdurchlaß bildenden Abschnitt über den dünnen Plattenabschnitt ermöglicht durch die Verformung des dünnen Plattenabschnitts das Einhalten einer korrekten Lagebeziehung zwischen dem den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rollkörperdurchlaß bildenden Abschnitt oder einer korrekten Lagebeziehung zwischen der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitt und dem den Rollkörperrücklauf bildenden Abschnitt, wodurch eine genaue Lagebestimmung des Endes des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes relativ zu dem den Rollkörperrücklauf bildenden Abschnitt und eine genaue Lagebestimmung des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes relativ zu dem den Rollkörperrücklauf bildenden Abschnitt stattfindet.

Der dünne Plattenabschnitt wird durch eine Klemmkraft, die auf die seitliche Deckplatte wirkt, gegen die flache Stirnfläche des Körpers des beweglichen Teils drückt. Daher ist es möglich, die Lage des den Richtungswechseldurchlaß und innere Führung bildenden Abschnittes über die Verformung des dünnen Plattenabschnittes zu korrigieren, selbst wenn der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt nicht korrekt relativ zur Stirnfläche des Körpers des beweglichen Teils positioniert ist.

Zusätzlich kann der dünne Plattenabschnitt sicher zwischen der seitlichen Deckplatte und dem Körper des beweglichen Teils durch die Klemmkraft befestigt werden, die auf die seitliche Deckplatte wirkt, und daher ist es möglich zu verhindern, daß der den Richtungswechseldurchlaß und innere Führung bildende Abschnitt falsch plaziert wird.

Patentansprüche

1. Führungsvorrichtung für eine geradlinige Bewegung, die folgende Merkmale aufweist:
ein mit einer Rollkörperlaufbahn versehenes Führungsteil, und
ein bewegliches Teil, das derart angeordnet ist, daß entlang dem Führungsteil über eine große Anzahl von Rollkörpern beweglich ist, wobei das bewegliche Teil versehen ist mit (i) einer Rollkörpergegenlaufbahn, die der Rollkörperlaufbahn des Führungsteils entspricht (ii) einem Rollkörperrücklauf, der von der Rollkörpergegenlaufbahn in einem vorbestimmten Abstand parallel zu dieser angeordnet ist und (iii) ein Paar von Richtungswechseldurchlässen, die die Rollkörpergegenlaufbahn und den Rollkörperrücklauf verbinden und den Umlauf der Rollkörper ermöglichen,
dadurch gekennzeichnet, daß:
ein aus Harz gebildeter Körper, der den Rollkörperumlauf bildet, ein Paar von einen Rollkörperdurchlaß bildenden Abschnitten, die sich entlang der beiden in Längsrichtung verlaufenden Seiten der Rollkörpergegenlaufbahn erstrecken, einen den Rücklauf bildenden Abschnitt, der den Rollkörperrücklauf bildet, und ein Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte aufweist, die innere, in Umfangsrichtung verlaufende Führungsabschnitte der Richtungswechseldurchlässe bilden, wobei der aus Harz gebildete Körper getrennt von einem Körper des beweglichen Teils ausgebildet ist; und
zumindest zwei von (a) einem Paar der den Rollkörperdurchlaß bildenden Abschnitte, (b) einem den Rücklauf bildenden Abschnitt (c) einem des Paars der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte und (d) einem weiteren des Paares der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte durch einstückige Formgebung derart miteinander verbunden sind, daß der aus Harz gebildete Körper in den Körper des beweglichen Teils eingebaut werden kann.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß:
der aus Harz gebildete Körper (i) einen einstückigen Körper des Paars der den Rollkörperdurchlaß bildenden Abschnitte und des Paars der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte und (ii) den den Rücklauf bildenden Abschnitt getrennt vom einstückigen Körper ausgebildet aufweist.

3. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß:
der aus Harz gebildete Körper (i) einen einstückigen Körper des Paars der den Rollkörperdurchlaß bildenden Abschnitte, den den Rücklauf bildenden Abschnitt und einen vom Paar des den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte sowie (ii) einen weiteren des Paares der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte getrennt vom einstückigen Körper ausgebildet aufweist.

4. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß:
der aus Harz gebildete Körper durch Herstellung eines einstückigen Körpers aus dem Paar der den Rollkörperdurchlaß bildenden Abschnitte, des den Rücklauf bildenden Abschnittes und des Paars der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte und nachfolgender Teilung des Paars der den Rollkörperdurchlaß bildenden Abschnitte und des den Rücklauf bildenden Abschnittes in in Längsrichtung verlaufende Zwischenabschnitte in jeweils zwei Teile gebildet ist.

5. Führungsvorrichtung für eine geradlinige Bewegung, die folgende Merkmale aufweist:
ein mit einer Rollkörperlaufbahn versehenes Führungsteil und
ein bewegliches Teil, das derart angeordnet ist, daß es entlang dem Führungsteil über eine große Anzahl von Rollkörpern beweglich ist, wobei das bewegliche Teil (i) eine Rollkörpergegenlaufbahn, die der Rollkörperlaufbahn des Führungsteils entspricht, (ii) einen Rollkörperrücklauf, der in einem vorgegebenen Abstand von der Rollkörpergegenlaufbahn parallel zu dieser angeordnet ist und (iii) ein Paar von Richtungswechseldurchlässen aufweist, die die Rollkörpergegenlaufbahn und den Rollkörperrücklauf miteinander verbinden und den Umlauf der Rollkörper ermöglichen,
dadurch gekennzeichnet, daß:
ein aus Harz gebildeter Körper, der den Rollkörperumlauf bildet, ein Paar von den Rollkörperdurchlaß bildenden Abschnitten aufweist, die sich entlang der beiden in Längsrichtung verlaufenden Seiten der Rollkörpergegenlaufbahnen erstrecken, sowie ein Paar von den Richtungswechseldurchlaß und innere Führung bildenden Abschnitten aufweist, die innere, in Umfangsrichtung verlaufende Führungsabschnitte der Richtungswechseldurchlässe bilden, wobei der aus Harz gebildete Körper getrennt von einem Körper des beweglichen Teils ausgebildet ist;
der Rollkörperrücklauf durch Ausformung einer Durchgangsöffnung im Körper des beweglichen Teils gebildet ist; und
ein Paar von den Rollkörperdurchlaß bildenden Abschnitten und zumindest einer des Paars der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte durch einstückige Formgebung miteinander verbunden sind.

6. Vorrichtung nach einem der Ansprüche 1 bis 5, dadurch gekennzeichnet, daß:
ein Rollkörperkäfig vorgesehen ist, in dem die Rollkörper hintereinander in einem vorgegebenen Abstand zwischen Zwei benachbarten Rollkörpern aufnehmbar sind, wobei der Rollkörperkäfig Seitenkantenabschnitte aufweist, die von den beiden Seiten eines jeden Rollkörpers vorspringen; und
Führungsrillen, entlang derer die Seitenkantenabschnitte des Rollkörperkäfigs geführt sind, am gesamten Umfang des Rollkörperumlaufs ausgebildet sind.

7. Vorrichtung nach einem der Ansprüche 1 bis 6, dadurch gekennzeichnet, daß:
ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte einen dünnen Plattenabschnitt aufweist, der in Kontakt mit einer Stirnfläche des Körpers des beweglichen Teils bringbar ist, wobei jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte mit den den Rollkörperdurchlaß bildenden Abschnitten oder dem in Rücklauf bildenden Abschnitt durch den dünnen Plattenabschnitt verbunden ist.

8. Vorrichtung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß:
das Führungsteil eine Führungsschiene aufweist;
das bewegliche Teil einen beweglichen Block aufweist, der mit einem waagerechten Abschnitt versehen ist, welcher einer Oberfläche der Führungsschiene sowie einem Paar von Schenkelabschnitten gegenüberliegt, zwischen denen die Führungsschiene an deren rechten und linken Seitenflächen gehalten ist; und

zwei Rollkörperlaufbahnen in einer Lücke zwischen der Oberfläche der Führungsschiene und einer Unterfläche des beweglichen Blockes angeordnet sind und eine einzelne Rollkörperlaufbahn in einer jeden Lücke zwischen den rechten und linken Seitenflächen der Führungsschiene und den beiden Schenkelabschnitten angeordnet ist, so daß insgesamt vier Rollkörperlaufbahnen vorhanden sind.

9. Vorrichtung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß:
das Führungsteil eine Führungsschiene aufweist;
das bewegliche Teil einen beweglichen Block aufweist, der mit einem Paar von Schenkelabschnitten versehen ist, zwischen denen die Führungsschiene an deren rechten und linken Seitenfläche gehalten ist; und
zwei Rollkörperlaufbahnen in jeder der Lücken zwischen den rechten und linken Seitenflächen der Führungsschiene und den beiden Schenkelabschnitten angeordnet sind, so daß insgesamt vier Rollkörperlaufbahnen vorhanden sind.

10. Vorrichtung nach Anspruch 9, dadurch gekennzeichnet, daß:
vier den Richtungswechseldurchlaß und innere Führung bildende Abschnitte jeweils entsprechend den vier Kegellaufbahnen ausgebildet sind und die vier den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte einstückig miteinander verbunden sind.

11. Vorrichtung nach Anspruch 9, dadurch gekennzeichnet, daß:
zwei der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte, die an einer Seite der rechten Seitenfläche der Führungsschiene angeordnet sind, einstückig miteinander verbunden sind und die anderen beiden den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte, die an einer Seite der linken Seitenfläche der Führungsschiene angeordnet sind, einstückig miteinander verbunden sind.

12. Vorrichtung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß:
das Führungsteil eine Führungsschiene aufweist;
das bewegliche Teil mit einem waagerechten Abschnitt versehen ist, der einer Oberfläche der Führungsschiene gegenüberliegt, sowie mit einem einzelnen Schenkelabschnitt, der einer Seite der Führungsschiene gegenüberliegt; und
eine einzelne Rollkörperlaufbahn in einer Lücke zwischen einer Seitenfläche der Führungsschiene und dem einzelnen Schenkelabschnitt angeordnet ist und eine weitere Rollkörperlaufbahn in einer Lücke zwischen der Oberfläche der Führungsschiene und einer Unterfläche des waagerechten Abschnitts in der Umgebung einer Kante der Führungsschiene angeordnet ist.

13. Vorrichtung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß:
das Führungsteil eine Führungsschiene aufweist;
das bewegliche Teil einen beweglichen Block aufweist, der mit einem Paar von Schenkelabschnitten versehen ist, zwischen denen die Führungsschiene an deren rechten und linken Seitenflächen gehalten ist; und
eine Rollkörperlaufbahn in einer jeden Lücke zwischen den rechten und linken Seitenflächen der Führungsschiene und den beiden Schenkelabschnitten angeordnet ist, so daß insgesamt zwei Rollkörperlaufbahnen vorhanden sind.

14. Vorrichtung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß:
das Führungsteil eine Führungsschiene aufweist;
das bewegliche Teil einen beweglichen Block aufweist, der entlang einer Seitenfläche der Führungsschiene angeordnet ist; und
zwei Rollkörperlaufbahnen in einer Lücke zwischen der einen Seitenfläche der Führungsschiene und dem beweglichen Block angeordnet sind.

15. Vorrichtung nach einem der Ansprüche 1 bis 7, dadurch gekennzeichnet, daß:
das Führungsteil eine Keilwelle aufweist; und
das bewegliche Teil eine äußere Hülse aufweist, die über eine Vielzahl von Rollkörperlaufbahnen beweglich auf der Keilwelle gelagert ist.

16. Führungsvorrichtung für eine geradlinige Bewegung, die folgende Merkmale aufweist:
eine Führungsschiene, die mit zwei Rollkörperlaufbahnen an jeder der rechten und linken Seitenflächen der Führungsschiene versehen ist, so daß insgesamt vier Rollkörperlaufbahnen vorhanden sind; und
einen beweglichen Block, der mit einem Paar von Schenkelabschnitten versehen ist, zwischen denen die Führungsschiene an deren rechten und linken Seitenflächen gehalten ist, wobei jeder Schenkelabschnitt an dessen Innenfläche zwei Rollkörpergegenlaufbahnen aufweist, die den zwei Rollkörperlaufbahnen der Führungsschiene entsprechen, so daß insgesamt vier Rollkörpergegenlaufbahnen vorhanden sind, und wobei ferner der bewegliche Block Rollkörperrückläufe sowie vier endlose Umläufe aufweist, die durch vier Rollkörperrückläufe gebildet sind, die jeweils parallel zu den vier Rollkörpergegenlaufbahnen angeordnet sind, wobei die Rollkörperrückläufe die beiden Enden einer jeden Rollkörperlaufbahn jeweils mit den beiden Enden eines jeden Rollkörperrücklaufes verbinden,
dadurch gekennzeichnet, daß:
ein aus Harz gebildeter Körper bei einem jeden der endlosen Umläufe ein Paar von einen Rollkörperdurchlaß bildenden Abschnitten aufweist, die sich entlang der beiden in Längsrichtung verlaufenden Seiten der Rollkörpergegenlaufbahn erstrecken, sowie einen einen Rücklauf bildenden Abschnitt, der den Rollkörperrücklauf bildet, und ein Paar von einen Richtungswechseldurchlaß und innere Führung bildenden Abschnitten, die innere, in Umfangsrichtung verlaufende Führungsabschnitte der Richtungswechseldurchlässe bilden, wobei der aus Harz gebildete Körper getrennt von einem Körper des beweglichen Blockes ausgebildet ist;
der aus Harz gebildete Körper in zwei Teilkörper unterteilt ist, die jeweils an den Schenkelabschnitten des beweglichen Blockes angeordnet sind, so daß sie zwei endlose Umläufe an den Innenseiten eines jeden Schenkelabschnittes bilden; und
bei einem jeden der zwei Teilkörper die Rollkörpergegenlaufbahn und das Paar der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte als ein einstückiger Körper ausgebildet sind und der den Rücklauf bildende Abschnitt getrennt vom einstückigen Körper ausgebildet ist.

17. Vorrichtung nach Anspruch 16, dadurch gekennzeichnet, daß:
ein Rollkörperkäfig vorgesehen ist, in welchem Rollkörper hintereinander in einem vorbestimmten Abstand zwischen zwei benachbarten Rollkörpern aufnehmbar sind und der Seitenkantenabschnitte aufweist, die von den beiden Seiten eines jeden Rollkörpers hervorspringen; und
Führungsrillen zum Führen der Seitenkantenabschnitte des Rollkörperkäfigs am gesamten Umfang des Rollkörperumlaufs angeformt sind.

18. Vorrichtung nach Anspruch 16e oder 17, dadurch gekennzeichnet, daß:
ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte einen dünnen Plattenabschnitt aufweist, der eine Endfläche des Körpers des beweglichen Teils berührt, und wobei ein jeder der den Richtungswechseldurchlaß und innere Führung bildenden Abschnitte mit den den Rollkörperdurchlaß bildenden Abschnitten oder dem den Rücklauf bildenden Abschnitt durch den dünnen Plattenabschnitt verbunden ist

Die folgenden Angaben sind den vom Anmelder eingereichten Unterlagen entnommen

(54) Schmierölzufuhrsystem für Wälz- oder Rollführungsvorrichtung

(57) Die Erfindung betrifft ein Schmierölzufuhrsystem, das in einer Rollführungsvorrichtung vorgesehen ist, bei der eine Spurspindel bzw. -welle und ein Gleitteil über ein Rollelement, z. B. eine Kugel oder Rolle, im Eingriff stehen, und das eine auf dem Rollelement oder der Spurwelle gebildete Rollfläche des Rollelements schmiert, und insbesondere eine Verbesserung zur sicheren Schmierung der Rollführungsvorrichtung durch einen einfachen und billigen Aufbau. Das Schmierölzufuhrsystem weist auf: ein mit dem Schmieröl getränktes Zufuhrteil, das am Gleitteil befestigt ist und das Schmieröl auf die Rollfläche des Rollelements oder die Spurwelle bei einer Bewegung des Gleitteils aufträgt, einen Speichertank, der das Schmieröl aufnimmt und am beweglichen Element angeordnet ist, und einen Zufuhrschlauch, der ein verfitztes Faserelement im Inneren hat und das Schmieröl im Speichertank in das Zufuhrteil einleitet.

DE 197 54 454 A 1

Beschreibung

Die Erfindung betrifft ein Schmierölzufuhrsystem, das in einer Wälz- oder Rollführungsvorrichtung vorgesehen ist, bei der eine Spurspindel bzw. -welle und ein Gleitteil über ein Rollelement, z. B. eine Kugel oder Rolle, im Eingriff stehen, und das eine auf dem Rollelement oder der Spurwelle gebildete Rollfläche des Rollelements schmiert, und insbesondere eine Verbesserung zur sicheren Schmierung der Rollführungsvorrichtung durch einen einfachen und billigen Aufbau.

Herkömmlich bekannt als Rollführungsvorrichtung dieser Art ist eine Lineargleitvorrichtung, die für einen Linearführungsabschnitt einer Werkzeugmaschine oder einer Übergabevorrichtung verwendet wird und ein bewegliches Element, z. B. einen Tisch, auf einem feststehenden Abschnitt, z. B. einem Bett oder Sattel, führt, sowie eine Kugelgewindevorrichtung, die zusammen mit der Lineargleitvorrichtung verwendet wird und einen Linearbewegungshub in Übereinstimmung mit einem Drehbetrag eines Motors auf das bewegliche Element ausübt.

Die zuerst genannte Lineargleitvorrichtung weist auf: eine Spurschiene, die auf dem feststehenden Abschnitt angeordnet ist und eine in Längsrichtung gebildete Kugelrollnut hat, eine Lastrollnut, die der Rollnut der Spurschiene über mehrere Kugeln gegenüberliegt, und einen Gleittisch mit einem Endloskugelumlaufweg, der in der gebildeten Lastrollnut rollt, wobei der das bewegliche Element stützende Gleittisch kontinuierlich eine Linearbewegung auf der Spurschiene vollführt.

Andererseits weist die zuletzt genannte Kugelgewindevorrichtung auf: eine Gewindespindel bzw. -welle mit einer in vorbestimmter Steigung gebildeten spiralförmigen Kugelrollnut, eine Lastrollnut, die der Kugelrollnut über mehrere Kugeln gegenüberliegt, und ein Mutternteil mit einem Endloskugelumlaufweg, der in der Lastrollnut rollt, wobei die Kugeln im Endlosumlaufweg bei einer Relativdrehung zwischen der Gewindewelle und dem Mutternteil umlaufen und sich das Mutternteil kontinuierlich in Axialrichtung der Gewindewelle bewegt.

Bei Einsatz der vorgenannten Rollführungsvorrichtung ist es notwendig, Abrieb der Kugeln selbst oder Abrieb der Spurschiene oder Rollnut der Gewindewelle (im folgenden Spurwelle genannt), in der die Kugeln rollen, oder Abrieb der Lastrollnut des Mutternteils oder Gleittischs (im folgenden Gleitteil genannt) zu verhindern sowie die Kugel- und Lastrollnut zweckmäßig zu schmieren.

Herkömmlich bekannt als solches Schmierverfahren im Stand der Technik ist ein manuelles Ölzufuhrverfahren zur Ölzufuhr zum Gleitteil mit einer Fettpresse sowie ein Zwangs- bzw. Druckölzufuhrverfahren, bei dem vorab eine Ölzufuhrleitung mit dem Gleitteil verbunden und eine konstante Schmierölmenge in konstantem Abstand mit einer automatischen Pumpe unter Druck zugeführt wird. Ferner ist seit einigen Jahren ein Nebelschmierverfahren zum Durchpressen und Zuführen von zerstäubtem Schmieröl zusammen mit starker Druckluft durch eine mit dem Gleitteil verbundene Ölzufuhrleitung bekannt.

Indes muß beim manuellen Ölzufuhrverfahren Öl entsprechend dem Bewegungsweg des Gleitteils periodisch zugeführt werden, so daß bei langem Bewegungsweg des Gleitteils je Zeiteinheit häufig Öl zugeführt werden muß. Als problematisch erweist sich somit, daß dies beschwerlich ist.

Da hingegen beim vorgenannten Druckölzufuhrverfahren und Nebelschmierverfahren die Ölzufuhrleitung fest mit dem Gleitteil verbunden ist, so daß die Schmierölzufuhr automatisch erfolgt, gibt es keine Schwierigkeiten wie beim vorgenannten manuellen Ölzufuhrverfahren; allerdings sind die automatische Pumpe zur periodischen Schmierölzufuhr und die Pumpe zur starken Drucklufterzeugung notwendig. Somit ist problematisch, daß der Aufbau der Vorrichtung kompliziert wird und ihre Kosten steigen.

Zudem kann beim manuellen Ölzufuhrverfahren der Zeitpunkt der Ölzufuhr anhand des Schmierzustands der Rollnut der Spurwelle abgeschätzt werden, so daß Schmiermittelvergeudung kaum zu befürchten ist. Da aber beim Druck- oder Nebelschmierverfahren die vorbestimmte Menge ohne Rücksicht auf die tatsächlich verbrauchte Schmierölmenge quantitativ zum Gleitteil geführt wird, kommt es zu Schmierölvergeudung, was problematisch ist, da die Wartungskosten der Rollführungsvorrichtung steigen.

Die Erfindung berücksichtigt diese Probleme, und eine Aufgabe der Erfindung besteht darin, ein Schmierölzufuhrsystem bereitzustellen, das eine Rollführungsvorrichtung mit einem einfachen und billigen Aufbau schmieren und die Betriebskosten der Rollführungsvorrichtung bei Einschränkung der Schmierölverbrauchsmenge senken kann. Diese Aufgabe wird mit den Merkmalen der Ansprüche gelöst.

Wird gemäß der technischen Einrichtung der Erfindung das Schmieröl, mit dem das Zufuhrteil getränkt ist, zur Spurwelle bei Bewegung des Gleitteils geführt, erfolgt eine Schmierölzufuhr entsprechend der Schmierölverbrauchsmenge zum Zufuhrteil aus dem am beweglichen Element angeordneten Speichertank durch den Zufuhrschlauch.

Da hierbei der Zufuhrschlauch im Inneren mit dem verfitzten Faserelement gefüllt ist, wird auch bei Anordnung des Speichertanks über dem am Gleitteil befestigten Zufuhrelement das Schmieröl im Speichertank allmählich und langsam zum Zufuhrteil geführt, so daß die Schmierölmenge, mit der das Zufuhrteil getränkt ist, stets auf einem geeigneten Wert gehalten werden kann.

Da ferner auch bei Anordnung des Speichertanks auf gleicher oder etwas tieferer Höhe als das Zufuhrteil das Schmieröl im Speichertank allmählich in das Zufuhrteil durch Kapillarwirkung des verfitzten Faserelements im Zufuhrschlauch in Relation zur geringen durch den Auftrag verbrauchten Schmierölmenge gesaugt wird, kann das Schmieröl ohne Verwendung einer Preß- und Aufgabeeinrichtung, z. B. einer Pumpe, zum Zufuhrteil geführt werden.

Auch wenn gemäß dem Schmierölzufuhrsystem der Erfindung das Schmieröl im Speichertank aufgenommen ist, kann somit die Rollfläche des Rollelements oder der Spurwelle der Rollführungsvorrichtung ohne Einsatz eines speziellen maschinellen Werkzeugs, z. B. einer Pumpe, sicher geschmiert werden, wodurch die Schmierung einfach und billig erfolgt.

Bei Realisierung des erfindungsgemäßen Schmierölzufuhrsystems ist bevorzugt, daß der Zufuhrschlauch so aufgebaut ist, daß er frei am Speichertank zu befestigen und von ihm abzunehmen ist, und daß der Speichertank so aufgebaut ist, daß er frei am beweglichen Element zu befestigen und von ihm abzunehmen ist. Sind Speichertank und Zufuhrschlauch so aufgebaut, kann bei leerem Speichertank infolge von Schmierölverbrauch der gesamte Speichertank zur Schmierölzufuhr ausgetauscht werden, so daß keine Probleme infolge von Schmierölzufuhr in den leeren Speichertank entstehen.

Da erfindungsgemaß der Speichertank am beweglichen Element angeordnet ist, das sich auf der Spurwelle der Rollführungsvorrichtung bewegt, würde im Betrieb des beweglichen Elements das Schmieröl im Speichertank im Tank stark durchgeschüttelt und Blasen bilden, weshalb die Gefahr bestünde, daß das Schmieröl im Zufuhrschlauch nicht gleichmäßig fließt. Um solches Durchschütteln zu verhindern, ist daher bevorzugt, ein schmieröleinschließendes Element aus

Filz oder Polyurethan im Speichertank unterzubringen und das einschließende Element mit dem Schmieröl zu tränken.

Die aus dem Speichertank zum Zufuhrteil je Zeiteinheit geführte Schmierölmenge ist durch die Differenz der Anordnungshöhe zwischen beiden Teilen, die Dicke des Zufuhrschlauchs und die Schmierölviskosität beeinflußt; und ist die zur Schmierung der Spurwelle notwendige Schmierölmenge kleiner als die Schmierölzufuhrmenge zum Zufuhrteil, würde mehr Schmieröl als nötig auf die Spurwelle aufgetragen, so daß die Gefahr von Schmierölvergeudung bestünde. Deshalb ist bevorzugt, ein Durchflußmengen-Steuerventil zum Steuern der aus dem Speichertank zum Zufuhrteil geführten Schmierölmenge vorzusehen und nur das zur Schmierung der Rollfläche der Spurwelle notwendige Schmieröl zum Zufuhrteil zu führen, indem die Durchflußmenge des Schmieröls im Zufuhrschlauch mit dem Durchflußmengen-Steuerventil gesteuert wird.

Wie erwähnt wurde, kann gemäß dem Schmierölzufuhrsystem für die Rollführungsvorrichtung der Erfindung Schmieröl in einer Menge, die im wesentlichen gleich der Verbrauchsmenge im Zufuhrteil ist, aus dem Speichertank zum Zufuhrteil geführt werden, ohne eine Preß- und Aufgabeeinrichtung, z. B. Pumpe, zu verwenden, so daß die Rollführungsvorrichtung durch einen einfachen und billigen Aufbau geschmiert werden kann.

Da zudem das Zufuhrteil das Schmieröl auf das Rollelement oder die Spurwelle aufträgt, wird keine über das notwendige Maß hinausgehende große Schmierölmenge verbraucht, so daß sich die Schmierölverbrauchsmenge senken läßt.

Im folgenden wird ein erfindungsgemäßes Schmierölzufuhrsystem für eine Rollführungsvorrichtung anhand der beigefügten Zeichnungen beschrieben. Es zeigen:

Fig. 1 eine Perspektivansicht einer ersten Ausführungsform eines erfindungsgemäßen Schmierölzufuhrsystems;

Fig. 2 eine Querschnittansicht eines Verbindungszustands zwischen einem Zufuhrteil und einem Speichertank gemäß der ersten Ausführungsform;

Fig. 3 eine Explosionsansicht eines Anordnungszustands des Speichertanks an einem beweglichen Element gemäß der ersten Ausführungsform;

Fig. 4 eine Querschnittansicht einer zweiten Ausführungsform eines erfindungsgemäßen Schmierölzufuhrsystems;

Fig. 5 eine Querschnittansicht eines Durchflußsteuerventils gemäß der zweiten Ausführungsform;

Fig. 6 eine Perspektivansicht einer dritten Ausführungsform eines erfindungsgemäßen Schmierölzufuhrsystems; und

Fig. 7 eine Querschnittansicht eines Verbindungszustands zwischen einem Zufuhrteil und einem Speichertank gemäß der dritten Ausführungsform.

Fig. 1 zeigt eine erste Ausführungsform, in der ein Schmierölzufuhrsystem der Erfindung auf eine Lineargleitvorrichtung angewendet ist. In der Zeichnung bezeichnet die Bezugszahl **1** eine Lineargleitvorrichtung (Rollführungsvorrichtung), die aufgebaut ist aus einer Spurschiene (Spurwelle) **2**, die an einer (nicht gezeigten) feststehenden Position, z. B. einem Bett oder Sattel, befestigt ist, und einem Gleittisch (Gleitteil) **3**, der einen Eingriff mit der Spurschiene **2** über mehrere Kugeln herstellt und sich auf der Spurschiene **2** bewegt. Ferner bezeichnet die Bezugszahl **4** ein bewegliches Element, z. B. einen am Gleittisch **3** befestigten Tisch. In dieser Ausführungsform wird die Bewegung des beweglichen Elements **4** auf dem feststehenden Abschnitt durch zwei Spurschienen **2** und vier Gleittische **3** gestützt, von denen jeweils zwei einen Eingriff mit jeder der Spurschienen **2** herstellen.

Außerdem bezeichnet die Bezugszahl **5** ein Zufuhrteil, das an einem Endabschnitt des Gleittischs **3** in Bewegungsrichtung befestigt ist und das Schmieröl zur Spurschiene **2** bei der Bewegung des Gleittischs **3** führt, die Bezugszahl **6** bezeichnet einen Speichertank, der das zur Lineargleitvorrichtung **1** zu führende Schmieröl aufnimmt und am beweglichen Element **4** angeordnet ist, und die Bezugszahl **7** bezeichnet einen Zufuhrschlauch zum Zuführen des Schmieröls aus dem Speichertank **6** zum Zufuhrteil **5**.

Gemäß **Fig.** 2 ist eine Rollnut **9**, in der Kugeln **8** rollen, in der Spurschiene **2** gebildet, wogegen eine Lastrollnut **10** gegenüber der Kugelrollnut **9** der Spurschiene **2** im Gleittisch **3** gebildet ist, so daß die Kugeln **8** bei Lastausübung zwischen der Rollnut **9** und der Lastrollnut **10** rollen. Ferner ist ein Endlosumlaufweg **11** zum schließlichen Zurückführen der zu einem Ende der Lastrollnut **10** rollenden Kugeln **8** zu einem Anfang der Lastrollnut **10** im Gleittisch **3** gebildet, so daß sich der Gleittisch **3** kontinuierlich auf der Spurschiene **2** durch den Umlauf der Kugeln **8** im Endlosumlaufweg **11** bewegen kann.

Das Zufuhrteil **5** hat eine Kastenform mit einem Innenraum, wobei der Raum durch ein Gehäuse **12** mit einer zur Spurschiene **2** weisenden Öffnung und einem im Gehäuse **12** aufgenommenen schmierölhaltigen Element **13** gebildet ist, das mit der Spurschiene **2** in Berührung zu bringen und mit dem Schmieröl getränkt ist, und das Zufuhrteil **5** ist an der Endfläche des Gleittischs **3** in Bewegungsrichtung mit einem durch das Gehäuse **12** verlaufenden Befestigungsbolzen **14** befestigt. Das schmierölhaltige Element **13** reicht aus, solange es eine bestimmte Schmierölmenge absorbieren und halten kann, wobei ein Polyurethan- oder Filzmaterial zum Einsatz kommen können.

Bewegt sich der Gleittisch **3** auf der Spurschiene **2**, wischt das in Berührung mit der Spurschiene **2** gebrachte schmierölhaltige Element **13** über die Spurschiene **2**, wodurch das Schmieröl, mit dem das schmierölhaltige Element **13** getränkt ist, auf die Kugelrollnut **9** der Spurschiene **2** so aufgetragen wird, daß die in der Kugelrollnut **9** rollenden Kugeln **8** geschmiert werden.

Zudem ist das Zufuhrteil **5** mit dem am beweglichen Element **4** angeordneten Speichertank **6** über den Zufuhrschlauch **7** verbunden, so daß das im Speichertank **6** gespeicherte Schmieröl über den Zufuhrschlauch **7** vom schmierölhaltigen Element **13** im Zufuhrteil **5** absorbiert wird. In den Zufuhrschlauch **7** ist ein verfitztes Faserelement, z. B. aus Filz, so eingefügt, daß das Schmieröl im Speichertank **6** nicht auf einmal in das Zufuhrteil **5** fließt, sondern zum Zufuhrteil **5** unter Absorption durch das verfitzte Faserelement abgegeben wird.

Außerdem kann der Zufuhrschlauch **7** frei am Zufuhrteil **5** und Speichertank **6** angeordnet und davon abgenommen, wenn das schmierölhaltige Element **13** mit Schmieröl getränkt ist, und auch bei Entfernung des Zufuhrschlauchs **7** kann das Zufuhrteil **5** die Kugelrollnut **9** der Spurschiene **2** schmieren.

Dazu kommt, daß ein aus einem Filzmaterial hergestelltes schmierölgetränktes Element **15** in den Speichertank **6** eingefügt und das Schmieröl im Speichertank **6** in einem Zustand gespeichert ist, in dem es im schmierölgetränkten Element **15** gehalten wird. Da der Speichertank **6** am beweglichen Element **4** angeordnet ist, würde bei direkter Schmierölspeicherung im Tank **6** das Schmieröl im Speichertank **6** bei schnellem Hin- und Hergehen des beweglichen Elements **4** durchgeschüttelt, so daß die Gefahr von Blasenbildung im Schmieröl entstünde. Allerdings lassen sich diese Probleme vermeiden, wenn das im getränkten Element **15** absorbierte Schmieröl im Speichertank **6** gespeichert ist.

Gemäß **Fig.** 3 ragt ein hakenartiger Anordnungsabschnitt

16 von der Rückseite des Speichertanks **6** so vor, daß der Speichertank **6** am beweglichen Element **4** durch Einhängen des Anordnungsabschnitts **16** in eine am beweglichen Element **4** befestigte Halterung befestigt werden kann. Folglich läßt sich der Speichertank **6** frei am beweglichen Element **4** anordnen und von ihm abnehmen; ist das Schmieröl im Speichertank **6** verbraucht, wird ein neuer schmierölspeichernder Speichertank **6** wieder an der Halterung **17** angeordnet und der Zufuhrschlauch **7** vom alten Tank wieder am neuen Tank angeschlossen, so daß Schmieröl problemlos zugeführt werden kann. In dieser Ausführungsform ist der Speichertank **6** an der Seitenfläche des beweglichen Elements **4** angeordnet; sofern er nicht die in der Umgebung des beweglichen Elements **4** vorhandenen Ausrüstungen stört, kann der Speichertank **6** aber auch an der Ober- oder Unterseite des beweglichen Elements **4** angeordnet sein.

Bewegt sich gemäß dem so aufgebauten Schmierölzufuhrsystem der Erfindung ferner der Gleittisch **3** der Lineargleitvorrichtung **1** zusammen mit dem beweglichen Element, wischt das Zufuhrteil **5** durch das schmierölhaltige Element **13** bei der Bewegung über die Spurschiene **4**, so daß die Kugelrollnut **9** und die in ihr rollenden Kugeln **8** durch das Schmieröl geschmiert werden, mit dem das schmierölhaltige Element **13** getränkt ist. Die Schmierölmenge, mit der das schmierölhaltige Element **13** getränkt ist, verringert sich allmählich durch Wiederholen dieser Bewegung; da aber der Speichertank **6** mit dem Zufuhrteil **5** über den Zufuhrschlauch **7** verbunden ist, wird Schmieröl entsprechend der durch Auftragen auf die Spurschiene **2** verbrauchten Menge sukzessiv aus dem Speichertank **6** zugeführt.

Da hierbei das verfitzte Faserelement in den Zufuhrschlauch eingefügt ist, wird das Schmieröl im Speichertank **6** zum Zufuhrteil **5** unter Absorption durch das verfitzte Faserelement geführt, und andererseits wird im Zufuhrteil **5** das Schmieröl entsprechend der Verbrauchsmenge aus dem verfitzten Faserelement des Zufuhrschlauchs **7** durch das schmierölhaltige Element **13** absorbiert. Da hierbei der Speichertank **6** am durch den Gleittisch **3** gestützten beweglichen Element **4** angeordnet ist, besteht nahezu kein Höhenunterschied zwischen dem Gleittisch **3**, an dem das Zufuhrteil **5** befestigt ist, und dem Speichertank **6**, und selbst wenn der Speichertank **6** etwas tiefer als das Zufuhrteil **5** liegt, wird das Schmieröl im Speichertank **6** durch Kapillarwirkung des verfitzten Faserelements im Zufuhrschlauch **7** allmählich aufgesaugt.

Um festzustellen, wie weit das Schmieröl durch Kapillarwirkung im Zufuhrschlauch **7** aufsteigen kann, wurde im Rahmen der Erfindung ein Experiment durchgeführt. Der für das Experiment verwendete Zufuhrschlauch **7** wurde durch Einfügen eines Jutebands in einen transparenten Schlauch aus Vinylmaterial mit einem Innendurchmesser von etwa 3 mm hergestellt, und im Experiment wurde das untere Ende des Zufuhrschlauchs senkrecht abhängend in das Schmieröl eingetaucht. Es wurde als Ergebnis festgestellt, daß das Juteband im transparenten Schlauch mit Schmieröl getränkt wurde, das über einen Weg von etwa 50 bis 60 cm im Zufuhrschlauch **7** aufstieg. Auch wenn gemäß dem Ergebnis dieses Experiments das Zufuhrteil **5** etwa 50 bis 60 cm über dem Speichertank **6** positioniert ist, wurde somit festgestellt, daß das Schmieröl zum Zufuhrteil **5** geführt werden kann und nicht im Speichertank **6** verbleibt.

Ist dagegen der Speichertank **6** höher als das Zufuhrteil **5** angeordnet, dient das in den Zufuhrschlauch **7** eingefügte verfitzte Faserelement als Widerstand gegenüber dem Schmierölfluß auf dem Fließweg, so daß das Schmieröl im Speichertank **6** nicht auf einmal unter Schwerkrafteinfluß in das Zufuhrteil **5** fließt, sondern das schmierölhaltige Element **13** im Zufuhrteil **5** das Schmieröl aus dem Zufuhrschlauch **7** nur entsprechend dem Verbrauchsgrad aufnimmt.

Gemäß dieser Ausführungsform kann somit ohne Verwendung eines speziellen Mechanismus, z. B. einer Pumpe, das Schmieröl im Speichertank **6** zum Zufuhrteil **5** in einem der Verbrauchsmenge entsprechenden Grad abgegeben werden, so daß das Zufuhrteil **5** das Schmieröl kontinuierlich auf die Spurschiene **2** auftragen kann, bis das im Speichertank **6** gespeicherte Schmieröl verbraucht ist.

In **Fig.** 4 ist eine zweite Ausführungsform gezeigt, in der das erfindungsgemäße Schmierölzufuhrsystem auf eine Lineargleitvorrichtung angewendet ist.

Um gemäß dem Schmierölzufuhrsystem der zweiten Ausführungsform die Durchflußmenge des zum Zufuhrteil **5** aus dem Speichertank **6** geführten Schmieröls zu steuern, ist ein Durchflußmengen-Steuerventil **18** im Weg des den Speichertank **6** und das Zufuhrteil **5** verbindenden Zufuhrschlauchs **7** vorgesehen, wobei eine Betätigung des Durchflußmengen-Steuerventils **18** verhindert, daß Schmieröl in größerer Menge als notwendig zum Zufuhrteil **5** geführt wird.

Gebildet ist das Durchflußmengen-Steuerventil **18** gemäß **Fig.** 5 durch ein Gehäuse mit einem Durchflußkanal **19** für das Schmieröl und ein Handrad **22**, das in das Gehäuse **20** eingreift und einen an seinem vorderen Ende gebildeten nadelartigen Ventilkörper **21** hat, so daß der Ventilkörper **21** in einen im Weg des Durchflußkanals **19** gebildeten Ventilsitz **23** durch Betätigung des Handrads eingebracht und daraus entfernt wird, um so die Durchflußmenge des im Durchflußkanal **19** fließenden Schmieröls zu steuern. Hierbei bezeichnet die Bezugszahl **24** in der Zeichnung einen Verbindungsanschluß für den Zufuhrschlauch **7**.

Da gemäß dem so aufgebauten Schmierölzufuhrsystem der Erfindung die Durchflußmenge des aus dem Speichertank **6** zum Zufuhrteil **5** geführten Schmieröls wahlweise durch Betätigen des Durchflußmengen-Steuerventils **18** eingestellt werden kann, läßt sich eine optimale Schmierölmenge entsprechend der Nutzung der Lineargleitvorrichtung aus dem Zufuhrteil auf die Kugelrollnut **9** der Spurwelle **2** auftragen.

In der zweiten Ausführungsform ist der Aufbau so, daß das verfitzte Faserelement, z. B. Filz, nicht in den Innenabschnitt des Durchflußkanals **19** des Durchflußmengen-Steuerventils **18** eingefügt und der Durchflußkanal **19** nur mit dem Schmieröl gefüllt ist, wobei jedoch der Aufbau auch so sein kann, daß das verfitzte Faserelement sowohl in den Durchflußkanal **19** als auch den Zufuhrschlauch **7** eingefügt ist. In diesem Fall wird die Durchlaßmenge des Schmieröls, d. h. die Zufuhrmenge, durch Zusammendrücken des verfitzten Faserelements im Durchflußkanal **19** in Richtung auf den Ventilsitz **23** durch den Ventilkörper **21** sowie durch Ändern des Betrags, in dem es zusammengedrückt wird, eingestellt.

Fig. 6 und 7 zeigen eine dritte Ausführungsform, in der die Erfindung auf eine Kugelgewindevorrichtung angewendet ist.

In der Zeichnung bezeichnet die Bezugszahl **30** eine Gewindewelle (Spurwelle) mit einer in vorbestimmter Steigung gebildeten spiralförmigen Kugelrollnut **31**, die Bezugszahl **32** bezeichnet ein Mutternteil (Gleitteil), das eine Endlosspur, in der Kugeln **33** umlaufen, hat und einen Eingriff mit der Gewindewelle **30** über die Kugeln **33** herstellt, und die Bezugszahl **39** bezeichnet ein Zufuhrteil, das an beiden Endflächen des Mutternteils **32** in Längsrichtung angeordnet ist.

Gebildet ist das Mutternteil **32** hier durch einen Stahlmutternkörper **36**, der mit einem Flanschabschnitt **35** zum Befestigen des Mutternteils **32** auf vorstehende Weise versehen ist, mehrere Ablenkelemente bzw. Deflektoren **37**, die an einer Innenumfangsfläche des Mutternkörpers **36** befestigt sind, und ein Paar Abdichtungsteilen **38** zum Abdichten eines Spalts zwischen dem Mutternkörper und der Gewindewelle. Der Deflektor **37** ist am Mutternteil **32** so befestigt, daß er die Kugelrollnut **31** der Gewindewelle **30** nur in einem solchen Windungsgrad überspannt, daß die in der Kugelrollnut **31** der Gewindewelle **30** rollenden Kugeln **33** eine Richtungsänderung durch den Deflektor **37** erfahren und über den Außendurchmesser der Gewindewelle **30** laufen, um zur Kugelrollnut **31** eines vorherigen Windungszustands zurückgeführt zu werden. Folglich ist der Deflektor **37** so aufgebaut, daß die Kugeln **33** im Innenabschnitt des Mutternteils **32** im Endlosumlauf geführt werden. Ferner sind in dieser Ausführungsform vier Deflektoren **37** so am Mutternteil **32** befestigt, daß sie den Kreisumfang des Mutternteils **32** in vier gleiche Teile aufteilen, so daß die Endlosspur der Kugeln **33** alle vier Teile aufweist.

Andererseits ist der Aufbau so, daß ein Zufuhrteil **39** ein mit dem Schmieröl getränktes schmierölhaltiges Element **41** in einem Gehäuse **40** aufnimmt, und das schmierölhaltige Element **41** mit der Kugelrollnut **31** der Gewindewelle **30** auf die gleiche Weise wie in der ersten Ausführungsform in Berührung gebracht ist. Zudem ist das Zufuhrteil **39** am Mutternteil **32** durch einen (nicht gezeigten) Befestigungsbolzen befestigt.

Außerdem ist wie in der ersten und zweiten Ausführungsform das Zufuhrteil **39** mit dem Speichertank **6** durch den Zufuhrschlauch **7** verbunden, und der Aufbau ist so, daß das Schmieröl im Speichertank **6** zum Zufuhrteil **39** bei Abnahme des Schmieröls geführt wird, mit dem das schmierölhaltige Element **41** getränkt ist. Da der Aufbau des Speichertanks **6**, Zufuhrschlauchs **7** und Durchflußmengen-Steuerventils **18** dem der ersten und zweiten Ausführungsform gleicht, sind in der Zeichnung die gleichen Bezugszahlen für die gleichen Elemente vergeben, und auf ihre nähere Beschreibung wird verzichtet.

Werden im so aufgebauten Schmierölzufuhrsystem gemäß dieser Ausführungsform die Gewindewelle **30** und das Mutternteil **32** der Kugelgewindevorrichtung in Relativdrehung versetzt, trägt das Zufuhrteil **39** während der Drehung kontinuierlich das Schmieröl auf die Kugelrollnut **31** der Gewindeweile **20** auf, so daß die Schmierölmenge, mit der das schmierölhaltige Element **41** im Zufuhrteil **39** getränkt ist, allmählich abnimmt. Da aber der Speichertank **6** über den Zufuhrschlauch **7** mit dem Zufuhrteil **39** verbunden und das verfitzte Faserelement in den Zufuhrschlauch **7** eingefügt ist, wird das Schmieröl aus dem Speichertank **6** allmählich durch Kapillarwirkung zum Zufuhrteil **39** geführt, so daß ohne Einsatz eines speziellen Mechanismus, z. B. einer Pumpe, das Schmieröl entsprechend der Verbrauchsmenge nacheinander aus dem Speichertank **6** zum Zufuhrteil **39** geführt werden kann.

Patentansprüche

1. Schmierölzufuhrsystem mit einer Spurwelle und einem mit ihr über ein Wälz- oder Rollelement im Eingriff stehendes Führungsteil, die in einer Rollführungsvorrichtung zum Führen eines an dem Führungsteil befestigten beweglichen Elements auf der Spurwelle vorgesehen sind, und das eine Rollfläche des Rollelements oder ein auf der Spurwelle gebildetes Rollelement schmiert, mit:
einem mit Schmieröl getränktem Zufuhrteil, das an dem Führungsteil befestigt ist und das Schmieröl auf die Rollfläche des Rollelements oder die Spurwelle bei einer Bewegung des Führungsteils aufträgt, einem Speichertank, der das Schmieröl aufnimmt und an dem beweglichen Element angeordnet ist, und einem Zufuhrschlauch, der ein verfitztes Faserelement im Inneren hat und das Schmieröl aus dem Speichertank in das Zufuhrteil einleitet.

2. System nach Anspruch 1, wobei der Zufuhrschlauch an dem Speichertank frei anzuordnen und von ihm abzunehmen ist und der Speichertank an dem beweglichen Element frei anzuordnen und von ihm abzunehmen ist.

3. System nach Anspruch 1 oder 2, wobei ein das Schmieröl einschließendes Element in dem Speichertank aufgenommen und das einschließende Element mit dem Schmieröl getränkt ist.

4. System nach Anspruch 1, 2 oder 3, wobei ein Durchflußmengen-Steuerventil zum Steuern einer aus dem Speichertank zu dem Zufuhrteil geführten Schmierölmenge vorgesehen ist.

(54) Linearbewegungsvorrichtung

(57) Eine Linearbewegungsvorrichtung umfaßt eine geradlinige Führungsschiene mit einer Rollenlaufrille; eine Vorschubgewindestange, die drehbar parallel zur Führungsschiene angeordnet ist; und einen bewegbaren Block, der auf der Führungsschiene über Rollenkörper angeordnet und mit einem Mutternabschnitt, der eine Gewindebohrung aufweist, in die die Vorschubgewindestange einschraubbar ist, versehen ist. Der bewegbare Block umfaßt (i) einen Blockkörper mit einer Gegenrollenlaufrille, die der Rollenlaufrille der Führungsschiene zugekehrt ist und einen Rollenkörperrückführdurchlaß sowie (ii) Richtungswechseldurchlässe formende Teile, die jeweils auf beiden Seiten des Blockkörpers vorgesehen sind, wobei jedes der Teile einen U-förmigen Richtungswechseldurchlaß bildet, der die Gegenrollenlaufrille und den Rollenkörperrückführdurchlaß miteinander verbindet. Der bewegbare Block ist geradlinig auf der Führungsschiene durch Drehung der Vorschubgewindestange über die Rollenkörper geradlinig bewegbar. Der Mutternabschnitt ist einteilig auf dem den Richtungswechseldurchlaß bildenden Teil ausgebildet und eine Lage einer Mittelachse der Gewindebohrung des Mutternabschnittes wird durch das den Richtungswechseldurchlaß bildenden Teil aufgrund einer Lage der Gegenrollenlaufrille bestimmt.

DE 197 47 146 A 1

Beschreibung

HINTERGRUND DER ERFINDUNG

Gebiet der Erfindung

Die vorliegende Erfindung bezieht sich auf eine Linearbewegungsvorrichtung, bei der ein bewegbarer Block mit einem Mutternabschnitt, mit dem eine Vorschubgewindestange verschraubt ist, linear auf einer Führungsschiene durch Rotation der Vorschubgewindestange linear bewegt wird.

Beschreibung der verwandten Technik

Bei einer solchermaßen bekannten Linearbewegungsvorrichtung sind eine geradlinige Führungsschiene und eine drehbare Vorschubgewindestange parallel zueinander angeordnet und ein bewegbarer Block ist über eine große Anzahl von Rollkörpern bewegbar auf der Schiene angeordnet.

Der bewegbare Block ist mit einem Mutternabschnitt versehen, der eine Gewindebohrung aufweist, in die die Vorschubgewindestange geschraubt wird. Dementsprechend kann der bewegbare Block auf der Führungsschiene durch die Drehbewegung der Vorschubgewindestange bewegt werden.

Bei der oben beschriebenen, bekannten Linearbewegungsvorrichtung ist eine genaue Maschinenarbeit bezüglich des Parallelverlaufs einer Mittelachse der Gewindebohrung des Mutternabschnittes, der auf dem bewegbaren Block vorgesehen ist, zu einer Gegenrollenlaufrille des bewegbaren Blocks erforderlich, um einen leichten Lauf des bewegbaren Blocks zu erzielen. Aufgrund der Tatsache, daß der bewegbare Block und der Mutternabschnitt getrennt gefertigt werden, ist allerdings eine genaue Lage der Mittelachse der Gewindebohrung des Mutternabschnittes bezüglich der Gegenrollenlaufrille des bewegbaren Blocks schwer zu bestimmen. Da es desweiteren einen unvermeidbaren Arbeitsfehler bei der Fertigung des bewegbaren Blocks und des Mutternabschnittes gibt und darüber hinaus zusätzliche Teile zwischen diesen angeordnet sein können, ist auch die genaue Lage der Mittelachse der Gewindebohrung des Mutternabschnittes bezüglich der Gegenrollenlaufrille des bewegbaren Blocks schwer zu bestimmen. Aus diesem Grunde ist es schwierig, eine korrekte Gewindebohrung im Mutternabschnitt in einer genauen Lagebeziehung zur Gegenrollenlaufrille des bewegbaren Blocks maschinell herzustellen.

ZUSAMMENFASSUNG DER ERFINDUNG

Die vorliegende Erfindung hat daher zum Ziel, eine Linearbewegungsvorrichtung bereitzustellen, die einen einfachen Aufbau aufweist, einen korrekten Parallelverlauf der Mittelachse der Gewindebohrung des Mutternabschnittes, der auf dem bewegbaren Block vorgesehen ist, zu der Gegenrollenlaufrille des bewegbaren Blockes wahrt und einen leichten Lauf des bewegbaren Blocks ermöglicht.

Um das obenerwähnte Ziel zu erreichen, umfaßt die erfindungsgemäße Linearbewegungsvorrichtung folgende Merkmale:

Eine geradlinige Führungsschiene mit einer sich geradlinig erstreckenden Rollenlaufrille;

eine Vorschubgewindestange, die drehbar und parallel zu der Führungsschiene angeordnet ist; und

einen bewegbaren Block, der über eine große Anzahl von Rollkörpern bewegbar auf der Führungsschiene angeordnet und mit einem Mutternabschnitt mit einer Gewindebohrung, in die die Vorschubgewindestange einschraubbar ist, versehen ist;

wobei der bewegbare Block (i) einen Blockkörper mit einer Gegenrollenlaufrille, die der Rollenlaufrille der Führungsschiene zugekehrt ist, und mit einem Rollenrückführdurchlaß, der in einem vorbestimmten Abstand von der Gegenrollenlaufrille angebracht ist,

und (ii) ein Paar Richtungswechseldurchlässe bildende Teile aufweist, die jeweils auf beiden Enden des Blockkörpers vorgesehen sind, wobei ein jedes Teil einen U-förmigen Richtungswechseldurchlaß bildet, der die Gegenrollenlaufrille und den Rollenrückführdurchlaß miteinander verbindet;

wobei der bewegbare Block über die Rollenkörper auf der Führungsschiene durch eine Drehbewegung der Vorschubgewindestange linear bewegt wird;

dadurch gekennzeichnet, daß der Mutternabschnitt einteilig an zumindest einem der Richtungswechseldurchlässe bildenden Teile angeformt ist, und eine Lage einer Mittelachse der Gewindebohrung des Mutternabschnittes über zumindest ein die Richtungswechseldurchlässe bildendes Teil aufgrund der Lage der Gegenrollenlaufrille bestimmt wird.

Gemäß dem oben beschriebenen Merkmal der vorliegenden Erfindung ist es möglich, den genauen Parallelverlauf der Mittelachse der Gewindebohrung des Mutternabschnittes, der auf dem bewegbaren Block vorgesehen ist, zu der Gegenrollenlaufrille des bewegbaren Blocks zu erreichen, da die Lage der Mittelachse der Gewindebohrung des Mutternabschnittes direkt über das den Richtungswechseldurchlaß bildende Teil aufgrund der Lage der Gegenrollenlaufrille bestimmt wird.

Das oben erwähnte, den Richtungswechseldurchlaß bildende Teil kann ein Innenteil, das eine innere Führungsfläche für den Richtungswechseldurchlaß bildet, und ein Außenteil, das eine äußere Führungsfläche für den Richtungswechseldurchlaß bildet, aufweisen und der Mutternabschnitt kann einteilig am inneren Bauteil ausgebildet sein. Gemäß diesem Merkmal kann die Lage der Mittelachse der Gewindebohrung des Mutternabschnittes relativ zur Gegenrollenlaufrille noch genauer bestimmt werden, da das oben erwähnte, innere Bauteil mit dem Ende des Blockkörpers des bewegbaren Blocks, der die Rollenlaufrille aufweist, durchgängig verbunden ist.

Das oben erwähnte Innenteil des den Richtungswechseldurchlaß bildenden Bauteils und der Mutternabschnitt können am Blockkörper einteilig durch ein Verfahren zum Einsatzformen, bei dem die Lage des Blockkörpers aufgrund der Lage der Gegenrollenlaufrille in einer Gußform festgestellt und die Gußform mit einem Formmaterial gefüllt wird, ausgebildet sein. Die einteilige Ausbildung des Innenteils und des Mutternabschnittes mit dem Blockkörper ermöglicht es, eine genaue Lagebeziehung zwischen der Gegenrollenlaufrille des Blockkörpers und dem Mutternabschnitt festzustellen. Insbesondere wird das Innenteil fest am steifen Blockkörper befestigt und die Lage des Innenteils fest gesichert. Dadurch kann das Innenteil am Blockkörper wie geplant an Hand der Lage der Gegenlaufrille ausgestaltet werden und der Mutternabschnitt, der einteilig mit dem Innenteil ausgebildet ist, kann ebenfalls genau parallel zu der Gegenlaufrille ausgestaltet werden.

Das obenerwähnte, den Richtungswechseldurchlaß bildende Teil kann ein Innenteil, das eine innere Führungsfläche für den Richtungswechseldurchlaß bildet, und ein Außenteil, das eine äußere Führungsfläche des Richtungswechseldurchlasses bildet, aufweisen und der Mutternabschnitt kann einteilig am Außenteil ausgebildet sein. Gemäß diesem Merkmal kann die Lage der Mittelachse der Gewindebohrung des Mutternabschnittes relativ zu der Gegenrollenlaufrille genauer bestimmt werden, da die Lage des obenerwähnten Außenteils relativ zu der Gegenrollenlaufrille des Blockkörpers festgestellt wird.

Der obenerwähnte Mutternabschnitt weist vorzugsweise einen Schlitz auf, der am Mutternabschnitt ausgebildet ist und ihn in zwei Teile teilt. Die Phasengänge der Mutterngewindeabschnitte der getrennten Teile des Mutternabschnittes weichen voneinander ab. Gemäß diesem Merkmal ist es möglich, den toten Gang zwischen der Vorschubgewindestange und dem Mutternabschnitt zu verringern, wodurch ein genauer und präziser Lauf des bewegbaren Blocks ermöglicht wird.

Ein Mechanismus zur Abstandseinstellung kann zwischen den getrennten Teilen des Mutternabschnittes vorgesehen sein, um die Gewindegänge des Mutterngewindeabschnittes der obenerwähnten getrennten Teile des Mutternabschnittes voneinander abweichen zu lassen. Gemäß diesem Merkmal ist es möglich, zwischen der Vorschubgewindestange und dem Mutternabschnitt eine größere Vorspannung aufzubringen.

KURZE BESCHREIBUNG DER ZEICHNUNGEN

Fig. 1 zeigt eine Draufsicht, die eine Linearbewegungsvorrichtung gemäß der ersten Ausführungsform der vorliegenden Erfindung erläutert;

Fig. 2 zeigt eine Vorderansicht der Linearbewegungsvorrichtung nach **Fig.** 1;

Fig. 3 zeigt eine Schnittansicht entlang einer Linie A-A in **Fig.** 1;

Fig. 4 zeigt eine Schnittansicht entlang einer Linie B-B in **Fig.** 2;

Fig. 5 zeigt eine Schnittansicht, die eine Linearbewegungsvorrichtung gemäß der zweiten Ausführungsform der vorliegenden Erfindung erläutert.

GENAUE BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSFORMEN

Im folgenden werden die erfindungsgemäßen Ausführungsformen, wie in den Zeichnungen gezeigt, genauer beschrieben.

Fig. 1 bis 4 erläutern die Linearbewegungsvorrichtung der ersten Ausführungsform der vorliegenden Erfindung.

Eine geradlinige Führungsschiene **2** und eine Vorschubgewindestange **3** sind parallel zueinander zwischen einem Paar Lagerkörper angeordnet. Die Vorschubgewindestange kann mittels eines Antriebsmotors **4** gedreht werden. Ein bewegbarer Block **5** ist auf der Führungsschiene **2** linear bewegbar über eine große Anzahl von Rollkörpern **6**, beispielsweise Kugeln, angeordnet.

Der bewegbare Block **5** ist mit einem Mutternabschnitt **8** mit einer Gewindebohrung, in die die obenerwähnte Vorschubgewindestange **3** geschraubt wird, versehen.

Die Führungsschiene **2** ist mit einem Paar Rollenlaufrillen **9** versehen, die sich geradlinig erstrecken.

Der bewegbare Block **5** umfaßt einen Blockkörper **12** und ein Paar den Richtungswechseldurchlaß bildende Teile **14**. Der Blockkörper **12** weist eine Gegenrollenlaufrille **10**, die der Rollenlaufrille der Führungsschiene **2** zugekehrt ist, und einen Rollenrückführdurchlaß **11** auf, der in einem vorbestimmten Abstand von der Gegenrollenlaufrille **10** angeordnet ist. Die den Richtungswechseldurchlaß bildenden Teile **14** sind jeweils auf beiden Enden des Blockkörpers **12** vorgesehen. Jedes der den Richtungswechseldurchlaß bildende Teile **14** bildet einen U-förmigen Richtungswechseldurchlaß **13**, der die Gegenrollenlaufrille **10** und den Rollenrückführdurchlaß **11** miteinander verbindet.

Der obenerwähnte Mutternabschnitt **8** ist einteilig am Richtungswechseldurchlaß bildenden Teil **14** ausgebildet. Die Lage der Mittelachse der Gewindebohrung **7** des Mutternabschnittes **8** wird durch das den Richtungswechseldurchlaß bildende Teil **14** aufgrund der Lage der Gegenrollenlaufrille **10** bestimmt.

Insbesondere weist das den Richtungswechseldurchlaß bildende Teil **14** ein Innenteil **15** aus Kunstharz, das eine innere Führungsfläche **13**a für den U-förmigen Richtungswechseldurchlaß **13** bildet, und eine Seitenplatte **16** aus Kunstharz als ein Außenteil, das eine äußere Führungsfläche **13**b für den Richtungswechseldurchlaß **13** bildet, auf. In der ersten Ausführungsform der vorliegenden Erfindung ist der Mutternabschnitt **8** einteilig am obenerwähnten Innenteil **15** ausgebildet.

Die Lage der Mittelachse der Gewindebohrung **7** des Mutternabschnittes **8** wird direkt durch das Innenteil **15** des den Richtungswechseldurchlaß bildenden Teils **14** aufgrund der Lage der Gegenrollenlaufrille **10** auf diese Weise bestimmt. Das Innenteil **15** ist durchgängig mit dem Ende des Blockkörpers **12** des bewegbaren Blockes **5**, der die Gegenrollenlaufrille **10** aufweist, verbunden. Dadurch ist es möglich, den genauen Parallelverlauf der Mittelachse der Gewindebohrung **7** des Mutternabschnittes **8** zu der Rollenlaufrille **10** des bewegbaren Blocks **5** zu erreichen. Der obenerwähnte Aufbau verbessert den Parallelverlauf der Mittelachse der Gewindebohrung **7** des Mutternabschnittes **8** zu der Gegenrollenlaufrille **10** des bewegbaren Blocks **5**. Selbst wenn ein Verarbeitungsfehler im Parallelverlauf der Mittelachse der Gewindebohrung **7** des Mutternabschnittes **8** zur Gegenrollenlaufrille **10** des bewegbaren Blocks **5** und/oder im Parallelverlauf der Führungsschiene **2** zur Vorschubgewindestange **3** auftritt, können das Innenteil **15** und dem dazu einteilig ausgebildeten Mutternabschnitt **8**, die beide aus Kunstharz bestehen, einen solchen Verarbeitungsfehler ausgleichen.

Zusätzlich sind in der ersten Ausführungsform der vorliegenden Erfindung das Innenteil **15** des den Richtungswechseldurchlaß bildenden Teils **14** und der Mutternabschnitt **8** einteilig durch ein Verfahren zum Einsatzformen, bei dem die Lage des Blockkörpers **12** aufgrund der Lage der Gegenrollenlaufrille **10** in einer Gußform bestimmt und die Gußform mit Kunstharz als Formmaterial gefüllt wird, einteilig am Blockkörper **12** ausgebildet. In dieser Ausführungsform ist der Mutternabschnitt **8** auf einer Seite des Blockkörpers **12**, d. h. der Vorschubgewindestangenseite des Blockkörpers **12**, angeordnet und jede der beiden Endflächen des Blockkörpers **12** wird durch das Innenteil **15** und einem aus Kunstharz gebildeten, einteilig daran angeformten Abschnitt bedeckt, die beide auch einteilig mit dem Mutternabschnitt **8** gestaltet sind. Des weiteren wird die Innenfläche des Rollenrückführdurchlasses **11** des Blockkörpers **12** durch einen aus Kunstharz geformten Abschnitt **20** bedeckt, der einteilig mit dem Innenteil **15** und dem aus Kunstharz geformten Abschnitt **19** ausgebildet ist.

Wenn das Innenteil **15** und der Mutternabschnitt **8** in dieser Art einteilig mit dem Blockkörper **12** gebildet sind, ist es möglich, die genaue Lagebeziehung zwischen der Gegenrollenlaufrille **10** des Blockkörpers und dem Mutternabschnitt **8** zu bestimmen. Insbesondere ist das Innenteil fest an dem Blockkörper **12**, der eine hohe Steifigkeit aufweist, befestigt und die Lage des Innenteils ist fest gesichert. Daher kann das Innenteil **15** am Blockkörper **12** genau geformt werden, wie aufgrund der Lage der Gegenrollenlaufrille **10** vorgesehen. Der Mutternabschnitt **8**, der einteilig mit dem Innenteil **15** ausgebildet ist, kann ebenfalls genau parallel zu der Gegenrollenlaufrille **10** ausgebildet werden.

Zusätzlich weist der Mutternabschnitt **8** einen Schlitz **17** auf, der auf dem Mutternabschnitt **8** ausgebildet ist und ihn in zwei Teile teilt, wobei die Phasengänge der Mutterngewindeabschnitte der beiden Teile **81, 81** voneinander abweichen.

Bei diesem Aufbau wird eine niedrige Vorspannung auf die Vorschubgewindestange **3** durch die Rückstellkraft, die von der Elastizität der getrennten Teile **81, 81** des Mutternabschnittes **8** erzeugt wird, aufgebracht. Daher ist es möglich, den toten Gang zwischen der Vorschubgewindestange **3** und dem Mutternabschnitt **8** zu verringern und so den genauen und präzisen Lauf des bewegbaren Blockes **5** zu ermöglichen.

Wenn ein Mechanismus **18** zum Einstellen eines Abstandes, wie beispielsweise einer Einstellschraube, die die Phasengänge der Mutterngewindeabschnitte der getrennten Teile **81, 81** des Mutternabschnittes **8** zueinander verstellt, zwischen den getrennten Teilen **81, 81** wie in einer doppelt strichpunktierten Linie in **Fig.** 1 gezeigt, vorgesehen ist, so ist es möglich, eine größere Vorspannung zwischen der Vorschubgewindestange **3** und dem Mutternabschnitt **8** aufzubringen.

Im folgenden wird die Linearbewegungsvorrichtung gemäß der zweiten Ausführungsform der vorliegenden Erfindung unter Bezugnahme auf **Fig.** 5 beschrieben.

In der zweiten Ausführungsform der vorliegenden Erfindung ist der Mutternabschnitt **8** einteilig mit der Seitenplatte **16** als ein Außenteil gestaltet, obwohl der Mutternabschnitt **8** einteilig mit dem Innenteil **15** des den Richtungswechseldurchlaß bildenden Teils **14** in der ersten Ausführungsform der vorliegenden Erfindung einteilig ausgestaltet ist.

Die Lage der Seitenplatte **16** als Außenteil wird relativ zur Gegenrollenlaufrille **10** des Blockkörpers **12** bestimmt. Dadurch kann die Lage der Mittelachse der Gewindebohrung **7** des Mutternabschnittes **8** bezüglich der Gegenrollenrücklaufrille **10** genauer bestimmt werden.

Dieser Gesichtspunkt wird im folgenden genau erläutert. Das Innenteil **15**, das einen Teil des den Richtungswechseldurchlaß bildenden Teils **14** darstellt, wird einteilig mit dem Blockkörper **12** an Hand der Lage der Gegenrollenrücklaufrille **10** des Blockkörpers **12** ausgestaltet. Der Blockkörper **12** weist eine so hohe Steifigkeit auf, daß er sich im wesentlichen nicht verformt, und folglich wird die Lage des Innenteils **15**, das fest am Blockkörper **12** befestigt ist, fixiert. Wenn die Innenteile **15**, die jeweils auf beiden Enden des Blockkörpers **12** angeordnet sind, einteilig miteinander entlang der axialen Richtung des Blockkörpers **12** durch Abschnitte aus Kunstharz (nicht gezeigt) verbunden sind, mit denen die Ober- oder Seitenflächen des Blockkörpers **12** und die inneren Umflächen des Rollkörperrückführdurchlasses **11** bedeckt sind, dann werden die Innenteile **15** durch die obenerwähnten, aus Kunstharz geformten Abschnitten begrenzt, eine feste Befestigung der Innenteile **15** am Blockkörper **12** möglich ist.

Die Seitenplatte **16** wird andererseits als ein äußerer Führungsabschnitt für den Richtungswechseldurchlaß **13** zur selben Zeit geformt, zu der ein Muttergewinde zur Bildung des Gewindeloches **7** im Mutternabschnitt **8** geformt wird. Aus diesem Grund kann im Mutternabschnitt **8** die Gewindebohrung **7** mit ihrer axialen Flucht wie geplant ausgestaltet werden und die äußere Führungsfläche **13**b der Seitenplatte **16** kann ebenfalls wie geplant gebildet werden.

Der Richtungswechseldurchlaß **13** wird dadurch gebildet, daß die innere Führungsfläche **13**a des Innenteils **15**, das auf der Endfläche des Blockkörpers **12** ausgebildet ist, der äußeren Führungsfläche **13**b der Seitenplatte **16** zugekehrt wird. Die beiden Enden des solchermaßen gebildeten Richtungswechseldurchlasses **13** sind jeweils mit der Gegenrollenrücklaufrille **10** und dem Rollenkörperrücklaufdurchlaß **11** verbunden, um eine korrekte Ausrichtung dieser Teile zu erhalten. Die glatte Durchgängigkeit des Richtungswechseldurchlasses **13**, der Gegenrollenrücklaufrille **10** und des Rollenkörperrücklaufdurchlasses **11** ist sichergestellt, womit ein glatter Umlauf der Rollenkörper **6** ermöglicht wird.

Das Innenteil **15** und die Seitenplatte **16** als ein Außenteil sind derart ausgebildet, daß die innere Führungsfläche **13**a des Innenteils **15** der äußeren Führungsfläche **13**b der Seitenplatte **16** gegenüber zu liegen kommt und den Richtungswechseldurchlaß **13** bildet. Dabei ist die Seitenplatte **16** fest bezüglich der Seitenfläche des Blockkörpers **12** befestigt und der Mutternabschnitt **8** ist einteilig mit der Seitenplatte **16** ausgebildet. Dadurch ist eine genaue Bestimmung der Lage der Mittelachse der Gewindebohrung **7** des Mutternabschnittes **8** bezüglich der Gegenrollenlaufrille **10** des Blockkörpers **12** genau zu bestimmen und die Beibehaltung des korrekten Parallelverlaufs der Mittelachse der Gewindebohrung **7** des Mutternabschnittes **8** zu der Gegenrollenlaufrille **10** des Blockkörpers **12** möglich.

In der oben beschriebenen zweiten Ausführungsform der vorliegenden Erfindung ist der Mutternabschnitt **8** einteilig mit einem der Paare von Seitenplatten **16,16** ausgebildet. Zwei Mutternabschnitte **8, 8** können jedoch auch einteilig mit jeweils den beiden Seitenplatten **16, 16** ausgebildet sein. In solch einem Fall ist es im Gegensatz zu der ersten und zweiten Ausführungsform der vorliegenden Erfindung nicht notwendig, einen Schlitz auf dem Mutternabschnitt zu fertigen, um eine Vorspannung auf die Vorschubgewindestange **3** aufzubringen.

Gemäß der vorliegenden, im Detail beschriebenen Erfindung ist es möglich, einen genauen Parallelverlauf der Mittelachse der Gewindebohrung des Mutternabschnittes, die auf dem bewegbaren Block vorgesehen ist, zu der Gegenrollenlaufrille des bewegbaren Blocks zu erhalten, da die Lage der Mittelachse der Gewindebohrung des Mutternabschnittes direkt durch das den Richtungswechseldurchlaß bildende Teil aufgrund der Lage der Gegenrollenlaufrille bestimmt ist.

Wenn der Mutternabschnitt einteilig am Innenteil des den Richtungswechseldurchlasses bildenden Teils ausgebildet ist, so kann die Lage der Mittelachse der Gewindebohrung des Mutternabschnittes genauer zu der Gegenrollenlaufrille bestimmt werden, da das oben angeführte Innenteil durchgängig mit dem Ende des Blockkörpers des bewegbaren Blockes, der die Gegenrollenlaufrille aufweist, verbunden ist.

Wenn das oben erwähnte Innenteil des den Richtungswechseldurchlaß bildenden Teils und der Mutternabschnitt einteilig am Blockkörper mittels eines Verfahrens mit einer Einsatzform ausgebildet werden, bei der die Lage des Blockkörpers aufgrund der Lage der Gegenrollenlaufrille in einer Gußform bestimmt und die Gußform mit einem Formmaterial gefüllt wird, ist die Bestimmung der genauen Lagebeziehung zwischen der Gegenrollenlaufrille des Blockkörpers und des Mutternabschnittes möglich.

Wenn der Mutternabschnitt einteilig am Außenteil des den Richtungswechseldurchlaß bildenden Teils ausgebildet ist, kann die Lage der Mittelachse der Gewindebohrung des Mutternabschnittes bezüglich der Gegenrollenlaufrille genauer bestimmt werden, da die Lage des obenerwähnten Außenteils relativ zu der Gegenrollenlaufrille des Blockkörpers bestimmt ist.

Wenn der obenerwähnte Mutternabschnitt einen Schlitz aufweist, der den Mutternabschnitt in zwei Teile teilt und wenn die Phasengänge der Mutterngewindeabschnitte der getrennten Teile des Mutternabschnittes voneinander abweichen, ist es möglich, den toten Gang zwischen der Vorschubgewindestange und dem Mutternabschnitt zu reduzieren und so die genaue und präzise Bewegung des bewegbaren Blockes zu ermöglichen.

Wenn ein Mechanismus zur Abstandseinstellung zwischen den getrennten Teilen des Mutternabschnittes vorgesehen ist, um die Phasengänge der Mutterngewindeabschnitte der obenerwähnten getrennten Teile des Mutternabschnittes voneinander abweichen zu lassen, dann ist es möglich, eine höhere Vorspannung zwischen der Vorschubgewindestange und dem Mutternabschnitt aufzubringen.

Patentansprüche

1. Linearbewegungsvorrichtung, die folgende Merkmale umfaßt:
Eine geradlinige Führungsschiene (**2**) mit einer sich geradlinig erstreckenden Rollenlaufrille (**9**);
eine Vorschubgewindestange (**3**), die drehbar und parallel zu der Führungsschiene (**2**) angeordnet ist; und
einen bewegbaren Block (**5**), der auf der Führungsschiene (**2**) über eine große Anzahl von Rollenkörpern (**6**) bewegbar angeordnet ist und bei dem ein Mutternabschnitt (**8**), der eine Gewindebohrung (**7**) aufweist, in die die Vorschubgewindestange (**3**) einschraubbar ist, vorgesehen ist;
wobei der bewegbare Block (**5**) (i) einen Blockkörper (**12**) mit einer Gegenrollenlaufrille (**10**), die der Rollenlaufrille (**9**) der Führungsschiene (**2**) zugekehrt ist, und
mit einem Rollenrückführdurchlaß (**11**), der in einem vorbestimmten Abstand von der Gegenrollenlaufrille (**10**) angeordnet ist und (ii) ein Paar von Richtungswechseldurchlässen bildenden Teilen (**14**), die jeweils an beiden Enden des Blockkörpers (**12**) vorgesehen sind, wobei jedes der Teile einen U-förmigen Richtungswechseldurchlaß (**13**) bildet, der die Gegenrollenlaufrille (**10**) und den Rollenrückführdurchlaß (**11**) miteinander verbindet, aufweist;
der bewegbare Block (**5**) ist durch Drehung der Vorschubgewindestange (**3**) geradlinig auf der Führungsschiene (**2**) über die Rollenkörper (**6**) bewegbar;
dadurch gekennzeichnet, daß der Mutternabschnitt (**8**) einteilig an zumindest einem der den Richtungswechseldurchlaß bildenden Teile (**14**) ausgebildet ist und daß eine Lage einer Mittelachse der Gewindebohrung (**7**) des Mutternabschnittes (**8**) durch zumindest einem der den Richtungswechseldurchlaß bildenden Teile (**14**) an Hand einer Lage der Gegenrollenlaufrille (**10**) bestimmt wird.

2. Linearbewegungsvorrichtung nach Anspruch 1, wobei das den Richtungswechseldurchlaß bildende Teil (**14**) ein Innenteil (**15**), das eine innere Führungsfläche (**13**a) für den Richtungswechseldurchlaß (**13**) bildet, und ein Außenteil (**16**), das eine äußere Führungsfläche (**13**b) für den Richtungswechseldurchlaß (**13**) bildet, aufweist, und wobei der Mutternabschnitt (**8**) einteilig an dem Innenteil (**15**) ausgestaltet ist.

3. Linearbewegungsvorrichtung nach Anspruch 2, wobei das Innenteil (**15**) des den Richtungswechseldurchlaß bildenden Teils (**14**) und der Mutternabschnitt (**8**) einteilig an dem Blockkörper (**12**) mittels eines Einsatzformverfahrens, in der eine Lage des Blockkörpers (**12**) aufgrund einer Lage der Gegenrollenlaufrille (**10**) in einer Gußform festgestellt und die Gußform mit einem Formmaterial gefüllt wird, ausgebildet sind.

4. Linearbewegungsvorrichtung nach Anspruch 1, wobei das den Richtungswechseldurchlaß bildende Teil (**14**) ein Innenteil (**15**), das eine innere Führungsfläche (**13**a) für den Richtungswechseldurchlaß (**13**) bildet, und ein Außenteil (**16**), das eine äußere Führungsfläche (**13**b) für den Richtungswechseldurchlaß (**13**) bildet, aufweist, und wobei der Mutternabschnitt (**8**) einteilig an dem Außenteil (**16**) ausgebildet ist.

5. Linearbewegungsvorrichtung nach einem der Ansprüche 1 bis 3, wobei der Mutternabschnitt (**8**) einen Schlitz (**17**) aufweist, der auf dem Mutternabschnitt (**8**) ausgebildet ist und den Mutternabschnitt (**8**) in zwei Teile teilt, wobei Phasengänge der Mutterngewindeabschnitte der getrennten Teile des Mutternabschnittes (**8**) voneinander abweichen.

6. Linearbewegungsvorrichtung nach Anspruch 5, wobei ein Mechanismus zur Abstandseinstellung zwischen den getrennten Teilen des Mutternabschnittes (**8**) vorgesehen ist, um die Phasengänge der Mutterngewindeabschnitte der getrennten Teile des Mutternabschnittes (**8**) voneinander abweichen zu lassen.

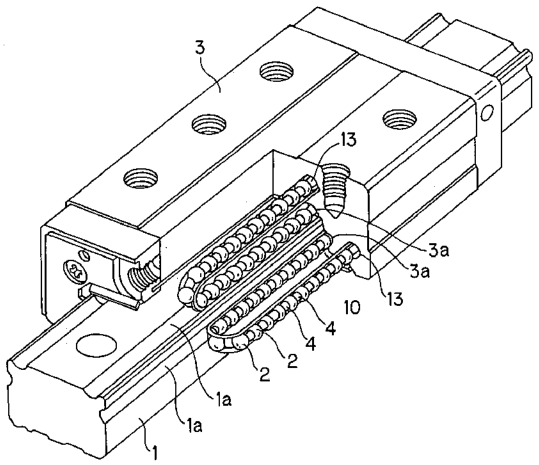
(54) Bezeichnung: **Bewegungsführungsvorrichtung, Kugelumlaufspindel und Verfahren zum Formen einer Kugellaufrille**

(57) Hauptanspruch: Bewegungsführungsvorrichtung, aufweisend ein Führungsteil und ein bewegbares Teil, bei welcher wenigstens eines des Führungsteils und des bewegbaren Teils mit einer Kugellaufrille versehen ist, die als eine Führungsbahn zu einer Zeit wirkt, wenn eine zwischen dem Führungsteil und dem bewegbaren Teil angeordnete Kugel wälzt,
wobei eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen an der Kugellaufrille derart ausgebildet sind, dass sie sich in einer Richtung erstrecken, in welcher sich die Kugellaufrille erstreckt, und wobei die Kugel, die der Belastung zwischen dem Führungsteil und dem bewegbaren Teil ausgesetzt ist, die mehreren vorstehenden Streifen vor dem Kontaktieren ausgesparter Abschnitte zwischen den mehreren vorstehenden Streifen kontaktiert.



Beschreibung

Technisches Gebiet

[0001] Die vorliegende Erfindung betrifft eine Bewegungsführungsvorrichtung zum Führen einer Linearbewegung oder Drehbewegung eines zu führenden Gegenstandes, bei welcher eine Anzahl von Kugeln, die eine Wälzbewegung durchführen, zwischen einem Spurteil und einem bewegbaren Teil angeordnet sind, oder betrifft eine Kugelumlaufspindel, bei welcher eine Anzahl von Kugeln, die eine Wälzbewegung durchführen, zwischen einer Spindelwelle und einer Mutter angeordnet sind.

Stand der Technik

[0002] Eine Kugellaufrille ist an einem Führungsteil und einem bewegbaren Teil einer Bewegungsführungsvorrichtung als eine Führungsbahn ausgebildet, entlang welcher die Kugeln wälzen. Verschiedene Formen können von der Kugellaufrille entsprechend einer Weise, wie die Last als ein Gegenstand zu tragen ist, angenommen werden.

[0003] Fig. 12 zeigt eine Schnittansicht einer Kugellaufrille. Die Kugellaufrillen umfassen zwei typische Arten von Kreisbogenrille und Spitzbogenrille. Wie in Fig. 12A gezeigt ist, hat die Kreisbogenrille eine Querschnittsform eines Kreisbogens, und wenn die Kugel zwischen dem Führungsteil und dem bewegbaren Teil geklemmt ist, die beide die Kreisbogenrillen aufweisen, kontaktiert die Kugel diese an zwei Punkten, daher „Zweipunktkontakt" genannt. Andererseits hat, wie in Fig. 12B gezeigt ist, die Spitzbogenrille eine Querschnittsform von zwei Kreisbögen, so dass die Kugel üblicherweise an vier Punkten kontaktiert, daher „Vierpunktkontakt" genannt. (Zum Beispiel mit Bezug auf die folgende Nichtpatentliteratur 1).

[0004] Bei der Zweipunktkontaktform sind zwei Kontaktpunkte einander gegenüberliegend, wobei die Kugel dazwischen angeordnet ist, und bei der Vierpunktkontaktform sind vier Kontaktpunkte in einem Winkelabstand von etwa 90 Grad in Bezug auf die Mitte der Kugel ausgebildet. Ferner kann, wenn auch in einem seltenen Fall, eine Dreipunktkontaktform angenommen werden, bei welcher drei Kontaktpunkte in einem gleichen Winkelabstand in Bezug auf die Mitte der Kugel ausgebildet sind. Bei jeder dieser Formen bildet jeder Kontaktpunkt einen Punktkontakt zwischen der Kugel und einer glatten gekrümmten Fläche.

[Nichtpatentliteratur 1]

„Ursprung des Linearsystems", herausgegeben von Linear System Edditing Commissioner, am 15. Juni 2000, Seite 40, von Shimizu und anderen (neun).

[0005] Bei einer herkömmlichen Bewegungsführungsvorrichtung mit einer glatten Kugellaufrille wird die Tragfähigkeit jeder Kugel durch geometrische Formen und Werkstoffe der Kugel und der Kugellaufrille eindeutig bestimmt. Aus diesem Grunde wurde, um die Tragfähigkeit unter Verwendung der Kugeln mit demselben Werkstoff und derselben Abmessung zu erhöhen, ein Verfahren zur Anpassung des Krümmungsradius der Kugellaufrille an den Radius der Kugel angewendet. Jedoch erfordert die Technologie der Anpassung des Krümmungsradius der Kugellaufrille an den Radius der Kugel eine hohe Arbeitsleistung, wodurch die Herstellungskosten steigen, was daher industriell nachteilig ist.

Offenbarung der Erfindung

[0006] Dementsprechend ist es ein Ziel der vorliegenden Erfindung, eine Bewegungsführungsvorrichtung, eine Kugelumlaufspindel und ein Verfahren zu deren Herstellung zu schaffen, ohne den Krümmungsradius der Kugellaufrille an den Radius der Kugel anzupassen.

[0007] Die vorliegende Erfindung wird nachfolgend beschrieben. Um das obige Ziel zu erreichen, konzipierten die Erfinder eine Struktur, bei welcher eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen (Rippen), die sich in einer Richtung erstrecken, entlang welcher sich die Kugellaufrille erstreckt, in der Nähe des Kontaktpunktes der Kugellaufrille in einer Weise ausgebildet sind, dass eine die Last tragende Kugel die mehreren vorstehenden Streifen kontaktiert.

[0008] Das heißt, die Erfindung nach Anspruch 1 stellt eine Bewegungsführungsvorrichtung bereit, bei welcher wenigstens eines des Führungsteils und des bewegbaren Teils mit einer Kugellaufrille als eine Führungsbahn zu einer Zeit, wenn eine zwischen dem Führungsteil und dem bewegbaren Teil angeordnete Kugel wälzt, versehen ist, wobei eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen in der Kugellaufrille derart ausgebildet sind, dass sie sich in einer Richtung erstrecken, in welcher sich die Kugellaufrille erstreckt, und wobei die Kugel, die der Belastung zwischen dem Führungsteil und dem bewegbaren Teil ausgesetzt ist, die mehreren vorstehenden Streifen vor dem Kontaktieren ausgesparter Abschnitte zwischen den mehreren vorstehenden Streifen kontaktiert.

[0009] Gemäß dieser Erfindung werden die Kugel und die Kugellaufrille in einer Mehrzahl von Kontaktpunkten, und nicht einem, miteinander kontaktiert, so dass die auf die Kugel ausgeübte Belastung auf die mehreren Punkte verteilt wird und daher das Auftreten einer hohen Spannungskonzentration in einem bestimmten Punkt verhindert werden kann. Darüber hinaus wirkt, da sich die Mehrzahl von vorstehenden

Streifen gleichmäßig in einer Richtung erstrecken, in welcher sich die Kugellaufrille erstreckt, keinerlei Kraft zur Änderung der Drehachse der Kugel und folglich zur Änderung der Drehung der Kugel während des Wälzens der Kugel. Daher wird selbst bei dem Vorhandensein eines Kontaktpunktes oder mehrerer Kontaktpunkte keinerlei Einfluss auf den Widerstand während des Wälzens der Kugel ausgeübt.

[0010] Es ist erwünscht, dass die vorstehenden Streifen derart elastisch verformt werden, dass die Kugel den ausgesparten Abschnitt kontaktiert.

[0011] Gemäß dieser Erfindung kann, da der vorstehende Abschnitt elastisch verformt wird und eine breite Kontaktfläche zwischen der Kugel und der Kugellaufrille sichergestellt werden kann, eine breite Lastfläche an der Kugellaufrille sichergestellt werden.

[0012] Die Bewegungsführungsvorrichtung der vorliegenden Erfindung kann vorzugsweise für eine lineare oder gekrümmte Bewegungsführungsvorrichtung oder ein Wälzlager verwendet werden, bei welchem ein ringförmiges bewegbares Teil an einem ringförmigen Führungsteil drehbar montiert ist.

[0013] Ferner stellt die vorliegende Erfindung eine Kugelumlaufspindel bereit, die eine Spindelwelle und eine Mutter aufweist, bei welcher spiralförmige Kugellaufrillen als ein Führungsteil, das zu einer Zeit wirkt, wenn eine zwischen der Spindelwelle und der Mutter angeordnete Kugel wälzt, in der Spindelwelle und der Mutter ausgebildet sind, wobei eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen in den Kugellaufrillen derart ausgebildet sind, dass sie sich in einer Richtung erstrecken, in welcher sich die Kugellaufrillen erstrecken, und wobei die Kugel, die der Belastung zwischen dem Führungsteil und dem bewegbaren Teil ausgesetzt ist, die mehreren vorstehenden Streifen vor dem Kontaktieren ausgesparter Abschnitte zwischen den mehreren vorstehenden Streifen kontaktiert.

[0014] Noch darüber hinaus kann das obige Ziel durch die vorliegende Erfindung erreicht werden, indem ein Verfahren zum Formen einer Kugellaufrille bereitgestellt wird, bei welchem wenigstens eines des Führungsteils und des bewegbaren Teils mit einer Kugellaufrille als eine Führungsbahn versehen ist, die zu einer Zeit wirkt, wenn eine zwischen dem Führungsteil und dem bewegbaren Teil angeordnete Kugel wälzt, wobei das Verfahren die Schritte aufweist: Bewegen eines scheibenförmigen Fräsers oder Schleifsteins mit einem Radius, der kleiner als jener der Kugel ist, in einer Richtung, in welcher sich die Kugellaufrille erstreckt, und Übertragen einer Außenumfangsform des scheibenförmigen Fräsers oder Schleifsteins auf die Kugellaufrille; Bewegen des Fräsers oder Schleifsteins in einer Ebene senkrecht zu einer Richtung, in welcher sich die Kugellaufrille erstreckt; und Bewegen des Fräsers oder Schleifsteins in der Richtung, in welcher sich die Kugellaufrille erstreckt, und Übertragen der Außenumfangsform des scheibenförmigen Fräsers oder Schleifsteins auf die Kugellaufrille, wobei eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen derart geformt werden, dass sie sich in der Richtung erstrecken, in welcher sich die Kugellaufrille erstreckt.

[0015] Gemäß dieser Erfindung können die mehreren ausgesparten Abschnitte einen Krümmungsradius bereitstellen, der kleiner als der Radius der Kugel ist, so dass die Kugel und die Kugellaufrille in einer Mehrzahl von Kontaktpunkten, und nicht einem kontaktieren.

KURZBESCHREIBUNG DER ZEICHNUNGEN

[0016] Fig. 1 ist eine perspektivische Ansicht (mit einem teilweisen Schnitt) einer Bewegungsführungsvorrichtung (Linearführung) gemäß einer ersten Ausführungsform der vorliegenden Erfindung.

[0017] Fig. 2 ist eine Schnittansicht einer endlosen Umlaufbahn entlang einer Erstreckungsrichtung einer endlosen Umlaufbahn der Bewegungsführungsvorrichtung der obigen Ausführungsform.

[0018] Fig. 3 ist eine Schnittansicht der Kugellaufrille in einer Ebene senkrecht zu der Erstreckungsrichtung der Kugellaufrille.

[0019] Fig. 4 ist eine Ansicht, die eine Verteilung einer erzeugten Spannung (Von Mses Spannung) darstellt (in dem Fall, dass die Kugel und die glatte Fläche in einem Punkt kontaktieren).

[0020] Fig. 5 ist eine Ansicht, die eine Verteilung einer erzeugten Spannung (Von Mses Spannung) darstellt (in dem Fall, dass die Kugel und die glatte Fläche in zwei Punkten kontaktieren.

[0021] Fig. 6 ist eine Ansicht, die eine Verteilung einer erzeugten Scherkraft (XY Scher) darstellt (in dem Fall, dass die Kugel und die glatte Fläche in einem Punkt kontaktieren.

[0022] Fig. 7 ist eine Ansicht, die eine Verteilung einer erzeugten Scherkraft (XY Scher) darstellt (in dem Fall, dass die Kugel und die glatte Fläche in zwei Punkten kontaktieren).

[0023] Fig. 8 ist eine Ansicht, die ein Verfahren zum Formen einer Kugellaufrille zeigt (Schnittansicht in einer Richtung senkrecht zu der Kugellaufrille).

[0025] Fig. 10 ist eine perspektivische Ansicht einer Kugelumlaufspindel gemäß einer dritten Ausführungsform der vorliegenden Erfindung.

[0026] Fig. 11 ist eine Schnittansicht eines Radialwälzlagers gemäß einer vierten Ausführungsform der vorliegenden Erfindung.

[0027] Fig. 12 ist eine Schnittansicht einer herkömmlichen üblichen Kugellaufrille (in welcher Fig. 12A eine Kreisbogenrille und Fig. 12B eine Spitzbogenrolle zeigt).

BEVORZUGTE AUSFÜHRUNGSFORM DER ERFINDUNG

[0028] Fig. 1 zeigt eine perspektivische Ansicht einer Bewegungsführungsvorrichtung gemäß der ersten Ausführungsform der vorliegenden Erfindung, welche eine Linearführung als eine lineare Bewegungsführungsvorrichtung zeigt. Die Linearführung ist mit einer Führungsschiene **1** als ein Führungsteil und einem bewegbaren Block **3** als bewegbares Teil versehen, der an der Führungsschiene **1** mittels einer Anzahl von Kugeln **2** verschiebbar montiert ist. Die Führungsschiene **1** ist ein sich längs erstreckendes Teil, das derart ausgebildet ist, dass es eine etwa rechteckige Querschnittsform senkrecht zu der Längsrichtung der Führungsschiene **1** bildet, und Kugellaufrillen **1a**, **1a**, die Führungsbahnen während des Wälzens der Kugel bilden, sind in deren oberen Fläche und beiden Seitenflächen entlang einer gesamten Länge der Führungsschiene **1** ausgebildet.

[0029] Ferner kann die Führungsschiene **1** eine lineare Struktur oder eine gekrümmte Struktur aufweisen, und in der dargestellten Ausführungsform kann, obwohl zwei Reihen von Kugellaufrillen **1a**, **1a** an jeder der seitlichen Seiten ausgebildet sind, d.h. insgesamt vier an beiden Seiten, die Anzahl solcher Reihen von Rillen entsprechend dem Gebrauch, der Gegenstände oder ähnlich der Linearführung verändert werden.

[0030] Der bewegbare Block **3** ist auch mit Kugellaufrillen **3a**, **3a** versehen, die den Kugellaufrillen **1a**, **1a** entsprechen, die in der Führungsschiene **1** ausgebildet sind. Eine Lastlaufbahn **12** ist zwischen der entsprechenden Kugellaufrille **1a** der Führungsschiene **1** und der Kugellaufrille **3a** des bewegbaren Blockes **3** ausgebildet, zwischen welchen eine Anzahl von Kugeln **2**, **2** in einem Klemmzustand angeordnet sind. Der bewegbare Block **3** ist ferner mit vier Reihen von Rücklaufbahnen **13**, **13**, die sich jeweils parallel zu den Kugellaufrillen **1a**, **1a** erstrecken, und Umlenkbahnen **5** versehen, die jeweils die entsprechende Lastlaufbahn **12** und Rücklaufbahn **13** verbinden. Dementsprechend wird durch die Kombination von einer Lastlaufbahn **12**, einer Rücklaufbahn **13** und einem Paar Umlenkbahnen **5**, die diese Lastlaufbahn **12** und die Rücklaufbahn **13** an deren beiden Enden verbinden, eine endlose Umlaufbahn gebildet, wie in Fig. 2 gezeigt ist.

[0031] Fig. 2 ist eine Schnittansicht der endlosen Umlaufbahn in deren Erstreckungsrichtung. In jeder der endlosen Umlaufbahnen sind eine Anzahl von Kugeln **2**, **2** in einem Kettenverbindungszustand mittels Kupplungsteilen **8** untergebracht. Das Kupplungsteil **8** ist mit einer Anzahl von Abstandsstücken **4**, **4** versehen, die in einem vorbestimmten Abstand benachbart zueinander angeordnet sind, und einem Paar Riemen **10**, **10** versehen, die diese Abstandsstücke **4**, **4** an ihren Seitenabschnitten verbinden. Die Kugel **2** ist zwischen den benachbarten Abstandsstücken **4**, **4** angeordnet und gehalten. Flächen der Abstandsstücke **4**, die den Kugelflächen zugewandt sind, sind als sphärisch ausgesparte Flächen derart ausgebildet, dass sie mit der Außenfläche der Kugel übereinstimmen, wodurch der direkte Kontakt der Kugeln **2**, **2** verhindert werden kann und ein sanfter Kugelumlauf in der endlosen Umlaufbahn sichergestellt werden kann.

[0032] Entsprechend der Bewegung des bewegbaren Blocks **3** entlang der Führungsschiene **1** führen die Kugeln **2**, **2** die Wälzbewegung in der Lastlaufbahn **12** von deren einem Ende zu deren anderem Ende unter Belastung durch, werden dann in die eine Umlenkbahn **5** geschoben, und werden danach zu der Rücklaufbahn **13** geführt. Die Kugeln **2**, **2** werden danach weiter in die andere Umlenkbahn **5** geschoben und dann zu dem ersten Ende der Lastlaufbahn **12** zurückgeführt.

[0033] Fig. 3 zeigt eine Schnittansicht der Kugellaufrille **1a** in einer Ebene senkrecht zu der Richtung, entlang welcher sich die Kugellaufrille **1a** erstreckt. Allgemein bildet die Kugellaufrille **1a**, die eine Führungsbahn während des Wälzens der Kugel bildet, eine glatte Fläche und hat eine Form, die uneingeschränkt einer geometrischen Kreisbogenform entspricht. Andererseits sind in der vorliegenden Ausführungsform eine Mehrzahl von vorstehenden Streifen (Rippen) **7** in der Nähe der Kontaktpunkte zwischen der Kugel **2** und der Kugellaufrille **1a** derart ausgebildet, dass sie sich entlang der Kugellaufrille **1a** erstrecken. Dieser vorstehende Streifen **7** bildet keine rauhe Fläche mit beliebigen Aussparungen und Vorsprüngen, sondern hat eine gleichmäßige Form in der Kugelvorlaufrichtung (in einer Richtung senkrecht zu dem Zeichnungsblatt) und kontaktiert die Kugel **2** in einer Mehrzahl von Punkten in einer Ebene senkrecht zu der Kugelvorlaufrichtung. Das Profil der Kugellaufrille **1a**, an welcher die vorstehenden Streifen **7**, **7** ausgebildet sind, kann derart geformt sein, dass es eine Kreisbogenrillenform, Spitzbogenrillenform oder glatte, flache ebene Form bildet.

[0034] Auf die Kugel **2**, die zwischen der Führungsschiene **1** und dem bewegbaren Block **3** angeordnet ist, wird eine Belastung ausgeübt. Die Kugel, auf welche die Belastung einwirkt, kontaktiert, wie in Fig. 3(A) gezeigt ist, die mehreren vorstehenden Streifen **7**, bevor sie die ausgesparten Abschnitte **39**, **39** zwischen den vorstehenden Streifen **7**, **7** kontaktiert. Das heißt, in einem Zustand, in dem die Kugel in der Kugellaufrille platziert ist (d.h. in einem unbelasteten Zustand), kontaktiert die Kugel **2** nur die paarweise vorstehenden Streifen **7**, **7** und kontaktiert nicht die ausgesparten Abschnitte **39**, **39**. wenn die Belastung auf die Kugel **2** ausgeübt wird, wie in Fig. 3(B) gezeigt ist, werden die vorstehenden Streifen **7**, **7** elastisch verformt, und die Kugel **2** kontaktiert auch die ausgesparten Abschnitte **39**, **39**. Zu der Zeit, wenn die Kugel **2** die ausgesparten Abschnitte **39**, **39** zwischen den vorstehenden Streifen **7**, **7** kontaktiert, werden die vorstehenden Streifen **7**, **7** elastisch verformt, jedoch nicht plastisch verformt. Aus diesem Grunde kehren, wenn die Kugel **2** von der Belastung freigegeben wird, die vorstehenden Streifen **7**, **7** in den unbelasteten Zustand zurück, wie in Fig. 3(A) gezeigt ist.

[0035] Die Teilung der vorstehenden Streifen **7**, **7** wird zum Beispiel in der folgenden Weise bestimmt. Es gibt eine vorausberechnete Kontaktfläche zwischen der Kugel **2** und der Kugellaufrille **1a** bei einer angenommenen Belastung, zum Beispiel einer statischen Tragzahl. Bei einer solchen Kontaktfläche wird die Teilung der vorstehenden Streifen **7**, **7** derart festgelegt, dass drei bis vier Streifen der Vorsprünge **7**, **7** die Kugel **2** kontaktieren. Der Begriff „statische Tragzahl" bedeutet hierbei eine statische Last mit konstanter Richtung und Größe derart, dass an dem Kontaktabschnitt, auf den die maximale Spannung ausgeübt wird, die Summe der permanenten Verformung der Kugel **2** und der permanenten Verformung der Kugellaufrille **1a** das 1/10000-fache des Durchmessers der Kugel **2** ist.

[0036] Die mehreren vorstehenden Streifen **7**, **7** wirken als Schienen, auf welchen die Kugeln wälzen. Wenn die Kugel **2** entlang der Kugellaufrille **1a** wälzt, hat die Kugel **2** eine Drehachse **14**. In einer Situation, in der eine Kraft zur Begrenzung der Drehachse **14** ausgeübt wird, wird eine Reibung an dem Kontaktpunkt zwischen der Kugel **2** und der Kugellaufrille **1a** verursacht. In dem Fall, dass die Kugel **2** in nur einem Punkt die Kugellaufrille **1a** mit der vollständigen Kreisbogenform kontaktiert, und in dem Fall, dass die Kugel **2** in zwei Punkten die paarweise vorstehenden Streifen **7**, **7** kontaktiert, wird keine Kraft verursacht, welche die Kugel **2** begrenzt. Dementsprechend wird sogar bei Vorhandensein der vorstehenden Streifen **7**, **7** weniger Einfluss auf den Widerstand in der Kugellaufrichtung ausgeübt.

[0037] Außerdem wird die auf die Kugel **2** ausgeübte Belastung in einer Mehrzahl von Punkten, und nicht in einem Punkt gehalten, die Kontaktfläche wird im Vergleich zu der Belastung frühzeitig erweitert, und die Tragfähigkeit kann in Übereinstimmung mit der erweiterten Größe der Kontaktfläche groß gestaltet werden.

[0038] Fig. 4 bis Fig. 7 zeigen Ergebnisse des Analysierens von Spannungen und Scherkräften mit FEM (Finite Elemente Verfahren), die in dem Fall, dass die Kugel und die glatte Fläche in einem Punkt kontaktieren, und in dem Fall, dass die Kugel und die glatte Fläche in zwei Punkten kontaktieren, erzeugt werden. Hierbei wird eine Belastung von bestimmter Größe auf die Kugel mit einem Durchmesser von 12,7 mm derart ausgeübt, dass sie heftig gegen die glatte Fläche von 5 µm oder gegen den vorstehenden Abschnitt mit einer Höhe von 3 bis 5 µm gedrückt wird. Fig. 4 bis Fig. 7 zeigen den Kontaktabschnitt zwischen der Kugel und der glatten Fläche in vergrößerten Maßstäben.

[0039] Fig. 4 und Fig. 5 zeigen die Verteilung der erzeugten Spannung (Von Mses Spannung), in welchen Fig. 4 den Fall zeigt, dass die Kugel und die glatte Fläche in einem Punkt wie üblich kontaktieren, und Fig. 5 den Fall zeigt, dass die Kugel und die glatte Fläche in zwei Punkten kontaktieren, und in welchen dieselben Schraffurlinien für Abschnitte mit äquivalenter oder derselben Spannung beschrieben sind.

[0040] Wie in Fig. 5 gezeigt ist, beginnen in dem Fall von zwei Kontaktpunkten die Kugel und die glatte Fläche in zwei Punkten zu kontaktieren, die mit einem Freiraum zwischen ihnen leicht voneinander getrennt sind. Es wird beobachtet, dass, wenn die Belastung auf die Kugel **2** ausgeübt wird, die Belastung auch auf die beiden getrennten Punkte ausgeübt wird und sich dann die Kontaktfläche zwischen der Kugel und der glatten Fläche innerhalb und außerhalb der vorstehenden Abschnitte ausbreitet. Somit wird die Spannung dementsprechend vollständig verteilt, und eine große Spannung wird kaum verursacht.

[0041] Fig. 6 und Fig. 7 zeigen Verteilungen der erzeugten Scherkräfte (XY Scher), in welchen Fig. 6 den Fall zeigt, das die Kugel und die glatte Fläche in einem Punkt wie üblich kontaktieren, und Fig. 7 den Fall zeigt, dass die Kugel und die glatte Fläche in zwei Punkten kontaktieren, und in welchen dieselben Schraffurlinien für Abschnitte mit äquivalenter oder derselben Scherkraft beschrieben sind.

[0042] Der bedeutendste Aspekt bei der Betrachtung der Zerstörung der Kugel ist die maximale Scherkraft. Wenn auf die Kugel die Belastung ausgeübt wird, ist ein Abschnitt, an welchem die maximale Scherkraft ausgeübt wird, etwas innerhalb des Kontaktpunktes der Kugel positioniert, und wenn eine Kraft eine Gleitbewegung an dem Abschnitt verursacht, an welchem die maximale Scherkraft wirkt, wird das Material zerstört.

[0043] Wie in Fig. 7 gezeigt ist, wird festgestellt, dass in dem Fall von zwei Kontaktpunkten ein Bereich, in welchem die Scherkraft erhöht ist, reduziert wird, und die Scherkraft wird vollständig verteilt.

[0044] Fig. 8 zeigt ein Verfahren zum Formen (Herstellen) der Kugellaufrille **1a**. Ein scheibenförmiger Schleifstein **15** mit einem Durchmesser, der kleiner als der Radius der Kugel **2** ist, wird zuerst bereitgestellt. Als nächstes wird der Schleifstein **15** in einer Richtung (Richtung senkrecht zu diesem Zeichnungsblatt), in welcher sich die Kugellaufrille **1a** erstreckt, unter Drehung bewegt, und die Kugellaufrille **1a** wird durch die Außenumfangsfläche des Schleifsteins **15** von einer unbearbeiteten Arbeitsfläche zu einer glatten Lauffläche geschliffen, so dass die Kugellaufrille **1a** die Lauffläche übereinstimmend mit der Außenumfangsfläche des Schleifsteins **15** bereitstellt. Als nächstes wird der Schleifstein **15** zum Beispiel aus der Schleifsteinposition Nr. 9 in die Schleifsteinposition Nr. 10 in Fig. 8 in der Ebene senkrecht zu der Richtung, in welcher sich die Kugellaufrille erstreckt, in einem vorbestimmten Abstand bewegt. Der Schleifstein **15** wird wieder in der Richtung bewegt, in welcher sich die Kugellaufrille **1a** erstreckt, so dass die Außenumfangsfläche des Schleifsteins **15** auf die Kugellaufrille **1a** übertragen wird. Gemäß einer solchen Bewegung wird ein vorstehender Abschnitt **7** zwischen der Schleifsteinposition Nr. 9 und der Schleifsteinposition Nr. 10 geformt. In dieser Fig. 8 stellt der vorstehende Abschnitt **7** eine Abmessung bereit, die größer als dessen tatsächliche Abmessung ist.

[0045] Ferner kann durch eine Linearbewegung des Schleifsteins in der Richtung, in welcher sich die Kugellaufrille **1a** erstreckt, eine Kugellaufrille für eine lineare Bewegungsführungsvorrichtung geformt werden, durch dessen Kreisbewegung eine Kugellaufrille für ein Wälzlager geformt werden, und durch dessen Spiralbewegung eine Kugellaufrille für eine Kugelumlaufspindel geformt werden.

[0046] Darüber hinaus können bei einem anderen Verfahren als dem oben erwähnten Verfahren zum Formen einer Kugellaufrille eine Mehrzahl von vorstehenden Streifen an der Kugellaufrille geformt werden, indem eine Fläche mit Vorsprüngen und Aussparungen an einer Außenumfangsfläche eines Schleifsteins unter Verwendung einer NC (Numerische Steuerung) Technologie geformt wird und dieser Schleifstein in der Erstreckungsrichtung der Kugellaufrille derart bewegt wird, dass die Außenumfangsfläche des Schleifsteins auf die Kugellaufrille übertragen wird. Ein Fräserblatt kann ersatzweise für den Schleifstein verwendet werden.

[0047] Fig. 9 zeigt eine perspektivische Ansicht einer Bewegungsführungsvorrichtung gemäß der zweiten Ausführungsform der vorliegenden Erfindung. Diese Figur zeigt eine Kugelnutung als lineare Bewegungsführungsvorrichtung. Die Kugelnutung weist eine Keilwelle **21** als ein Führungsteil und eine Außenhülse **23** als ein bewegbares Teil auf, die an der Keilwelle **21** mit einer Anzahl von dazwischen angeordneten Kugeln **22**, **22** bewegbar montiert ist.

[0048] Die Keilwelle **21** hat eine Außenfläche, in welcher Kugellaufrillen **21a**, **21a**, die als Führungsbahnen der Kugeln **22**, **22** dienen, derart ausgebildet sind, dass sie sich in der Axialrichtung der Keilwelle **21** erstrecken. Die Außenhülse **23**, die an der Keilwelle **21** montiert ist, ist an ihrer Innenumfangsfläche mit Kugellaufrillen versehen, die den Kugellaufrillen **21a**, **21a** entsprechen, die in der Keilwelle **21** ausgebildet sind, und eine Mehrzahl von vorstehenden Streifen sind in einer Richtung ausgebildet, in welcher sich die Kugellaufrillen **21a**, **21a** erstrecken.

[0049] Eine Kugellaufbahn wird zwischen den entsprechenden Kugellaufrillen gebildet, die in der Außenhülse **23** und der Keilwelle **21** ausgebildet sind. Eine unbelastete Rücklaufbahn, in welcher sich die von der Last befreiten Kugeln **22**, **22** entlang dieser Bahn bewegen, ist benachbart zu der Kugellaufbahn ausgebildet. Ein Halter **24** zum Anbringen und Halten der Kugeln **22**, **22** in Form eines Kreises ist an der Außenhülse **23** montiert.

[0050] Fig. 10 zeigt eine perspektivische Ansicht einer Kugelumlaufspindel gemäß einer dritten Ausführungsform der vorliegenden Erfindung. Die Kugelumlaufspindel weist eine Spindelwelle **31** auf, und eine Kugellaufrille **31a**, welche eine Spiralform mit einer konstanten Steigung hat und eine halbkreisförmige Querschnittsform hat, ist in einer Außenumfangsfläche der Spindelwelle **31** ausgebildet. Die Kugelumlaufspindel weist auch eine Mutter **32** auf, und eine Kugellaufrille **32a**, welche einen halbkreisförmigen Querschnitt hat, ist in einer Innenumfangsfläche der Mutter **32** derart ausgebildet, dass sie der Kugellaufrille **31a** der Spindelwelle **31** zugewandt ist. Eine Mehrzahl von vorstehenden Streifen sind an diesen Kugellaufrillen **31a** und **32a** derart ausgebildet, dass sie sich spiralförmig in der Richtung erstrecken, in welcher sich die Kugellaufrillen **31a** und **32a** erstrecken.

[0051] Eine Anzahl von Kugeln **34**, **34** sind in der Kugellaufbahn untergebracht, die von den Kugellaufrillen **31a** und **32a** der Spindelwelle **31** und der Mutter **32** gebildet wird. An der Mutter **32** sind Teile **33**, **33** für den Umlauf der Kugeln angebracht. Die Umlaufteile **33**, **33** bilden eine unbelastete Rücklaufbahn, die das eine und das andere Ende der Kugellaufrille verbindet, in welcher die Kugeln **34**, **34** in Verbindung mit der Relativbewegung der Mutter **32** in Bezug auf die Spindelwelle **31** umlaufen.

[0052] Fig. 11 zeigt eine Schnittansicht eines Radialwälzlagers gemäß der vierten Ausführungsform der vorliegenden Erfindung. Dieses Wälzlager ist mit einem Außenring **41** als ein ringförmiges Führungsteil und einem an dem Außenring **41** montierten Innenring **42** als ein ringförmiges bewegbares Teil versehen. Der Außen- und der Innenring **41** und **42** sind mit Kugellaufrillen **41a** bzw. **42a** versehen, zwischen welchen die Kugeln **43** angeordnet sind. Eine Mehrzahl von ringförmigen vorstehenden Streifen sind an Abschnitten zwischen diesen Kugellaufrillen **41a** und **42a** derart ausgebildet, dass sie sich in einer Richtung erstrecken, in welcher sich die Kugellaufrillen erstrecken. In dieser Ausführungsform können, obwohl das Radialwälzlager erwähnt ist, die Kugellaufrillen mit einer Mehrzahl von vorstehenden Streifen für ein Axialwälzlager vorgesehen sein.

[0053] Ferner ist die vorliegende Erfindung nicht auf die beschriebenen Ausführungsformen beschränkt, und viele andere Modifikationen können vorgenommen werden, ohne den Gegenstand der vorliegenden Erfindung zu verändern. Zum Beispiel ist es nicht notwendig, dass die Kugellaufrille, die mit einer Mehrzahl von vorstehenden Streifen versehen ist, sowohl an dem Führungsteil als auch an dem bewegbaren Teil ausgebildet ist, und die Kugellaufrille kann an einem dieser Teile ausgebildet sein.

[0054] Wie oben erwähnt, sind gemäß der vorliegenden Erfindung eine Mehrzahl von vorstehenden Streifen derart ausgebildet, dass sie sich in einer Richtung, in welcher sich die Kugellaufrillen erstrecken, in Abschnitten nahe der Kontaktpunkte der Kugel in den Kugellaufrillen erstrecken, um dadurch die Kugel durch die auf die Kugeln ausgeübte Belastung mit den vorstehenden Streifen in Kontakt zu bringen. Dementsprechend wird die auf die Kugel ausgeübte Belastung auf die jeweiligen Kontaktpunkte verteilt, wodurch verhindert wird, dass die Spannung auf den bestimmten einen Punkt gerichtet ist. Daher kann die Tragfähigkeit erhöht werden, ohne den Krümmungsradius der Kugellaufrille an den Radius der Kugel anzupassen.

Zusammenfassung

[0055] Bewegungsführungsvorrichtung, die geeignet ist, eine Tragfähigkeit zu erhöhen, ohne einen Krümmungsradius einer Kugellaufrille an einen Radius einer Kugel anzupassen. Die Kugellaufrillen sind in einer Führungsschiene und einem bewegbaren Block einer Linearführung als eine Führungsbahn ausgebildet, entlang welcher die zwischen der Führungsschiene und dem bewegbaren Block angeordneten Kugeln wälzen. Eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen (Rillen) sind derart ausgebildet, dass sie sich in einer Richtung, in welcher sich die Kugellaufrille erstreckt, in der Nähe von Kontaktpunkten der Kugellaufrille, in welchen die Kugel kontaktiert wird, derart erstrecken, dass die Kugel und die mehreren vorstehenden Streifen durch die auf die Kugel wirkende Belastung einander kontaktieren. Die auf die Kugel ausgeübte Belastung wird auf jeden Punkt der vorstehenden Streifen verteilt, um dadurch zu verhindern, dass eine hohe Spannung auf einen bestimmten Punkt gerichtet ist. Dementsprechend kann die Tragfähigkeit der Bewegungsführungsvorrichtung erhöht werden, ohne den Krümmungsradius der Kugellaufrille an den Radius der Kugel anzupassen.

Patentansprüche

1. Bewegungsführungsvorrichtung, aufweisend ein Führungsteil und ein bewegbares Teil, bei welcher wenigstens eines des Führungsteils und des bewegbaren Teils mit einer Kugellaufrille versehen ist, die als eine Führungsbahn zu einer Zeit wirkt, wenn eine zwischen dem Führungsteil und dem bewegbaren Teil angeordnete Kugel wälzt,
wobei eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen an der Kugellaufrille derart ausgebildet sind, dass sie sich in einer Richtung erstrecken, in welcher sich die Kugellaufrille erstreckt, und wobei die Kugel, die der Belastung zwischen dem Führungsteil und dem bewegbaren Teil ausgesetzt ist, die mehreren vorstehenden Streifen vor dem Kontaktieren ausgesparter Abschnitte zwischen den mehreren vorstehenden Streifen kontaktiert.

2. Bewegungsführungsvorrichtung gemäß Anspruch 1, wobei die vorstehenden Streifen durch die Belastung derart elastisch verformt werden, dass die Kugel die ausgesparten Abschnitte dazwischen kontaktiert.

3. Bewegungsführungsvorrichtung nach Anspruch 1 oder 2, wobei die Bewegungsführungsvorrichtung eine lineare oder gekrümmte Bewegungsführungsvorrichtung oder ein Wälzlager ist, bei welchem ein ringförmiges bewegbares Teil an einem ringförmigen Führungsteil drehbar montiert ist.

4. Kugelumlaufspindel, aufweisend eine Spindelwelle und eine Mutter, bei welcher spiralförmige Kugellaufrillen als ein Führungsteil, das zu einer Zeit wirkt, wenn eine zwischen der Spindelwelle und der Mutter angeordnete Kugel wälzt, in der Spindelwelle und der Mutter ausgebildet sind, wobei eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen in den Kugellaufrillen derart ausgebildet sind, dass sie sich in einer Richtung erstrecken, in welcher sich die Kugellaufrillen erstrecken, und wobei die Kugel, die der Belastung zwischen dem Führungsteil und dem bewegbaren Teil ausgesetzt ist, die mehreren vorste-

henden Streifen vor dem Kontaktieren ausgesparter Abschnitte zwischen den mehreren vorstehenden Streifen kontaktiert.

5. Verfahren zum Formen einer Kugellaufrille, bei welchem wenigstens eines des Führungsteils und des bewegbaren Teils mit einer Kugellaufrille als eine Führungsbahn versehen ist, die zu einer Zeit wirkt, wenn eine zwischen dem Führungsteil und dem bewegbaren Teil angeordnete Kugel wälzt, wobei das Verfahren die Schritte aufweist:
Bewegen eines scheibenförmigen Fräsers oder Schleifsteins mit einem Radius, der kleiner als jener der Kugel ist, in einer Richtung, in welcher sich die Kugellaufrille erstreckt, und Übertragen einer Außenumfangsform des scheibenförmigen Fräsers oder Schleifsteins auf die Kugellaufrille;
Bewegen des Fräsers oder Schleifsteins in einer Ebene senkrecht zu einer Richtung, in welcher sich die Kugellaufrille erstreckt; und
Bewegen des Fräsers oder Schleifsteins in der Richtung, in welcher sich die Kugellaufrille erstreckt, und Übertragen der Außenumfangsform des scheibenförmigen Fräsers oder Schleifsteins auf die Kugellaufrille,
wobei eine Mehrzahl von elastisch verformbaren, vorstehenden Streifen derart geformt werden, dass sie sich in der Richtung erstrecken, in welcher sich die Kugellaufrille erstreckt.

(54) Winkeleinstellvorrichtung

(57) Winkeleinstellvorrichtung mit einem Sockel, einem Paar Führungsteile mit einer bogenförmigen Spur, einem Schwenkkörper, der entlang der Spur der Führungsteile bewegbar ist, und einem Bewegungskörper zum Bewegen des Schwenkkörpers, um die Winkelposition des Schwenkkörpers um die Schwenkachse einzustellen. Das Bewegungsteil hat einen Motor, der im Sockel vorgesehen ist, ein Kupplungszapfen, der im Schwenkkörper vorgesehen ist, und einen Kupplungsmechanismus, der zwischen Motor und Kupplungszapfen angeordnet ist. Ein Hauptkupplungsteil des Kupplungsmechanismus ist mit einem vorderen Endabschnitt der Abtriebswelle drehbar um die Achse parallel zur Schwenkachse gekuppelt und mit dem Kupplungszapfen gekuppelt, um linear bewegbar in dessen Axialrichtung zu sein. Die Führungsteile haben zwei flache Referenzebenen und sind in einem Zustand befestigt, in dem die Referenzebenen mit zwei flachen Stellebenen des Sockels in Kontakt stehen.

DE 103 09 859 A 1

Beschreibung

[0001] Die Erfindung betrifft eine Winkeleinstellvorrichtung, eine so genannte Drehschwenkbühne (engl.: "goniostage" oder "swivel-stage").

[0002] Ein das den Stand der Technik repräsentierende Dokument über die erfindungsgemäße Winkeleinstellvorrichtung ist JP-A-2000-230548 (**Fig.** 1, **Fig.** 10). Diese Veröffentlichung offenbart eine zweiachsige Winkeleinstellvorrichtung. In einer ersten Ausführungsform dieser Vorrichtung sind eine untere Bühnenstruktur und eine obere Bühnenstruktur im wesentlichen gleich. In jeder Bühne hat die Vorrichtung einen Sockel, der einen U-förmigen Querschnitt hat, mit einer Bodenwand und zwei Seitenwänden. Der obere Rand der beiden Seitenwände des Sockels ist wie ein Kreisbogen ausgebildet und ein Führungsteil, das eine bogenförmige Form hat, ist an einer vertikalen, flachen Außenfläche (Stellebene) entlang dem oberen Rand befestigt. Das Führungsteil ist mittels einer Schraube von außen an die Seitenwand befestigt. Eine bogenförmige Nut (Spur) ist an der oberen und an der unteren Fläche des Führungsteils ausgebildet.

[0003] Außerdem weist die Vorrichtung einen Schwenkkörper in jeder Bühne auf. Der Schwenkkörper weist einen Schwenktisch, der einen U-förmigen Querschnitt hat, mit einer oberen Wand und zwei Seitenwänden und einen Durchgangsblock, der an der Innenfläche der beiden Seitenwände des Schwenktischs befestigt ist. Jeder Durchgangsblock hat eine Endlosumlaufpassage und Kugeln sind in der Endlosumlaufpassage angeordnet. Ein Teil der Endlosumlaufpassage ist einer Spur des Führungsteils zugewandt und die dazwischen angeordneten Kugeln rollen, während sie entlang der Spur des Durchgangslochs sich bewegen.

[0004] Ferner hat die Vorrichtung ein Bewegungsmittel. Dieses Bewegungsmittel bewegt den Schwenkkörper entlang der bogenförmigen Spur, um die Winkelposition des Schwenkkörpers um eine Schwenkachse (Achse verläuft durch den Krümmungsmittelpunkt der Spur) einzustellen. Das Bewegungsmittel weist einen Motor auf, der im Schwenktisch vorgesehen ist, und eine bogenförmige Zahnstange, die gemäß der ersten Ausführungsform der vorhergehenden Veröffentlichung mit einem Ritzel in Eingriff steht, wie in **Fig.** 1 gezeigt. Die Zahnstange ist nahe dem oberen Rand der Innenfläche der beiden Seitenwände des Sockels fixiert. Zusammen mit der Motordrehung wird der Schwenkkörper via den Eingriff des Ritzels und der Zahnstange entlang der Spur bewegt.

[0005] In einer vierten Ausführungsform der Veröffentlichung, wie in **Fig.** 10 gezeigt, ist das Bewegungsmittel der unteren Bühne unterschiedlich von dem der ersten Ausführungsform. Das Bewegungsmittel in der untern Bühne weist einen Motor, der im Sockel vorgesehen ist, einen Kugelgewindespindelmechanismus, der mit dem Motor gekuppelt ist, einen ersten Bewegungskörper, der linear durch den Kugelgewindespindelmechanismus horizontal bewegbar ist, und einen zweiten Bewegungskörper auf, der verschiebbar vertikal auf dem ersten Bewegungskörper vorgesehen ist. Der Schwenktisch ist drehbar mit dem zweiten Bewegungskörper gekuppelt. In dieser Ausführungsform ist der erste Bewegungskörper via den Kugelgewindespindelmechanismus zusammen mit der Motordrehung horizontal bewegbar, wobei die Horizontalbewegung via den zweiten Bewegungskörper in die Bewegung des Schwenktisch entlang der Spur umgewandelt wird.

[0006] Eine Vorrichtung gemäß JP-A-2001-99150 (**Fig.** 2, **Fig.** 4) weist wie die vorhergehende Veröffentlichung einen Sockel, ein Paar bogenförmiger Führungsteile, die am Sockel befestigt sind, einen Schwenkkörper, der entlang der Spur der Führungsteile bewegbar ist, und ein Bewegungsmittel zum Bewegen des Schwenkkörpers auf, um die Winkelposition des Schwenkkörpers um eine Schwenkachse (Achse verläuft durch den Krümmungsmittelpunkt der bogenförmigen Spur) einzustellen. Ein konvexer Abschnitt ist im Zentrum des Sockels ausgebildet und dient als eine erste Stellebene, wo beide Seitenflächen des konvexen Abschnitts vertikal sind. Eine obere Fläche, die an den konvexen Abschnitt angrenzt, ist ebenfalls eine bogenförmige Fläche, die als eine zweite Stellebene dient. Übrigens ist eine Seitenfläche des Führungsteils eine erste Referenzebene, flach, und eine bogenförmige Nut, die als Spur dient, auf der anderen Seite der Fläche ausgebildet. Außerdem ist eine untere Fläche des Führungsteils eine zweite Referenzebene, die als eine bogenförmige Fläche dient. Das Führungsteil ist am Sockel mittels einer Schraube gegen die zweite Stellebene in einem Zustand befestigt, in dem die flache erste Referenzebene des Führungsteils mit der ersten Stellebene des Sockels in Kontakt steht und die zweite Referenzebene der bogenförmigen Fläche mit der zweiten Stellebene in Kontakt steht.

[0007] Das Bewegungsmittel der Vorrichtung gemäß JP-A-2001-99150 weist einen Motor, der im Sockel vorgesehen ist, eine Schnecke, die durch den Motor gedreht wird, und einen Verzahnungsabschnitt auf, der auf dem Schwenkkörper ausgebildet ist und mit der Schnecke in Eingriff steht. Zusammen mit der Motordrehung wird der Schwenkkörper via den Eingriff der Schnecke und des Verzahnungsabschnitts gedreht.

[0008] In den letzten Jahren gibt es das Erfordernis die Feinwinkeleinstellung mit hoher Präzision auszuführen. Jedoch kann mit der herkömmlichen Winkeleinstellvorrichtung mit der Vorrichtung der vorhergehenden Veröffentlichungen dieses Erfordernis nicht erfüllt werden. Der Grund wird im folgenden erläutert.

[0009] Bei der Vorrichtung gemäß JP-A-2000-230548 wird das bogenförmige Führungsteil dann deformiert, wenn die Schraube angezogen wird, so dass sich die Rundheit der Spur verschlechtert, da das Führungsteil mittels der Schrauben in einem Zustand befestigt wird, in dem die bogenförmige, flache Referenzfläche mit der flachen Stellebene des Sockels in Kontakt ist. Bei der Vorrichtung gemäß JP-A-2001-99150 wird ebenfalls das Führungsteil deformiert und die Rundheit der Spur des Führungsteils verschlechtert, so dass die Genauigkeit der Winkelpositioneinstellung verschlechtert wird, da die zweite Referenzebene des Führungsteils mit der kreisförmigen Fläche der zweiten Stellebene des Sockels ausgerichtet ist, wenn die Rundheit des Kreisbogens der zweiten Stellebene gering ist oder die zweite Stellebene und die zweite Referenzebene einen geringfügig unterschiedlichen Krümmungsradius des Kreisbogens haben.

[0010] In der Ausführungsform gemäß JP-A-2000-230548 sind die Zahnstange und das Ritzel in jedem Schwenkkörper und im Sockel vorgesehen. In der vierten Ausführungsform ist der maßgefertigte Kugelgewindespindelmechanismus im Sockel eingebaut. In der Vorrichtung gemäß JP-A-2001-99150 sind die Schnecke und der Verzahnungsabschnitt im Sockel und im Schwenkkörper vorgesehen. Bei diesen Strukturen hat die Winkelpositioneinstellung keine hohe Genauigkeit wegen des Spiels eines nach außen freiliegenden Eingriffsabschnitts.

[0011] Durch die Erfindung wird die Aufgabe gelöst eine Winkeleinstellvorrichtung zu schaffen, mit der die Mikrowinkeleinstellungen mit hoher Genauigkeit durchgeführt werden können.

[0012] Die erfindungsgemäße Winkeleinstellvorrichtung weist auf: einen Sockel mit einer ersten und einer zweiten

Stellebene, die einander schneiden, einen Führungsteil, das am Sockel befestigt ist und einen spurausbildenden Abschnitt, eine bogenförmige Spur, die auf dem spurausbildenden Abschnitt ausgebildet ist, und einen Basisabschnitt hat, der eine erste und eine zweite Referenzebene hat, einen Schwenkkörper, der entlang der Spur des Führungsteils bewegbar ist, und ein Bewegungsteil zum Bewegen des Schwenkkörpers, um die Winkelposition des Schwenkkörpers um eine Schwenkachse einzustellen, die durch den Krümmungsmittelpunkt der Spur verläuft, wobei der spurausbildende Abschnitt und der Basisabschnitt einstückig ausgebildet sind, und das Führungsteil in einem Zustand, in dem die erste und die zweite Referenzebene mit der ersten und der zweiten Stellebene des Sockels in Kontakt sind, am Sockel befestigt ist.

[0013] Mit der vorhergehenden Konstruktion ist das Führungsteil am Sockel derart befestigt, dass die erste und die zweite flache Referenzebene des Basisabschnitts des Führungsteils mit der ersten und der zweiten flachen Stellebene des Sockels ausgerichtet sind, wobei die bogenförmige Spur nicht deformiert ist und die schlechte Rundheit der Spur vermeidbar ist. Deshalb ist die Winkeleinstellung des Schwenkkörpers bei hoher Genauigkeit durchführbar.

[0014] Bevorzugt ist das Führungsteil am Sockel befestigt, so dass die erste Referenzebene gegen die erste Stellebene durch eine erste Schraube gedrückt ist, die die erste Stellebene und die erste Referenzebene durchdringt, und am Sockel befestigt ist, so dass die zweite Referenzebene gegen die zweite Stellebene durch eine zweite Schraube gedrückt ist, die die zweite Stellebene und die zweite Referenzebene durchdringt. Dadurch ist das Positionieren des Führungsteils zuverlässiger durchführbar.

[0015] Bevorzugt hat der Sockel ein Paar Stellabschnitte, die im Abstand voneinander in Richtung parallel zur Schwenkachse angeordnet sind, wobei jeder Stellabschnitt jeweils mit der ersten und der zweiten Stellebene ausgebildet ist, wobei das Führungsteil ein Paar Führungsteile aufweist, die jeweils an einem Stellabschnitt befestigt sind, um sich einander zugewandt zu sein, wobei der spurausbildende Abschnitt jedes Führungsteils vom Basisabschnitt vorsteht, wobei der Schwenkkörper angeordnet ist, um das Paar Führungsteile quer zu überragen, wobei jeder spurausbildende Abschnitt mit einem Paar Spuren ausgebildet ist, die jeweils eine unterschiedliche Krümmung haben, wobei die Spuren im Abstand voneinander in Richtung senkrecht zur Normale der Ebene angeordnet sind, entlang der die Führungsteile einander zugeordnet sind, und wobei mindestens ein Teil des Bewegungsteils in einem Raum aufgenommen ist, der durch den Sockel, den Schwenkkörper und dem Paar Führungsteile gebildet ist.

[0016] Dadurch nimmt das Bewegungsteil keinen großen Raum in Anspruch und die Größe der Vorrichtung ist reduziert. Und der Schwenkkörper ist in Summe mittels vier Spuren stabil geführt.

[0017] Bevorzugt hat die Spur eine Rollkontaktfläche für Rollelemente, wobei der Schwenkkörper mit einer Endlosumlaufpassage ausgebildet ist, die eine Rollkontaktfläche für Rollelemente aufweist, die der Rollkontaktfläche der Spur zugewandt ist, wobei eine Mehrzahl von Rollelementen, die mit der Bewegung des Schwenkkörpers umlaufen, in der Endlosumlaufpassage angeordnet sind, und wobei die Rollelemente in einem vorgespannten Zustand zwischen der Rollelement-Rollkontaktfläche der Spur und der Rollkontaktflächen angeordnet sind. Dadurch hat der Schwenkkörper eine erhöhte Steifheit gegen das Führungsteil. Die Steifheit ist eine Größe, die die Elastizität des Versatzes oder der Deformation anzeigt, wenn eine Kraft oder ein Moment auf eine Komponente oder zwischen Komponenten wirkt, und als eine statische Steifheit und als eine dynamische Steifheit gegeben ist.

[0018] Um das vorhergehende Problem zu lösen, schaffte gemäß einem anderen Aspekt der Erfindung die Erfindung eine Winkeleinstellvorrichtung mit: einem Sockel, einem Führungsteil, das am Sockel befestigt ist und eine bogenförmige Spur aufweist, einem Schwenkkörper, der entlang der Spur des Führungsteils bewegbar ist, und einem Bewegungsteil zum Bewegen eine Schwenkkörpers, um die Winkelposition des Schwenkkörpers um die Schwenkachse einzustellen, die durch den Krümmungsmittelpunkt der Spur verläuft, wobei das Bewegungsteil aufweist: einen Antriebsabschnitt mit einer Abtriebswelle, die in Richtung senkrecht zur Schwenkachse sich erstreckt und einen einstellbaren Vorsprungsbetrag hat und im Sockel bzw. im Schwenkkörper vorgesehen ist, eine Kupplungszapfen, der im Schwenkkörper bzw. im Sockel vorgesehen ist, und einen Kupplungsmechanismus, der zwischen einem vorderen Endabschnitt der Abtriebswelle und des Kupplungszapfens angeordnet ist, um die Axialbewegung der Abtriebswelle in eine Bewegung des Schwenkkörpers entlang der Spur umzuwandeln, wobei der Kupplungsmechanismus ein Hauptkupplungsteil aufweist, das mit dem vorderen Endabschnitt der Abtriebswelle drehbar um eine Drehachse parallel zur Schwenkachse gekuppelt ist und das mit dem Kupplungszapfen gekuppelt ist, um linear bewegbar in Axialrichtung des Kupplungszapfens zu sein.

[0019] Mit der vorhergehenden Konstruktion hat der Kupplungsmechanismus keinen Eingriffsabschnitt, wie zum Beispiel eine Schraube, wodurch es ermöglicht ist eine Verschlechterung der Winkeleinstellgenauigkeit wegen Spiel zu verhindern. Eine Spannungsfeder ist ebenfalls nicht notwendig, um das Spiel abzubauen und eine hohe Lebensdauer zu erreichen.

[0020] Bevorzugt ist das Hauptkupplungsteil via einer Kugelkeilwelle mit dem Kupplungszapfen in der Art und Weise gekuppelt, dass das Hauptkupplungsteil linear bewegbar ist. Dadurch ist das Hauptkupplungsteil entlang des Kupplungszapfens stabil bewegbar.

[0021] Wenn die Abtriebswelle vorrückbar oder zurückziehbar unter Drehung ist, wobei der Kupplungsmechanismus ein Hilfskupplungsteil aufweist, das zwischen dem vorderen Endabschnitt der Abtriebswelle und dem Hauptkupplungsteil angeordnet ist, wobei das Hilfskupplungsteil mit dem vorderen Endabschnitt der Abtriebswelle gekuppelt ist, um relativ drehbar um die Längsachse der Abtriebswelle zu sein, und wobei das Hauptkupplungsteil und das Hilfskupplungsteil drehbar um die Drehachse parallel zur Schwenkachse gekuppelt sind.

[0022] Bevorzugt weist das Führungsteil ein Paar Führungsteile auf, die im Abstand voneinander angeordnet in Richtung parallel zur Schwenkachse auf dem Sockel vorgesehen sind, wobei der Schwenkkörper angeordnet ist, um das Paar Führungsteile quer zu überragen, und wobei der vordere Endabschnitt der Abtriebswelle, der Kupplungszapfen und der Kupplungsmechanismus in einem Raum angeordnet sind, der durch den Sockel, den Schwenkkörper und dem Paar Führungsteile gebildet ist. Dadurch, wenn die Abtriebswelle vorgerückt oder zurückgezogen wird, werden der linke und der rechte Abschnitt des Schwenkkörpers synchron bewegt, wobei das Auftreten von Verklemmen der linken und der rechten Spur verhindert wird.

[0023] Bevorzugt weist die Winkeleinstellvorrichtung ferner einen Winkelpositiondetektor, wobei der Winkelpositiondetektor ein Skalenaufzeichnungsteil, das im Sockel bzw. im Schwenkkörper vorgesehen ist, und einen Detektor zum Detektieren der Skala des Skalenaufzeichnungsteils auf, wobei der Detektor im Schwenkkörper bzw. im Sockel. Dadurch ist die Beziehung zwischen der abgetasteten Ausgabegröße und der Winkelposition des Schwenkkörpers linear und die Winkelposition wird direkt detektiert, woraus die Winkelpositiondetektion bei hoher Genauigkeit folgt.

[0024] Um das vorhergehende Problem zu lösen, schafft gemäß einer weiteren erfindungsgemäßen Ausführungsform die Erfindung eine Winkeleinstellvorrichtung mit: einem Sockel, einem Führungsteil, das am Sockel befestigt ist und eine bogenförmige Spur aufweist, einem Schwenkkörper, der entlang der Spur des Führungsteils bewegbar ist, und einem Bewegungsteil zum Bewegen des Schwenkkörpers, um die Winkelposition des Schwenkkörpers um eine Schwenkachse einzustellen, die durch den Krümmungsmittelpunkt der Spur verläuft, wobei das Bewegungsteil aufweist: einen Antriebsabschnitt mit einer Abtriebswelle, die in Richtung senkrecht zur Schwenkachse sich erstreckt und einen einstellbaren Vorsprungsbetrag hat und im Sockel vorgesehen ist, und ein Kupplungsmechanismus, der zwischen einem vorderen Endabschnitt der Abtriebswelle und dem Antriebsabschnitt des Schwenkkörpers angeordnet ist, um die Axialbewegung der Abtriebswelle in eine Bewegung des Schwenkkörpers entlang der Spur umzuwandeln, und wobei der Kupplungsmechanismus eine Blattfeder aufweist, wobei der Krümmungsgrad der Blattfeder verändert wird, wenn der Schwenkkörper entlang der Spur sich bewegt, um den Abstand zwischen einer Fixierposition der Blattfeder zum Schwenkkörper und der Abtriebswelle zu variieren.

[0025] Mit der vorhergehenden Konstruktion weist der Kupplungsmechanismus die Blattfeder auf und die Axialbewegung der Abtriebswelle wird via der Blattfeder in die Bewegung des Schwenkkörpers entlang der Spur umgewandelt. Deshalb hat der Kupplungsmechanismus keinen Eingriffsabschnitt, wie z. B. eine Schraube, wodurch es ermöglich ist, eine Verschlechterung der Winkeleinstellgenauigkeit wegen Spiel zu verhindern. Durch den Gebrauch der Blattfeder ist die Struktur ebenfalls vereinfacht bei niedrigen Kosten.

[0026] Wenn die Abtriebswelle vorrückbar oder zurückziehbar unter Drehung ist, wobei der Kupplungsmechanismus ein Kupplungsteil aufweist, wobei das Kupplungsteil mit dem vorderen Endabschnitt der Abtriebswelle gekuppelt ist, um relativ drehbar um die Antriebswelle zu sein, wobei ein Endabschnitt der Blattfeder am Kupplungsteil befestigt ist.

[0027] Bevorzugt weist das Führungsteil ein Paar Führungsteile auf, die auf dem Sockel im Abstand voneinander in Richtung parallel zur Schwenkachse vorgesehen sind, wobei der Schwenkkörper angeordnet ist, um das Paar Führungsteile quer zu überragen, und wobei der vordere Endabschnitt der Abtriebswelle und der Kupplungsmechanismus in einem Raum angeordnet sind, der durch den Sockel, den Schwenkkörper und dem Paar Führungsteile gebildet ist. Dadurch, wenn die Abtriebswelle vorgerückt oder zurückgezogen wird, werden der linke und der rechte Abschnitt des Schwenkkörpers synchron bewegt, wobei das Auftreten von Verklemmen der linken und der rechten Spur verhindert wird.

[0028] Im Folgenden wird die Erfindung anhand bevorzugter Ausführungsformen mit Bezugnahme auf die Zeichnungen erläutert. In der Zeichnung zeigen:

[0029] **Fig.** 1 eine Längsquerschnittsdarstellung einer Winkeleinstellvorrichtung gemäß einer erfindungsgemäßen ersten Ausführungsform,

[0030] **Fig.** 2 eine Draufsicht der Winkeleinstellvorrichtung,

[0031] **Fig.** 3 eine Draufsicht der Winkeleinstellvorrichtung, wobei ein Sockel und ein Bewegungsteil teilweise geschnitten dargestellt sind,

[0032] **Fig.** 4 eine Ansicht der Winkeleinstellvorrichtung von rechts,

[0033] **Fig.** 5 eine Ansicht der Winkeleinstellvorrichtung von rechts, wobei der Sockel, ein Bewegungsteil, ein Durchgangsblock und ein Schwenktisch der Vorrichtung in einer Explosionsdarstellung dargestellt sind,

[0034] **Fig.** 6 eine Seitenansicht der Winkeleinstellvorrichtung, wobei der Sockel, das Führungsteil und der Durchgangsblock zusammengebaut sind,

[0035] **Fig.** 7 eine Seitenansicht des Sockels und des Führungsteils, die in einer Explosionsdarstellung dargestellt ist,

[0036] **Fig.** 8 eine Seitenansicht, die teilweise ein Winkelpositiondetektiermittel der Winkeleinstellvorrichtung zeigt,

[0037] **Fig.** 9 eine Seitenansicht, die eine Glasplatte des Winkelpositiondetektiermittels zeigt,

[0038] **Fig.** 10A bis 10C Längsquerschnittsdarstellungen, die teilweise eine Winkeleinstellvorrichtung gemäß einer zweiten erfindungsgemäßen Ausführungsform zeigen, wobei in **Fig.** 10A bis 100 unterschiedliche Stellungen gezeigt sind,

[0039] **Fig.** 11 eine Längsquerschnittsdarstellung, die teilweise eine Winkeleinstellvorrichtung gemäß einer erfindungsgemäßen dritten Ausführungsform zeigt, und

[0040] **Fig.** 12 eine Längsquerschnittsdarstellung, die teilweise eine Winkeleinstellvorrichtung gemäß einer erfindungsgemäßen vierten Ausführungsform zeigt.

[0041] Unter Bezugnahme auf **Fig.** 1 bis 9 wird eine Winkeleinstellvorrichtung gemäß einer erfindungsgemäßen ersten Ausführungsform nachfolgend beschrieben. Die Winkeleinstellvorrichtung weist einen Sockel **10**, ein Paar Führungsteile **20**, die am Sockel **10** befestigt sind, einen Schwenkkörper **30**, der entlang der Führungsteile **20** geführt ist, ein Bewegungsteil **40** zum Bewegen des Schwenkkörpers **30**, und einen Detektor **50** zum Detektieren der Winkelposition des Schwenkkörpers **30** auf, wie in **Fig.** 1 bis 4 gezeigt.

[0042] Der Schwenkkörper **30** ist entlang einer kreisbogenförmigen Kurve bewegbar, was nachfolgend beschrieben wird, wobei eine Schwenkachse Ox als die Achse im Mittelpunkt der Kreisbogenkurve in **Fig.** 1 bis 4 gezeigt ist. Die Schwenkachse Ox ist senkrecht zur Zeichenfläche in **Fig.** 1, erstreckt sich jedoch von links nach rechts in **Fig.** 4. Komponenten werden nachfolgend im Detail beschrieben. Die Anordnung der Komponenten werden unter Bezugnahme auf die Schwenkachse Ox beschrieben.

[0043] Der Sockel **10** hat einen Basisabschnitt **11** mit in Form einer horizontalen Platte und einen Vorsprung **12**, der von der oberen Fläche des Basisabschnitts **10** vorsteht. Der Vorsprung **12** erstreckt sich horizontal in Richtung senkrecht zur Schwenkachse Ox, und ein konkaver Abschnitt **13**, der sich in Längsrichtung des Vorsprungs **12** erstreckt, ist an dessen oberen Fläche ausgebildet. Durchgangslöcher **14** sind an den vier Ecken des Basisabschnitts **11** ausgebildet, um die Vorrichtung an einem Fundamenttisch (nicht gezeigt) mittels Schrauben (nicht gezeigt) zu befestigen, die durch die Durchgangslöcher **14** gesteckt sind. Die Bezeichnung "Sockel" weist den Fundamenttisch auf.

[0044] Wie aus **Fig.** 3 bis 7 ersichtlich sind zwei Seiten des Vorsprungs **12** des Sockels **10** als ein Paar Stellebenen **15** vorgesehen, die flach und vertikal sind und deren Funktion nachfolgend beschrieben wird. Die oberen Flächen nahe des Vorsprungs **12** im Basisabschnitt **11** des Sockels **10** sind ebenfalls als ein Paar zweite Stellebenen **16** vorgesehen, die flach und horizontal sind. Die erste Stellebene **15** und die zweite Stellebene **16** schneiden einander senkrecht. Eine Normale der ersten Stellebene **15** ist parallel zur Schwenkachse Ox und erstreckt sich horizontal und eine Normale der zweiten Stellebene **16** ist senkrecht zur

Schwenkachse Ox und erstreckt sich vertikal. Das Paar Stellabschnitte (nahe den beiden Seiten des Vorsprungs **12**), die die Stellebenen **15** und **16** aufweisen, sind im Abstand voneinander in Richtung parallel zur Schwenkachse Ox angeordnet.

[0045] Wie aus **Fig.** 4 bis 7 ersichtlich ist das Paar Führungsteile **20** am Paar Stellabschnitte befestigt, wobei die Führungsteile **20** im Abstand voneinander in Richtung parallel zur Schwenkachse Ox und einander gegenüberliegend angeordnet sind. Jedes Führungsteil **20** hat einen Basisabschnitt **21** und einen spurausbildenden Abschnitt **22**. Der Basisabschnitt **21** hat eine Seitenfläche, die als eine erste Referenzebene **25** vorgesehen ist, die flach und vertikal ist, und eine untere Fläche, die als eine zweite Referenzebene **26** vorgesehen ist, die flach und horizontal ist. Die erste Referenzebene **25** steht in Kontakt mit der ersten Stellebene **15** des Sockels **10** und die zweite Referenzebene **26** steht in Kontakt mit der zweiten Stellebene **16** des Sockels **10**, so dass die Führungsteile **20** positioniert sind. In diesem Zustand sind die Führungsteile **20** am Sockel **10** befestigt.

[0046] Ausführlich gesehen heißt das, dass das Führungsteil **20** ein horizontales Durchgangsloch **25**a mit einem Ende hat, das offen zur ersten Referenzebene **25** ist. Der Sockel **10** hat ein Gewindeloch **15**a mit einem Ende, das offen zur Stellebene **15** ist. Durch Einsetzen einer Schraube **61** (erste Schraube) durch das Durchgangsloch **25**a von außen und Einschrauben derselben in das Gewindeloch **15**a wird das Führungsteil **20** derart befestigt, dass die erste Referenzebene **25** gegen die erste Stellebene **15** gedrückt wird. Der Sockel **10** hat ebenfalls ein vertikales Durchgangsloch **16**a mit einem Ende, das offen zur zweiten Stellebene **16** ist, und das Führungsteil **20** hat ein Gewindeloch **26**a mit einem Ende, das offen zur zweiten Referenzebene **26** ist. Durch Einsetzen einer Schraube **62** (zweite Schraube) durch das Durchgangsloch **16**a von der Unterseite und Einschrauben derselben in das Gewindeloch **26**a wird das Führungsteil **20** derart befestigt, dass die zweite Referenzebene **26** gegen die zweite Stellebene **16** gedrückt wird. Jedes Führungsteil **20** ist durch zwei (mehrere) Schrauben **61** und zwei Schrauben **62** befestigt.

[0047] Der spurausbildende Abschnitt **22** des Führungsteils **20** hat eine Kreisbogenform, steht vom vorderen Endabschnitt des Basisabschnitts **21** nach Außen vor (in Richtung weg vom Vorsprung **12** des Sockels **10** und in Richtung weg von der Seite der direkt angrenzenden Seite des Führungsteils **20**). Die Spuren **23**a und **23**b, die aus einer kreisbogenförmigen Nut bestehen, sind auf der oberen und der unteren Fläche des spurausbildenden Abschnitts **22** ausgebildet. Die Nut der Spuren **23**a und **23**b bildet eine Rollkontaktfläche von Rollelementen. Die beiden Spuren **23**a und **23**b des Spurenpaars haben unterschiedliche Krümmungsradien, jedoch haben sie den gleichen Krümmungsradiusmittelpunkt. Die Spuren **23**a und **23**b des Spurenpaars sind im Abstand voneinander in Richtung senkrecht zur Normale der Ebene angeordnet, entlang der die beiden Führungsteile **20** einander zugewandt sind.

[0048] Wie aus **Fig.** 1, 2 und 4 bis 6 ersichtlich hat der Schwenkkörper **30** einen Schwenktisch **31** und einen Durchgangsblock (Durchgangskörper) **35**. Der Schwenktisch **31** hat eine obere Wand **32**, die eben und quadratisch ist, und ein Paar Seitenwände **33**, die sich vertikal von beiden Seitenrändern der oberen Wand **32** nach unten erstrecken. Eine Normale im Mittelpunkt der oberen Fläche der oberen Wand **32** ist in **Fig.** 1 mit Lx bezeichnet. Die Normale Lx schneidet die Schwenkachse Ox. Zwei Durchgangsblöcke **35** sind durch Bolzen an die Innenseitenfläche jeder Seitenwand **33** jeweils befestigt. Jeder Durchgangsblock **35** weist eine obere und eine untere Endlosumlaufpassage **36** auf (mit einer Rollkontaktfläche für Rollelemente, die den Spuren **23**a und **23**b des Führungsteils **20** zugewandt sind).

[0049] Eine Mehrzahl von Kugeln **37** (Rollelemente) sind in der Endlosumlaufpassage **36** angeordnet, die durch die Endlosumlaufpassage **36** zusammen mit der Bewegung des Durchlaufblocks **35** umlaufen und die auf den Rollkontaktflächen zwischen dem Führungsteil **20** und dem Transitblock **35** rollen. Der Durchmesser der Kugel **37** ist geringfügig größer als das Spiel zwischen den Rollkontaktflächen. Die Rollkontaktflächen und die Kugeln **37** sind durch Einsetzen der Kugeln in die Rollkontaktflächen elastisch deformiert, wodurch die Kugeln **37** vorgespannt sind.

[0050] Das Bewegungsteil **40** wird im Folgenden beschrieben. Das Bewegungsteil **40** weist eine Antriebseinheit **42** (Antriebsabschnitt) auf, die via einer Halterung **41** am Sockel **10** befestigt ist, wie in **Fig.** 1 und 3 gezeigt. Eine Abtriebswelle **42**a der Antriebseinheit **42** erstreckt sich horizontal in Richtung senkrecht zur Schwenkachse Ox, ihr vorderer Endabschnitt tritt in einen Raum ein, der durch den Sockel **10**, den Schwenktisch **31** und dem Paar Führungsteile **20** gebildet ist. In dieser Ausführungsform ist ein Basisendabschnitt der Abtriebswelle **42**a eine Kugelgewindespindel, die mit einer Mutter (nicht gezeigt) innerhalb eines Gehäuses **42**x der Antriebseinheit **42** gepaart ist. Ein Schrittmotor (nicht gezeigt), der innerhalb des Gehäuses **42**x der Antriebseinheit **42** untergebracht ist, wird angetrieben, um die Mutter zu drehen, so dass die Abtriebswelle **42**a vorgerückt oder zurückgezogen wird, wodurch deren Vorsprungsbetrag eingestellt wird.

[0051] Ferner weist das Bewegungsteil **40** einen Kupplungszapfen **43** auf, der im Schwenkkörper **30** vorgesehen ist. Der Kupplungszapfen **43** ist im Zentrum des Schwenktischs **31** befestigt, senkrecht zur oberen Wand **32** des Schwenktischs **31** und erstreckt sich nach unten. Der Kupplungszapfen **43** ist innerhalb des Raums aufgenommen, der durch den Sockel **10**, den Schwenktisch **31** und dem Paar Führungsteile **20** gebildet ist, wobei sein vorderer Endabschnitt in den konkaven Abschnitt **13** des Sockels **10** eintritt.

[0052] Wie aus **Fig.** 1 und 3 ersichtlich ist ein Kupplungsmechanismus **45** zwischen der Abtriebswelle **42**a bzw. der Antriebseinheit **42** und dem Kupplungszapfen **43** angeordnet. Der Kupplungsmechanismus **45** hat zwei Kupplungsteile **45** und **46**. Der Basisendabschnitt des Kupplungsteils **45** ist am vorderen Endabschnitt der Abtriebswelle **42**a befestigt.

[0053] Das Kupplungsteil **45** weist ein Paar plattenähnliche Stücke an seinem vorderen Endabschnitt auf, in dem eine Welle **48** via einem Lager **47** drehbar abgestützt ist. Das Kupplungsteil (Hauptkupplungsteil) **46** hat ein Durchgangsloch **45**x, in das die Welle **48** eingesetzt und befestigt ist. Folglich ist das Kupplungsteil **46** mit dem vorderen Endabschnitt der Abtriebswelle **42** drehbar um die Welle **48** (Drehachse parallel zur Schwenkachse Ox) gekuppelt. Außerdem ist das Kupplungsteil **46** via einer zylindrischen Kugelkeilwelle **49** mit dem Kupplungszapfen **43** in Axialrichtung des Kupplungszapfens bewegbar gekuppelt, die den Kupplungszapfen **43** umschließt.

[0054] Wenn der Schrittmotor der Antriebseinheit **42** angetrieben wird, wird die Abtriebswelle **42**a axial bewegt, um dessen Vorsprungsbetrag zu ändern. Da das Kupplungsteil **46** via dem Kupplungsteil **45** mit der Abtriebswelle **42**a gekuppelt ist, um relativ drehbar aber nicht relativ axial bewegbar zu sein, wird es in die gleiche Richtung bewegt, um den Kupplungszapfen **43** zusammen mit der Axialbewegung der Abtriebswelle **42**a zu drücken. Folglich neigt sich der Kupplungszapfen **43**. Der Durchgangsblock **35** bewegt sich entlang der Spuren **23**a und **23**b der Führungsteile **20** gemäß der Neigung der Kupplungszapfen **43**, so dass der Schwenktisch **31** geneigt wird, um die Winkelposition um die Schwenkachse Ox zu ändern. Das Kupplungsteil **46** ist drehbar bezüglich der Abtriebswelle **42**a und axial bewegbar bezüglich des Kupplungszapfen **43**, wodurch die Neigung des Kupplungszapfens **43** zusammen mit der Axialbewegung der Abtriebswelle **42**a ermöglicht ist.

[0055] Der Durchgangsblock **35** wird in der Spur **23** mit den rollenden und umlaufenden Kugeln **37** geführt und unter Beschreiben eines Kreisbogens bewegt, und der Schwenktisch **31** wird unter Beschreiben des Kreisbogens geneigt. Der Mittelpunkt des Kreisbogens liegt auf der Schwenkachse Ox.

[0056] Wie aus **Fig.** 2 und 4 ersichtlich hat ein Winkelpositiondetektor **50** zum detektieren der Winkelposition des Schwenktisch **31** eine Lichtemittiereinheit **52** und eine Lichtempfangseinheit **53** (Skalendetektierteil), das via einer Halterung **51** auf dem Sockel vorgesehen ist, und eine Glasplatte **56** (Skalenaufzeichnungsteil), das via einer Halterung **55** an der Seitenwand **33** des Schwenktisch **31** vorgesehen ist. Die Lichtemittiereinheit **52** und die Lichtempfangseinheit **53** sind im Abstand voneinander in Richtung parallel zur Schwenkachse Ox angeordnet. Wie aus **Fig.** 8 ersichtlich ist die Lichtemittiereinheit **52** in vier Lichtemittieranteile **52**a aufgeteilt, nämlich obere, untere, linke und rechte Anteile, und entsprechend ist die Lichtempfangseinheit **53** ebenfalls in vier Lichtempfanganteile (nicht gezeigt) aufgeteilt, nämlich obere, unter, linke und rechte Anteile.

[0057] Die Glasplatte **56** hat einen Skalenabschnitt **56**a kreisbogenförmiger Form, der zwischen der Lichtemittiereinheit **52** und der Lichtempfangseinheit **53** angeordnet ist. Der Skalenabschnitt **56**a hat ein Skalenraster.

[0058] Ein Detektiersignal wird von der Lichtempfangseinheit **53** für jede Mikrowinkeleinheit (Skala) mit dem Wechsel der Winkelposition des Schwenktischs **31** ausgegeben. Dieses Prinzip ist bekannt und es wird auf eine detaillierte Beschreibung verzichtet. Das Winkelpositiondetektiersignal ist mit einem Mikrocomputer (nicht gezeigt) rückgekoppelt, der den Schrittmotor der Antriebseinheit **42** steuert, um die Winkeleinstellung des Schwenktischs **31** auf Basis des Detektiersignals durchzuführen.

[0059] In der Vorrichtung gemäß der vorhergehenden Konstruktion ist die erste flache Referenzebene **25** im Basisabschnitt **21** des Führungsteils **20** mit der flachen ersten Stellebene **15** des Sockels **10** ausgerichtet, und das Führungsteil **20** ist mittels den ersten Schrauben **61** an die erste Stellebene **15** unter Druck befestigt, und die zweite flache Referenzebene **26** ist mit der zweiten Stellebene **16** ausgerichtet, und das Führungsteil **20** ist mittels der Schrauben **62** an die zweite Stellebene **16** unter Druck befestigt. Deshalb werden die Spuren **23**a und **23**b kreisbogenförmiger Form nicht deformiert, wodurch es ermöglicht ist eine Verschlechterung der Rundheit der Spur **23** zu verhindern und die Winkeleinstellung des Schwenkkörpers **30** mit hoher Genauigkeit durchzuführen.

[0060] Für das Bewegungsteil **40** kann die Antriebseinheit **42** verwendet werden, die kommerziell erhältlich ist, in der der Motor und der Kugelgewindespindelmechanismus in das Gehäuse **42**x eingebaut sind. Deshalb ist es nicht notwendig den Gewindeabschnitt im Sockel **10** und im Schwenkkörper auszubilden, wodurch es ermöglicht ist eine Verschlechterung der Winkeleinstellgenauigkeit wegen Spiel zu verhindern.

[0061] Da der vordere Endabschnitt der Abtriebswelle **42**a des Bewegungsteils **40**, die Kupplungszapfen **43** und der Kupplungsmechanismus **45** im Raum aufgenommen sind, der durch den Sockel **10**, dem Paar Führungsteile **20** und dem Schwenkkörper **30** gebildet wird, ist es nicht notwendig einen großen Unterbringungsraum für das Bewegungsteil **40** vorzusehen, wodurch die Größe der Vorrichtung reduziert ist.

[0062] Wenn die Abtriebswelle **42**a, die in der Mitte angeordnet ist, vorgeschoben oder zurückgezogen wird, werden der linke und der rechte Abschnitt des Schwenkkörpers **30** synchron bewegt, wobei der linke und der rechte Abschnitt in der linken und der rechten Spur **23**a und **23**b geführt werden, wodurch ein Verklemmen der linken und der rechten Spur **23**a und **23**b verhindert wird. Außerdem wird der Schwenkkörper **30** in Summe mittels vier Spuren stabil geführt. Da die Kugeln **37** vorgespannt sind, ist die Steifheit des Schwenkkörpers **30** zum Führungsteil **20** erhöht.

[0063] Zur Winkelpositiondetektion des Schwenkkörpers **30** wird die Lichtempfangseinheit **53**, die auf dem Sockel **10** vorgesehen ist, mit einer Skala der Glasplatte **56**, die auf dem Schwenkkörper **30** vorgesehen ist, verwendet, wodurch die Beziehung zwischen der detektierten Ausgabegröße und der Winkelposition des Schwenkkörpers **30** linear sein kann und die Winkelposition direkt detektiert werden kann (d. h. die Winkelposition wird nicht indirekt aus der Anzahl von Ausgabeschritten des Schrittmotors der Antriebseinheit **42** berechnet), so dass die Winkelposition mit hoher Genauigkeit detektiert wird. Und die Nullpunkteinstellung ist möglich.

[0064] Unter Bezugnahme auf **Fig.** 10 bis 12 werden andere Ausführungsformen im Folgenden beschrieben. Diese Ausführungsformen haben die gleiche Grundkonstruktion wie die erste Ausführungsform, es werden im Folgenden nur unterschiedliche Teile beschrieben. Die vergleichbaren Teile sind mit denselben Bezugszeichen bezeichnet und werden nicht beschrieben.

[0065] **Fig.** 10 zeigt eine erfindungsgemäße zweite Ausführungsform. In dieser Ausführungsform führt der konkave Abschnitt **13** zur Seite der Antriebseinheit **42**, der im Vorsprung **12** des Sockels **10** ausgebildet ist. Ein Kupplungsmechanismus **80**, der unterschiedlich von dem der ersten Ausführungsform ist, ist zwischen dem vorderen Endabschnitt der Abtriebswelle **42**a der Antriebseinheit **42** und dem Schwenktisch **31** angeordnet.

[0066] Der Kupplungsmechanismus **80** wird im Folgenden beschrieben. Ein Kupplungsteil **81** ist am vorderen Endabschnitt der Abtriebswelle **42**a befestigt und eine Halterung **82** ist am Kupplungsteil **81** befestigt. Die obere Fläche der Halterung **82** ist eine Anbringfläche **82**a, die horizontal und parallel zur Längsachse der Abtriebswelle **42**a ist. Auf der Anbringfläche **82**a ist das eine Ende einer breiten Blattfeder **83** befestigt, die sich in Längsrichtung der Abtriebswelle **42**a erstreckt. Andererseits ist ein konvexer Abschnitt **84** auf der unteren Fläche der oberen Wand **42** des Schwenktischs **31** ausgebildet. Die untere Fläche des konvexen Abschnitts **84** ist eine geneigte Anbringfläche **84**a, an der das andere Ende der Blattfeder **83** befestigt ist. Eine Plattenfläche der Blattfeder **83** ist dem Schwenktisch **31** zugewandt, und die andere Plattenfläche der Blattfeder **83** ist dem Sockel **10** zugewandt.

[0067] Die Blattfeder **83** hat eine gekrümmte Form in einem Zustand (Horizontalzustand), in dem der Schwenktisch **31** parallel zum Sockel **10** ist, wie in **Fig.** 10A gezeigt. Wenn die Abtriebswelle **42**a mittels des Schrittmotors der Antriebseinheit **42** axial bewegt wird, wird die Schwenkeinheit via der Blattfeder **83** entlang der kreisbogenförmigen Spur **30** bewegt. Da die Blattfeder **83** aus einer SUS-Stahlplatte hergestellt und breit ist, hat die Blattfeder **83** eine genügend hohe Steifheit, wodurch die Umwandlung der Bewegung ermöglicht ist.

[0068] Wenn die Abtriebswelle **42**a vorgerückt wird, um den Vorsprungsbetrag zu erhöhen, wie in **Fig.** 10B gezeigt, wird der Schwenktisch **31** bewegt, um nach rechts geneigt zu werden, so dass ein Fixierabschnitt der Blattfeder **83** auf dem Schwenktisch **31** nach oben verlagert wird, wodurch der Abstand vom Vorsprung der Abtriebswelle **42**a vergrößert wird. Die Verlagerung des Fixierabschnitts der Blattfeder **83** nach oben ist wegen einer Erhöhung des Krümmungsgrads der Blattfeder **83** ermöglicht.

[0069] Wenn die Abtriebswelle **42**a zurückgezogen wird, um den Vorsprungsbetrag zu verkleinern, wie in **Fig.** 10C gezeigt, wird der Schwenktisch **31** bewegt, um nach links geneigt zu werden, so dass ein Fixierabschnitt der Blattfeder **83** auf dem Schwenktisch **31** nach unten verlagert wird, wodurch der Abstand vom Vorsprung der Abtriebswelle **42**a verkleinert wird. Die Verlagerung des Fixierabschnitts der Blattfeder **83** nach unten ist wegen einer Erhöhung des Krümmungsgrads der Blattfeder **83** ermöglicht. In der zweiten Ausführungsform ist die Blattfeder **83** innerhalb des Winkeleinstellbereichs des Schwenktischs **31** stets gekrümmt. D. h., die Blattfeder **83** ist leicht gekrümmt, sogar wenn der Vorsprungsbetrag der Abtriebswelle **42**a am kleinsten ist.

[0070] In der zweiten Ausführungsform ist eine Ausbildung des Gewindeabschnitts im Sockel **10** und im Schwenkkörper **30** nicht notwendig, wodurch es ermöglicht ist, eine Verschlechterung der Winkeleinstellgenauigkeit wegen Spiel zu vermeiden. Die Verwendung der Blattfeder **83**, des Lagers **47** und der Kugelkeilwelle **49** in der ersten Ausführungsform ist vermeidbar, um eine einfache und kostengünstige Struktur zu erhalten.

[0071] Gemäß einer erfindungsgemäßen dritten Ausführungsform, wie in **Fig.** 11 gezeigt, wird eine Mikroschraube **70**, die manuell betätigbar ist, als der Antriebsabschnitt verwendet. Eine Abtriebswelle **70**a der Mikroschraube **70** hat ein Kupplungsteil **45**a, das koaxial an der Abtriebswelle **70**a befestigt ist. Am vorderen Endabschnitt mit kleinerem Durchmesser des Kupplungsteils **45**a ist ein Kupplungsteil **45**b (Hilfskupplungsteil), das einen zylindrischen Basisendabschnitt hat, via einem Lager **90** drehbar gekuppelt. Der Drehmittelpunkt des Kupplungsteils **45**b fällt mit der Längsachse der Abtriebswelle **70**a zusammen. Die Kupplungsteile **45**a und **45**b sind relativ in Axialrichtung der Abtriebswelle **70**a unbeweglich. Am vorderen Endabschnitt des Kupplungsteils **45**b ist das Kupplungsteil **46** via dem Lager **47** und der Welle **48** wie gemäß der ersten Ausführungsform gekuppelt.

[0072] Da das Kupplungsteil **45**b via dem Kupplungsteil **45**a mit der Abtriebswelle **70**a gekuppelt ist, um relativ drehbar zu sein, jedoch um relativ axial unbeweglich zu sein, wird es axial bewegt, indem es der Axialbewegung der Abtriebswelle **70**a unter Drehung folgt, um den Schwenktisch **31** via dem Kupplungsteil **46** und dem Kupplungszapfen **43** zu neigen.

[0073] Gemäß einer vierten Ausführungsform, wie in **Fig.** 12 gezeigt, ist eine Blattfeder **83** gemäß der zweiten Ausführungsform und die Mikroschraube **70**, die manuell betätigbar ist, verwendet. Der vordere Endabschnitt der Abtriebswelle **70**a der Mikroschraube **70** ist via den Kupplungsteilen **45**a und **45**b und den Lager **70** mit der Halterung **82** gekuppelt. Der restliche Aufbau und die Funktion sind gleich wie gemäß der dritten Ausführungsform.

[0074] Es ist bevorzugt, dass der Befestigungsabschnitt der Blattfeder **83** zur Welle **70**a fast auf dem Vorsprung der Welle **70**a angeordnet ist, oder darüber (mehr am Schwenktisch **31**) wie gemäß der zweiten Ausführungsform. Gemäß dieser Art und Weise ist es ausreichend, dass die Blattfeder **83** eine geringere elastische Deformierbarkeit und eine kleinere elastische Rückstellkraft hat, die vom Antriebsabschnitt aufgenommen wird.

[0075] Gemäß einer weiteren erfindungsgemäßen Ausführungsform kann die Abtriebswelle ein Antriebsabschnitt eines Motors sein, die vorrückbar oder zurückziehbar unter Drehung ist, oder kann eine Mikroschraube sein, die manuell betätigbar und vorrückbar oder zurückziehbar ohne Drehung ist. Im Gegensatz zu den vorhergehenden Ausführungsformen kann der Antriebsabschnitt auf dem Schwenktisch vorgesehen sein und die Kupplungszapfen könnte auf dem Sockel vorgesehen sein. Der Winkelpositiondetektor ist nicht auf den optischen Detektor beschränkt, er kann ein magnetischer Detektor sein.

[0076] Die Erfindung könnte bei einer zweiachsen Winkeleinstellvorrichtung angewendet werden. In diesem Fall sind die obere und die untere Bühne gemäß den vorhergehenden Ausführungsformen konstituiert, wobei der Sockel **10** in der oberen Bühne am Schwenktisch **31** in der unteren Bühne befestigt ist. Der Schwenktisch in der oberen Bühne und der Sockel in der unteren Bühne können einstückig ausgebildet sein.

[0077] Wie vorgehend beschrieben, kann erfindungsgemäß die Mikrowinkelpositioneinstellung bei hoher Genauigkeit durchgeführt werden.

Patentansprüche

1. Winkeleinstellvorrichtung mit:
einem Sockel (**10**) mit einer ersten und einer zweiten Stellebene (**15**, **16**), die einander schneiden,
einem Führungsteil (**20**), das am Sockel (**10**) befestigt ist und einen spurausbildenden Abschnitt (**22**), eine bogenförmige Spur (**23**a, **23**b), die auf dem spurausbildenden Abschnitt (**22**) ausgebildet ist, und einen Basisabschnitt (**21**) hat, der eine erste und eine zweite Referenzebene hat (**25**, **26**)
einem Schwenkkörper (**30**), der entlang der Spur (**23**a, **23**b) des Führungsteils (**20**) bewegbar ist, und
einem Bewegungsteil (**40**) zum Bewegen des Schwenkkörpers (**30**), um die Winkelposition des Schwenkkörpers (**30**) um eine Schwenkachse (Ox) einzustellen, die durch den Krümmungsmittelpunkt der Spur (**23**a, **23**b) verläuft, wobei der spurausbildende Abschnitt (**22**) und der Basisabschnitt (**21**) einstückig ausgebildet sind, und das Führungsteil (**20**) in einem Zustand, in dem die erste und die zweite Referenzebene (**25**, **26**) mit der ersten und der zweiten Stellebene (**15**, **16**) des Sockels (**10**) in Kontakt sind, am Sockel (**10**) befestigt ist.

2. Winkeleinstellvorrichtung gemäß Anspruch 1, wobei das Führungsteil (**20**) am Sockel (**10**) befestigt ist, so dass die erste Referenzebene (**25**) gegen die erste Stellebene (**15**) durch eine erste Schraube (**61**) gedrückt ist, die die erste Stellebene (**15**) und die erste Referenzebene (**25**) durchdringt, und am Sockel (**10**) befestigt ist, so dass die zweite Referenzebene (**26**) gegen die zweite Stellebene (**16**) durch eine zweite Schraube (**62**) gedrückt ist, die die zweite Stellebene (**16**) und die zweite Referenzebene (**26**) durchdringt.

3. Winkeleinstellvorrichtung gemäß Anspruch 1, wobei der Sockel (**10**) ein Paar Stellabschnitte hat, die im Abstand voneinander in Richtung parallel zur Schwenkachse (Ox) angeordnet sind, wobei jeder Stellabschnitt jeweils mit der ersten und der zweiten Stellebene (**15**, **16**) ausgebildet ist, wobei
das Führungsteil (**20**) ein Paar Führungsteile (**20**) aufweist, die jeweils an einem Stellabschnitt befestigt sind, um einander zugewandt zu sein, wobei
der spurausbildende Abschnitt (**22**) jedes Führungsteils (**20**) vom Basisabschnitt (**21**) vorsteht, wobei
der Schwenkkörper (**30**) angeordnet ist, um das Paar

Führungsteile (**20**) quer zu überragen, wobei
jeder spurausbildende Abschnitt (**22**) mit einem Paar Spuren (**23**a, **23**b) ausgebildet ist, die jeweils eine unterschiedliche Krümmung haben, wobei die Spuren (**23**a, **23**b) im Abstand voneinander in Richtung senkrecht zur Normale der Ebene angeordnet sind, entlang der die Führungsteile (**20**) einander zugeordnet sind, und wobei
mindestens ein Teil des Bewegungsteils in einem Raum aufgenommen ist, der durch den Sockel (**10**), den Schwenkkörper (**30**) und dem Paar Führungsteile (**20**) gebildet ist.
4. Winkeleinstellvorrichtung gemäß Anspruch 1, wobei die Spur (**23**a, **23**b) eine Rollkontaktfläche für Rollelemente (**37**) hat, wobei
der Schwenkkörper (**30**) mit einer Endlosumlaufpassage (**36**) ausgebildet ist, die eine Rollkontaktfläche für Rollelemente (**37**) aufweist, die der Rollkontaktfläche der Spur (**23**a, **23**b) zugewandt ist, wobei
eine Mehrzahl von Rollelementen (**37**), die mit der Bewegung des Schwenkkörpers (**30**) umlaufen, in der Endlosumlaufpassage (**36**) angeordnet sind, und wobei die Rollelemente (**37**) in einem vorgespannten Zustand zwischen der Rollelement-Rollkontaktfläche der Spur (**23**a, **23**b) und der Rollkontaktflächen angeordnet sind.
5. Winkeleinstellvorrichtung mit:
einem Sockel (**10**),
einem Führungsteil (**20**), das am Sockel (**10**) befestigt ist und eine bogenförmige Spur (**23**a, **23**b) aufweist,
einem Schwenkkörper (**30**), der entlang der Spur (**23**a, **23**b) des Führungsteils (**20**) bewegbar ist, und
einem Bewegungsteil (**40**) zum Bewegen eines Schwenkkörpers (**30**), um die Winkelposition des Schwenkkörpers (**30**) um die Schwenkachse (Ox) einzustellen, die durch den Krümmungsmittelpunkt der Spur (**23**a, **23**b) verläuft, wobei das Bewegungsteil (**40**) aufweist:
einen Antriebsabschnitt (**42**) mit einer Abtriebswelle (**42**a), die in Richtung senkrecht zur Schwenkachse (Ox) sich erstreckt und einen einstellbaren Vorsprungsbetrag hat und im Sockel (**10**) bzw. im Schwenkkörper (**30**) vorgesehen ist,
einen Kupplungszapfen (**43**), der im Schwenkkörper (**30**) bzw. im Sockel (**10**) vorgesehen ist, und
einen Kupplungsmechanismus (**45**), der zwischen einem vorderen Endabschnitt der Abtriebswelle und des Kupplungszapfens angeordnet ist, um die Axialbewegung der Abtriebswelle in eine Bewegung des Schwenkkörpers entlang der Spur umzuwandeln, wobei
der Kupplungsmechanismus ein Hauptkupplungsteil aufweist, das mit dem vorderen Endabschnitt der Abtriebswelle (**42**a) drehbar um eine Drehachse parallel zur Schwenkachse (Ox) gekuppelt ist und das mit dem Kupplungszapfen (**43**) gekuppelt ist, um linear bewegbar in Axialrichtung des Kupplungszapfens (**43**) zu sein.
6. Winkeleinstellvorrichtung gemäß Anspruch 5, wobei das Hauptkupplungsteil (**46**) via einer Kugelkeilwelle mit dem Kupplungszapfen (**43**) in der Art und Weise gekuppelt ist, dass das Hauptkupplungsteil (**46**) linear bewegbar ist.
7. Winkeleinstellvorrichtung gemäß Anspruch 5, wobei die Abtriebswelle (**42**a) vorrückbar oder zurückziehbar unter Drehung ist,
wobei der Kupplungsmechanismus (**45**) ein Hilfskupplungsteil (**45**b) aufweist, das zwischen dem vorderen Endabschnitt der Abtriebswelle (**42**a) und dem Hauptkupplungsteil (**46**) angeordnet ist, wobei das Hilfskupplungsteil (**45**a) mit dem vorderen Endabschnitt der Abtriebswelle (**42**a) gekuppelt ist, um relativ drehbar um die Längsachse der Abtriebswelle (**42**a) zu sein, und wobei
das Hauptkupplungsteil (**46**) und das Hilfskupplungsteil (**45**b) drehbar um die Drehachse parallel zur Schwenkachse (Ox) gekuppelt sind.
8. Winkeleinstellvorrichtung gemäß Anspruch 5, wobei das Führungsteil (**20**) ein Paar Führungsteile (**20**) aufweist, die im Abstand voneinander angeordnet in Richtung parallel zur Schwenkachse (Ox) auf dem Sockel (**10**) vorgesehen sind, wobei der Schwenkkörper (**30**) angeordnet ist, um das Paar Führungsteile (**20**) quer zu überragen, und wobei der vordere Endabschnitt der Abtriebswelle (**42**a), der Kupplungszapfen (**43**) und der Kupplungsmechanismus (**45**) in einem Raum angeordnet sind, der durch den Sockel (**10**), den Schwenkkörper (**30**) und dem Paar Führungsteile (**20**) gebildet ist.
9. Winkeleinstellvorrichtung gemäß Anspruch 5, mit einem Winkelpositiondetektor (**50**), wobei der Winkelpositiondetektor (**50**) ein Skalenaufzeichnungsteil (**56**), das im Sockel (**10**) bzw. im Schwenkkörper (**30**) vorgesehen ist, und einem Detektor (**50**) zum Detektieren der Skala des Skalenaufzeichnungsteils (**56**) aufweist, wobei der Detektor (**50**) im Schwenkkörper (**30**) bzw. im Sockel (**10**) vorgesehen ist.
10. Winkeleinstellvorrichtung mit:
einem Sockel (**10**),
einem Führungsteil (**20**), das am Sockel (**10**) befestigt ist und eine bogenförmige Spur (**23**a, **23**b) aufweist,
einem Schwenkkörper (**30**), der entlang der Spur (**23**a, **23**b) des Führungsteils (**20**) bewegbar ist, und
einem Bewegungsteil (**40**) zum Bewegen des Schwenkkörpers (**30**), um die Winkelposition des Schwenkkörpers (**30**) um eine Schwenkachse (Ox) einzustellen, die durch den Krümmungsmittelpunkt der Spur (**23**a, **23**b) verläuft, wobei das Bewegungsteil (**40**) aufweist:
einen Antriebsabschnitt (**42**) mit einer Abtriebswelle (**42**a), die in Richtung senkrecht zur Schwenkachse (Ox) sich erstreckt und einen einstellbaren Vorsprungsbetrag hat und im Sockel (**10**) vorgesehen ist, und
ein Kupplungsmechanismus (**80**), der zwischen einem vorderen Endabschnitt der Abtriebswelle (**42**a) und dem Antriebsabschnitt (**42**) des Schwenkkörpers (**30**) angeordnet ist, um die Axialbewegung der Abtriebswelle (**42**a) in eine Bewegung des Schwenkkörpers (**30**) entlang der Spur (**23**a, **23**b) umzuwandeln, und wobei der Kupplungsmechanismus (**80**) eine Blattfeder (**83**) aufweist, wobei der Krümmungsgrad der Blattfeder (**83**) verändert wird, wenn der Schwenkkörper (**30**) entlang der Spur (**23**a, **23**b) sich bewegt, um den Abstand zwischen einer Fixierposition der Blattfeder (**83**) zum Schwenkkörper (**30**) und der Abtriebswelle (**42**a) zu variieren.
11. Winkeleinstellvorrichtung gemäß Anspruch 10, wobei die Abtriebswelle vorrückbar oder zurückziehbar unter Drehung ist, wobei der Kupplungsmechanismus (**80**) ein Kupplungsteil (**45**a) aufweist, wobei das Kupplungsteil (**45**a) mit dem vorderen Endabschnitt der Abtriebswelle (**42**a) gekuppelt ist, um relativ drehbar um die Antriebswelle (**42**a) zu sein, wobei ein Endabschnitt der Blattfeder (**83**) am Kupplungsteil (**45**a) befestigt ist.
12. Winkeleinstellvorrichtung gemäß Anspruch 10, wobei das Führungsteil (**20**) ein Paar Führungsteile

(**20**) aufweist, die auf dem Sockel (**10**) im Abstand voneinander in Richtung parallel zur Schwenkachse (Ox) vorgesehen sind, wobei der Schwenkkörper (**30**) angeordnet ist, um das Paar Führungsteile (**20**) quer zu überragen, und wobei der vordere Endabschnitt der Abtriebswelle (**42**a) und der Kupplungsmechanismus (**80**) in einem Raum angeordnet sind, der durch den Sockel (**10**), den Schwenkkörper (**30**) und dem Paar Führungsteile (**20**) gebildet ist.

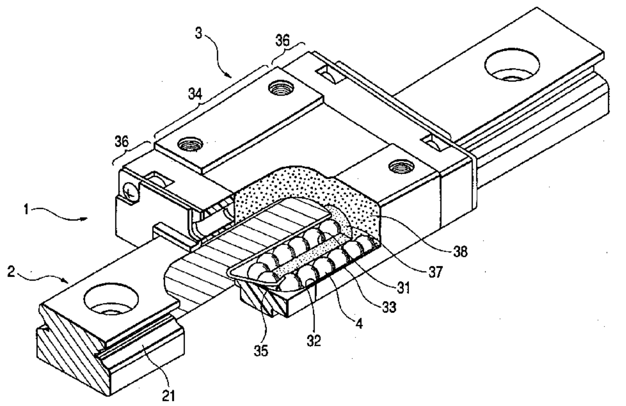
Die folgenden Angaben sind den vom Anmelder eingereichten Unterlagen entnommen

(54) Bezeichnung: **Wälzführungsvorrichtung**

(57) Zusammenfassung: Eine Wälzführungsvorrichtung umfasst einen Laufschaft, auf dem eine Wälzelementabwälzoberfläche in einer Längsrichtung davon ausgebildet ist, und ein Gleittisch mit einem endlosen Zirkulationskanal. Der endlose Zirkulationskanal umfasst eine Lastabwälzooberfläche entsprechend der Wälzelementabwälzoberfläche. Mehrere Wälzelemente sind in dem endlosen Zirkulationskanal aufgenommen. Der Gleittisch hat eine Gleittischhaupteinheit und Seitenabdeckungen, die an den entsprechenden Enden der Gleittischhaupteinheit angebracht sind. Die Gleittischhaupteinheit weist einen Lastabwälzooberflächenabschnitt, der die Lastabwälzoberfläche aufweist, und einen Hauptkörperabschnitt auf. Der Lastabwälzoberflächenabschnitt ist aus technischer Keramik hergestellt. Der Hauptkörperabschnitt ist aus bearbeitbarer Keramik hergestellt.



Beschreibung

HINTERGRUND DER ERFINDUNG 1. Gebiet der Erfindung

[0001] Die vorliegende Erfindung bezieht sich auf eine Wälzführungsvorrichtung mit leichtem Gewicht und hoher Festigkeit, welcher für lineare Führungsvorrichtungen, wie zum Beispiel eine Werkzeugmaschine oder einen X-Y-Tisch verwendbar sind.

Stand der Technik

2. Beschreibung des Stand der Technik

[0002] Eine Wälzführungsvorrichtung, die in einer Werkzeugmaschine oder ähnlichem eingebaut ist und einen Tisch zum Aufnehmen eines Werkstücks führt, umfasst einen Laufschaft, in dem eine Wälzelementabwälzoberfläche in einer Längsrichtung davon ausgebildet ist; und einen Gleittisch, der einen endlosen Zirkulationskanal umfassend einer Lastabwälzoberfläche entsprechend der Wälzelementabwälzoberfläche aufweist, und der an dem Laufschaft über mehrere Wälzelemente angebracht ist, die in dem endlosen Zirkulationskanal aufgenommen sind. Der Laufschaft und der Gleittisch sind relativ zueinander mittels der Wälzelemente beweglich.

[0003] Der Gleittisch umfasst einen Gleittischhauptkörper, in dem die Lastabwälzoberfläche und ein Wälzelementrückführkanal im wesentlichen parallel zu der Lastabwälzoberfläche ausgebildet sind; und Seitenabdeckungen, in denen Richtungsumkehrkanäle zum Verbinden beider Enden des Lastabwälzkanals und der Wälzelementrückführkanäle vorgesehen sind, und welche an den entsprechenden Enden des Gleittischhauptkörpers angebracht sind.

[0004] Nachforschungen auf dem Gebiet derartiger Wälzführungsvorrichtungen wurden durchgeführt mit der Absicht den Gleittisch leichter zu gestalten, die Massenkraft zu reduzieren und Hochgeschwindigkeits-Start- und Stoppvorgänge zu ermöglichen. Wälzführungsvorrichtungen, wie sie in den japanischen Patentanmeldungen mit den Veröffentlichungsnummern 219520/1984 und 219153/1996 beschrieben sind, haben eine Gleittischhaupteinheit, wobei die Gleittischhaupteinheit mit Ausnahme einer Lastabwälzoberfläche aus Kunstharz hergestellt ist.

[0005] Nachforschungen auf dem Gebiet der Lastabwälzoberflächen von Gleittischhauptkörpern wurden durchgeführt, um die Abwälzzeitfestigkeit und um die Abriebfestigkeit der Wälzelemente zu verbessern. Die japanische Patentanmeldung mit der Veröffentlichungsnummer 325414/1998 offenbart ein Formen der Führungsoberflächen eines Gleittisches oder des gesamten Gleittisches aus einer Keramik, um die Erzeugung von Abnutzungen zu verhindern, welche andererseits verursacht würde, wenn die Wälzelemente mit der Wälzelementabwälzoberfläche in Verbindung kommen.

[0006] Nachfrage besteht für eine Gleittischhaupteinheit mit herausragenden mechanischen Eigenschaften, wie z.B. Biegesteifigkeit, und welche leicht maschinell herstellbar ist. Eine Gleittischhaupteinheit, die bis auf die Lastabwälzoberfläche aus Kunstharz hergestellt ist, ist leicht maschinell herstellbar, weist aber nicht unbedingt herausragenden mechanische Eigenschaften auf.

[0007] Auch in dem Fall, in dem die Lastabwälzoberfläche aus Keramik hergestellt ist, um die Erzeugung von Abnutzungen zu verhindern, ist die Abwälzzeitfestigkeit und die Abriebfestigkeit der Wälzelemente nicht ausreichend.

Aufgabenstellung

ZUSAMMENFASSUNG DER ERFINDUNG

[0008] Die vorliegende Erfindung schlägt eine Wälzführungsvorrichtung vor, die für eine lineare Führungsvorrichtung wie z.B. eine Werkzeugmaschine oder einen X-Y-Tisch verwendbar ist, und insbesondere eine Wälzführungsvorrichtung, die ein leichtes Gewicht und eine hohe Festigkeit aufweist, was durch einen Verbund aus Keramikausgangsmaterial erreicht wird.

[0009] Gemäß einem ersten Aspekt der vorliegenden Erfindung ist eine Wälzführungsvorrichtung vorgeschlagen, umfassend ein Laufschaft mit einer Wälzelementabwälzoberfläche, die in einer Längsrichtung davon ausgebildet ist; ein Gleittisch mit einem endlosen Zirkulationskanal umfassend einer Lastabwälzoberfläche entsprechend der Wälzelementabwälzoberfläche, wobei der Gleittisch relativ zu dem Laufschaft bewegbar ist; und mehrere Wälzelemente, die in dem endlosen Zirkulationskanal untergebracht sind, um entsprechend der Relativbewegung des Laufschafts und des Gleittisches zu zirkulieren, wobei der Gleittisch umfasst: eine Gleittischhaupteinheit mit der Lastabwälzoberfläche und einem im wesentlichen parallel zu der Lastabwälzoberfläche vorgesehenen Wälzelementrückführkanal; und Seitenabdeckungen, die jeweils einen Richtungsumkehrkanal zum Verbinden der Enden der Lastabwälzoberfläche und des Abwälzelementrückführkanals aufweisen, wobei die Seitenabdeckungen an den entsprechenden Enden der Gleittischhaupteinheit angebracht sind, und wobei die Gleittischhaupteinheit umfasst: einen Lastabwälzoberflächenabschnitt hergestellt aus technischer Keramik, und umfassend der Lastabwälzoberfläche; und ein Hauptkörperabschnitt hergestellt aus bearbeitbarer Keramik.

[0010] Gemäß dem ersten Aspekt ist der Lastabwälzoberflächenabschnitt mit der Lastabwälzoberfläche aus technischer Keramik hergestellt, die eine herausragende Abwälzzeitfestigkeit und eine herausragende Abriebsbeständigkeit aufweist. Der Hauptkörperabschnitt, welcher der restliche Abschnitt der Gleittischhaupteinheit ist, ist aus bearbeitbarer Keramik hergestellt, die herausragenden mechanische Eigenschaften aufweist und leicht zu bearbeiten ist. Folglich erfüllt die Gleittischhaupteinheit die Eigenschaften, die bisher erforderlich waren und erfüllt die Anforderungen an die Gewichtsreduzierung und hohe Festigkeit. Folglich sind Hochgeschwindigkeits-Start- und Stoppvorgänge mit kleiner Massenkraft realisierbar.

[0011] Gemäß einem zweiten Aspekt der Erfindung umfasst die Wälzführungsvorrichtung ferner eine Laufgehäusenut, die in dem Hauptkörperabschnitt ausgebildet ist; und einen Laufring, der als Lastabwälzoberflächenabschnitt dient, welcher Laufring in die Laufgehäusenut eingepasst ist.

[0012] Gemäß dem zweiten Aspekt kann die Laufgehäusenut leicht in dem Hauptkörperabschnitt, der aus bearbeitbarer Keramik mit einer leichten Bearbeitbarkeit hergestellt ist, gebildet werden. Folglich kann ein Laufring, der eine herausragende Abwälzzeitfestigkeit aufweist und als ein Lastabwälzoberflächenabschnitt wirkt, leicht in die Laufgehäusenut eingepasst werden. Der Laufring ist aus technischer Keramik hergestellt und weist eine herausragende Abwälzzeitfestigkeit auf. Folglich kann eine langlebige Wälzführungsvorrichtung realisiert werden.

[0013] Gemäß einem dritten Aspekt der vorliegenden Erfindung haben die Laufgehäusenut und der Laufring halbkreisförmige Querschnittsprofile, die komplement zueinander sind, welcher Laufring in Bezug auf die Laufgehäusenut drehbar ist.

[0014] Gemäß dem dritten Aspekt haben die Laufgehäusenut und der Laufring halbkreisförmige Querschnittsprofile, die komplement zueinander sind und die Laufgehäusenut und der Laufring sind derart ausgebildet, dass sie drehbar sind. Folglich kann ein Selbstausrichtungsvorgang realisiert werden.

Ausführungsbeispiel

[0015] **Fig.** 1 ist eine teilweise aufgebrochene perspektivische Ansicht, die ein Beispiel einer Wälzführungsvorrichtung der Erfindung zeigt;

GENAUE BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSFORMEN

[0021] Eine Wälzführungsvorrichtung der Erfindung wird unter Bezugnahme auf die begleitenden Zeichnungen im folgenden beschrieben.

[0022] Eine Wälzführungsvorrichtung **1**, wie in **Fig.** 1 dargestellt, umfasst eine Schiene **2**, auf der eine Wälzelementabwälzoberfläche **21** in einer Längsrichtung ausgebildet ist, und die als Laufschaft dient; einen Block **3**, der einen endlosen Zirkulationskanal **32** umfassend einer Lastabwälzoberfläche **31** entsprechend der Wälzelementabwälzoberfläche **21** aufweist und der als relativ zu der Schiene **2** beweglicher Gleittisch dient; und mehreren Wälzelementen **4**, die in dem endlosen Zirkulationskanal **32** aufgenommen sind und entsprechend der Relativbewegung, die zwischen der Schiene **2** und dem Block auftritt, zirkulieren.

[0023] Der Block **3** umfasst einen Gleittischhauptkörper (im folgenden als "Blockhaupteinheit **34**" bezeichnet) in dem die Lastabwälzoberfläche **31** und ein im wesentlichen parallel zu der Lastabwälzoberfläche **32** vorgesehener Wälzelementrückführkanal **33** ausgebildet sind; und Seitenabdeckungen **36**, die an den entsprechenden Enden der Blockhaupteinheit **34** angebracht sind. In jeder der Seitenabdeckungen ist ein Richtungsumkehrkanal **35** ausgebildet zum Verbinden der Enden der Lastabwälzoberflächen **31** und der Wälzelementrückführkanäle **33**.

[0024] Die Blockhaupteinheit **34** weist einen Lastabwälzoberflächenabschnitt **37**, der die Lastabwälzoberfläche **31** aufweist und aus technischer Keramik hergestellt ist; und ein Hauptkörperabschnitt **38** hergestellt aus bearbeitbarer Keramik auf.

[0025] Die Wälzführungsvorrichtung **1** ist nicht auf einen speziellen Typ begrenzt und kann eine Schiene **2** der linearen Art, wie in **Fig.** 1 dargestellt oder eine Schiene der gekrümmten Art aufweisen. Die Wälzelemente sind nicht auf Wälzelemente einer bestimmten Art begrenzt und können kugelförmige Wälzelemente **4**, wie in **Fig.** 1 dargestellt oder walzenförmige Wälzelemente sein. Die Wälzführungsvorrichtung der Erfindung ist verwendbar in Wälzführungsvorrichtungen mit verschiedensten Arten von Schienen **2** oder verschiedensten Arten von Wälzelementen **4**.

[0026] Der Lastabwälzoberflächenabschnitt **37** der Blockeinheit **34** weist mindestens die Lastabwälzoberfläche **32** auf. Die Lastabwälzoberfläche ist nicht auf eine spezifische Form begrenzt und kann eine Vielzahl von Formen annehmen. Der Lastabwälzoberflächenabschnitt **37** ist aus technischer Keramik hergestellt. Folglich wird ein Lastabwälzoberflächenabschnitt **37** umfassend der Lastabwälzoberfläche **31** mit einer herausragenden Abwälzzeitfestigkeit und Abriebsbeständigkeit bereitgestellt.

[0027] Bei der technischen Keramik, die den Lastabwälzoberflächenabschnitt **37** bildet, handelt es sich um eine technische Keramik mit einer volumenspezifischen Gewichtskraft von 2,5 bis 6,5 g/cm^3, einer Vierpunkt-Zeitfestigkeit von 300 bis 1500 MPa bei Raumtemperatur vorgeschrieben durch JIS-R-1601; einer Vickers Härte von 1000 bis 3000 Hv; und einem thermischen Ausdehnungskoeffizienten von 3,0 bis 11,0 × 10^{-6} / °C bei einer Temperatur von 40 bis 800°C. Hierbei versteht man unter "11,0 × 10^{-6}" entsprechend "11,0 mal 10^{-6}". Die technische Keramik mit derartigen Eigenschaften weist ein niedriges Gewicht auf und ist im Sinne der Festigkeit, Abriebsbeständigkeit und der Dimensionsstabilität hochwertig. Folglich wird eine derartige technische Keramik vorzugsweise für den Lastabwälzoberflächenabschnitt **37** der Blockhaupteinheit **34** verwendet.

[0028] In dem Fall, in dem die technische Keramik eine volumenspezifische Gewichtskraft von weniger als 2,5 g/cm^3 aufweist, kann der Wert für die Zeitfestigkeit des Lastabwälzoberflächenabschnitts aus dem vorstehenden Bereich herausfallen. In dem Fall, in dem die technische Keramik eine volumenspezifische Gewichtskraft von mehr als 6,5 g/cm^3 aufweist, wird der Lastabwälzoberflächenabschnitt **37** schwer. Ein bevorzugter volumenspezifischer Gewichtskraftbereich liegt zwischen 3,0 und 6,0 g/cm^3. Si_3N_4, welches später näher beschrieben werden wird, weist einen mehr bevorzugten volumenspezifischen Gewichtskraftbereich von 3,0 bis 3,4 g/cm^3 auf. Da eine derartige technische Keramik im Gewicht leichter als Metall ist, welches bisher für die Blockhaupteinheit verwendet wurde, ist der Lastabwälzoberflächenabschnitt **37** leichter. Insbesondere weist Keramiknitrit eine volumenspezifische Gewichtskraft von ungefähr 3,2 g/cm^3 auf und trägt daher zu einer Reduzierung des Gewichts des gesamten Blocks bei. Folglich wird die Massenkraft des Blocks verringert und dadurch Hochgeschwindigkeitsstart- und Stoppvorgänge des Blocks ermöglicht.

[0029] In dem Fall, in dem die technische Keramik eine Biegefestigkeit von weniger als 300 MPa aufweist, kann die erforderliche Festigkeit für den Lastabwälzoberflächenabschnitt **37** nicht erreicht werden. Der Grund, warum die Biegefestigkeit der technischen Keramik auf einen Wert von 1500 MPa oder weniger festgelegt ist, ist der, dass unter den momentanen Umständen Schwierigkeiten in der Herstellung einer technischen Keramik mit einer Biegesteifigkeit von mehr als 1500 MPa und den vorstehenden Eigenschaften auftreten. Eine bevorzugte Biegefestigkeit liegt zwischen 700 bis 1200 MPa bei Raumtemperatur, festgestellt durch eine Vierpunkt-Biegetest vorgeschrieben in JIS-R-1601. Si_3N_4, welches einer isostatischen Hochtemperaturkompression (HIP) unterzogen wurde, wird insbesondere bevorzugt als technische Keramik verwendet, die in den vorstehenden Bereich fällt.

[0030] In dem Fall, in dem die technische Keramik eine Vickers Härte von weniger als 1000 Hv aufweist, kann eine ausreichende erforderliche Festigkeit für den Lastabwälzoberflächenabschnitt **37** manchmal nicht erreicht werden. Der Grund, warum die Vickers Härte auf einen Wert von 3000 Hv oder weniger festgelegt ist, ist der, dass unter den momentanen Umständen Schwierigkeiten in der Herstellung einer technischen Keramik mit einer Vickers Härte von mehr als 3000 Hv und den vorstehenden Eigenschaften auftreten. Eine bevorzugte Vickers Härte entspricht 1300 bis 2000 Hv, und eine mehr bevorzugte Vickers Härte beträgt 1400 bis 1700 Hv.

[0031] In dem Fall, in dem der thermische Expansionskoeffizient der technischen Keramik bei 40 bis 800° C 11,0 × 10^{-6} /°C überschreitet, kann es scheitern, dass der Lastabwälzoberflächenabschnitt **37** eine ausreichende Dimensionsstabilität erreicht. Der Grund, warum der thermische Expansionskoeffizient auf 3,0 × 10^{-6} /°C oder mehr festgelegt ist, ist der, dass unter den momentanen Umständen Schwierigkeiten in der Herstellung einer technischen Keramik mit einem thermischen Expansionskoeffizienten von weniger als 3,0 × 10^{-6} /°C und den vorstehenden Eigenschaften auftreten. Ein bevorzugter thermischer Expansionskoeffizient ist 3,0 bis 4,0 × 10^{-6} /°C.

[0032] Die technische Keramik ist nicht auf eine spezifische Keramik begrenzt, solange die Keramik innerhalb des bevorzugten Eigenschaftsbereichs liegt. Folglich kann eine Vielfalt von technischen Keramiken verwendet werden. Insbesondere ist eine gesinterter Körper bestehend aus Siliziumnitrit (Si_3N_4) als technische Keramik bevorzugt. Siliziumnitrit (Si_3N_4), welches einer isostatischen Hochtemperaturkompression (HIP) unterzogen wurde, ist insbesondere bevorzugt.

[0033] Ein gesinterter Verbundkörper, welcher aus technischer Keramik wie Siliziumnitrit hergestellt ist, in dem ein anderer Typ keramischer Partikel dispergiert ist, kann ebenfalls verwendet werden. Dispergierte Partikel des gesinterten Verbundkörpers umfassen Keramikmaterialien wie Titannitrid (TiN), Siliziumkarbid (SiC), teilweise stabilisiertes Zirkondioxyd (ZrO_2), Aluminiumzirkondioxyd (Al_2O_3-ZrO_3), Aluminiumoxyd (Al_2O_3), einen SIALON Komplex (SiAlON), oder Mullit ($3Al_3O_3$-SiO_2). Auch in diesem Fall ist ein gesinterter Verbundkörper, der einer isostatischen Hochtemperaturkompression unterzogen wurde, insbesondere bevorzugt.

[0034] Ferner weist die technische Keramik eine herausragende Abwälzzeitfestigkeit, Druckfestigkeit und Gleiteigenschaft auf. Folglich sind die Abwälzzeitfestigkeit, Abriebsbeständigkeit und Gleiteigenschaft der Lastabwälzoberfläche **31** des Lastabwälzoberflächenabschnitts **37** verbessert. Infolgedessen kann der Abrieb und das Festfressen des Blocks **3** unfassend einen solchen Lastabwälzoberflächenabschnitt **37** verhindert werden, was in anderer Weise verursacht würde, wenn der Block **3** startet und stoppt. Ferner kann der Block **3** über einen langen Zeitraum ohne ein Vorkommen von Oberflächenblähung verwendet werden. Eine derartige technische Keramik weist eine niedrigere thermischen Expansion auf, als das Material, aus dem ein gewöhnlicher Block **3** gebildet ist. Folglich kann die Präzision der Lastabwälzoberfläche unabhängig von Änderungen in der Umgebungstemperatur gesichert werden. Infolgedessen kann ein Hochgeschwindigkeits-, Hochpräzisionsbetrieb des Blocks **3** realisiert werden.

[0035] Der Lastabwälzoberflächenabschnitt **37** kann als ein Laufring mit einem halbkreisförmigen Querschnittsprofil, wie z.B. dem in **Fig.** 5 dargestellten, integriert sein. Der Laufring **37'**, der als der vorangehende Lastabwälzoberflächenabschnitt **37** dient, ist in eine Laufgehäusenut **39** eingepasst, die in dem Hauptkörperabschnitt **38** der Blockhaupteinheit **37** ausgebildet und in der Blockhaupteinheit **34** aufgenommen ist. Der Lastabwälzoberflächenabschnitt **37**, der aus technischer Keramik hergestellt ist, ist durch ein gewöhnliches Herstellungsverfahren für ein keramisches Element, wie später beschrieben wird, hergestellt.

[0036] Wie in **Fig.** 5 dargestellt, ist der so gebildete Laufring **37'** in die Laufgehäusenut **39** eingepasst, die in der Blockhaupteinheit **34** ausgebildet ist. In dem Fall, in dem kugelförmige Wälzelemente verwendet werden, sind die Laufgehäusenut **39** und der Laufring **37'** vorzugsweise mit halbkreisförmigen Querschnittsprofilen versehen, die einander entsprechen. Auch in dem Fall, in dem walzenförmige Wälzelemente verwendet werden, sind die Laufgehäusenut **39** und der Laufring **37'** vorzugsweise mit Querschnittsprofilen versehen, die einander entsprechen. Mittels eines derartigen Profils kann der Laufring **37'** leicht in die Laufgehäusenut **39** eingepasst und eingearbeitet werden. Da der Laufring **37'** aus technischer Keramik hergestellt ist, die eine herausragenden Abwälzzeitfestigkeit aufweist, wird eine langlebige Wälzführungsvorrichtung realisiert.

[0037] Der Laufring **37'** und die Laufgehäusenut **39** sind vorzugsweise mit Querschnittsprofilen versehen, die einander entsprechen und derart ausgebildet, das sie zueinander drehbar sind. Als ein Ergebnis ist ein Selbstausrichtungsvorgang realisiert. Ein Rotationsmittelpunkt P1 des Laufrings **37'** ist mit Bezug auf die Breitenrichtung des Blocks **3** gegenüber einer inneren Position relativ zu einem Mittelpunkt P2 des Wälzkörpers (Kugel) **4**, wie in **Fig.** 3 dargestellt, versetzt.

[0038] Der Hauptkörperabschnitt **38** bildet den gesamten Aufbau der Blockhaupteinheit **34**. Der Hauptkörperabschnitt **38** ist nicht auf eine spezifische Form begrenzt, sondern kann eine Vielfalt von Formen annehmen. Der Hauptkörperabschnitt **38** ist aus bearbeitbarer Keramik hergestellt. Folglich kann ein Hauptkörperabschnitt **38** realisiert sein, der herausragenden mechanische Eigenschaften und eine leichte Bearbeitbarkeit aufweist. In diesem Zusammenhang ist der Ausdruck "bearbeitbare Keramik" eine allgemeine Bezeichnung von Keramik, die im Sinne der leichten spanenden Bearbeitung herausragend ist.

[0039] Als bearbeitbare Keramik, die den Hauptkörperabschnitt **38** bildet, kann eine bearbeitbare Keramik mit einer volumenspezifischen Gewichtskraft von 2,5 bis 6,5 g/cm^3, einer Vierpunkt-Biegefestigkeit von 100 bis 700 MPa bei Raumtemperatur vorgeschrieben durch JIS-R-1601; einer Vickers Härte von 300 bis 800 Hv, und einer Druckfestigkeit von 500 bis 1500 MPa verwendet werden. Die bearbeitbare Keramik mit derartigen Eigenschaften weist eine herausragenden Einfachheit der maschinellen Bearbeitung und eine mechanische Eigenschaft von großer Zeitfestigkeit auf und kann bevorzugter Weise für den Hauptkörperabschnitt **38** der Blockhaupteinheit **34** verwendet werden, welcher Gewindeschneiden oder Bearbeiten von Durchgangslöchern unterzogen wird.

[0040] In dem Fall, in dem die bearbeitbare Keramik eine volumenspezifische Gewichtskraft von weniger als 2,5 g/cm^3 aufweist, fällt der Wert der Zeitfestigkeit des Hauptkörperabschnitts aus dem vorstehenden Bereich. In dem Fall, in dem die bearbeitbare Keramik eine volumenspezifische Gewichtskraft von mehr als 6,5 g/cm^3 wird der Hauptkörperabschnitt **38** schwer. Ein bevorzugter spezifischer Gewichtskraftbereich liegt zwischen 2,5 und 3,5 g/cm^3 und ein mehr bevorzugter spezifischer Gewichtskraftbereich liegt zwischen 2,8 und 3,0 g/cm^3, was der spezifischen Gewichtskraft von AlN-BN Verbundkeramik entspricht, die später beschrieben werden wird. Da eine derartige bearbeitbare Keramik in ihrem Gewicht leichter als Metall ist, das bisher für den Hauptkörperabschnitt **38** verwendet wurde, kann der Hauptkörperabschnitt **38** in seinem Gewicht leichter gestaltet werden. Insbesondere weist AlBN Verbundkeramik eine volumenspezifische Gewichtskraft von ungefähr 2,9 g/cm^3 oder so ungefähr auf und kann folglich zu einer Reduzierung des Gewichts des gesamten Blocks beitragen. Folglich kann die Massenkraft des Blocks geringer gehalten werden und ein Hochgeschwindigkeits-Start- und Stoppvorgang des Blocks ist durchführbar.

[0041] In dem Fall, in dem die bearbeitbare Keramik eine Biegefestigkeit von weniger als 100 MPa aufweist, kann eine ausreichende Festigkeit, die für den Hauptkörperabschnitt **38** erforderlich ist, nicht erreicht werden. In dem Fall, in dem die Biegefestigkeit 700 MPa übersteigt, wird die Einfachheit der Bearbeitung der Keramik mangelhaft. Eine bevorzugte Biegefestigkeit liegt zwischen 250 und 350 MPa, die bei Raumtemperatur festgestellt wird, wie in JIS-R-1601 vorgeschrieben (durch einen Vierpunkt-Biegetest). AlN-BN Verbundkeramik wird insbesondere als bearbeitbare Keramik verwendet, die innerhalb des vorangegangenen Bereichs liegt, bevorzugt.

[0042] In dem Fall, in dem die bearbeitbare Keramik eine Vickers Härte von weniger als 300 Hv aufweist, kann es scheitern, dass die Keramik die mechanische Eigenschaft, die für den Hauptkörperabschnitt **38** bevorzugt ist, aufweist. In dem Fall, in dem die Vickers Härte 800 Hv überschreitet, kann die Einfachheit des mechanischen Bearbeitens vermindert sein. AlN-BN Verbundkeramik mit einer Vickers Härte von 350 bis 450 Hv oder in dieser Umgebung wird insbesondere als die bearbeitbare Keramik bevorzugt verwendet, die in den vorstehenden Bereich fällt.

[0043] In dem Fall, in dem die bearbeitbare Keramik eine Druckfestigkeit von weniger als 500 MPa oder mehr als 1500 MPA aufweist, kann die Einfachheit der Bearbeitung der Keramik vermindert sein. Die bevorzugte Druckfestigkeit reicht von 1000 bis 1200 MPa.

[0044] Die bearbeitbare Keramik ist nicht auf eine spezifische Keramik begrenzt, solange die Keramik innerhalb die bevorzugten Eigenschaftsbereiche fällt. Folglich kann eine Vielfalt von Arten von bearbeitbarer Keramik verwendet werden. Insbesondere ist eine AlBN-BN Verbundkeramik bevorzugt.

[0045] Derartige bearbeitbare Keramiken sind in ihrem Gewicht leichter als Metall, das bisher für die Blockhaupteinheit verwendet wurde. Folglich kann eine Reduzierung des Gewichts der Blockhaupteinheit **34** erreicht werden. Insbesondere weist die AlN-BN Verbundkeramik eine volumenspezifische Gewichtskraft von ungefähr 2,9 auf und kann folglich großartig zu einer Reduzierung des Gewichts des gesamten Blocks beitragen. Infolgedessen kann die Massenkraft des Blocks **3** reduziert werden, wodurch Hochgeschwindigkeits-Start- und Stoppvorgänge ermöglicht werden.

[0046] Die bearbeitbare Keramik hat herausragenden mechanische Eigenschaften, so wie Biegesteifigkeit und Druckfestigkeit. Folglich kann die bearbeitbare Keramik bevorzugter Weise als Hauptkörperabschnitt **38** der Blockhaupteinheit **34** in der Wälzführungsvorrichtung **1** verwendet werden. Da eine derartige bearbeitbare Keramik eine geringere thermische Expansion als das Material aufweist, welches einen gewöhnlich Block **3** bildet, kann trotz Änderungen der Umgebungstemperatur, die Präzision der bearbeitbaren Keramik gesichert werden. Folglich kann eine Hochgeschwindigkeits-, Hochpräzisionsbetrieb des Blocks **3** realisiert werden. Die Laufgehäusenut **39** ist in dem Hauptkörperabschnitt **38** ausgebildet. Die Laufgehäusenut **39** kann gebildet werden, wenn der Hauptkörperabschnitt **38** in einer vorbestimmten Form durch Sintern bearbeitbarer Keramik gebildet wird. Die Laufgehäusenut **39** kann auch geformt werden, nachdem der Hauptkörperabschnitt ohne die Laufgehäusenut **39** durch mechanische Bearbeitung geformt wurde. Der Hauptkörperabschnitt **38**, der aus bearbeitbarer Keramik hergestellt ist, wird durch ein gewöhnliches Herstellungsverfahren von keramischen Elementen gebildet, welches später beschrieben werden wird.

[0047] Die Laufgehäusenut **39** wird in einer vorbestimmten Form entsprechend der Form des Laufrings **37'** gebildet. Wie zuvor erwähnt, wird der Laufring **37'** in die Laufgehäusenut **39** eingepasst. Folglich werden die Dimension der Laufgehäusenut **39** und die des Laufrings **37'** unter Berücksichtigung eines Passungsmodus bestimmt.

[0048] Der Lastabwälzoberflächenabschnitt **37** mit der Lastabwälzoberfläche **31** ist aus technischer Keramik hergestellt, die eine herausragenden Abwälzzeitfestigkeit und Abriebswiderstandsfähigkeit aufweist, und der Hauptkörperabschnitt **38** ist aus bearbeitbarer Keramik hergestellt, die eine herausragende mechanische Eigenschaft und eine herausragende Einfachheit der Bearbeitung aufweist. Folglich kann die Blockhaupteinheit **34** eine Gewichtsreduzierung und hohe Festigkeit erreichen, wodurch Hochgeschwindigkeits-Start- und Stoppvorgänge mit geringer Massenkraft realisiert sind.

[0049] Ein Verfahren zur Herstellung der Blockhaupteinheit **34** mit dem Lastabwälzoberflächenabschnitt **37** bestehend aus technischer Keramik und dem Hauptkörperabschnitt **38** bestehend aus bearbeitbarer Keramik wird nun beschrieben. Der Lastabwälzoberflächenabschnitt **37** und der Hauptkörperabschnitt **38** können gemäß einem gewöhnlichen Verfahren geformt werden.

[0050] Keramik zum Zwecke des Formens, die aus entsprechenden Ausgangsmaterialien besteht, wird durch Granulation zuerst vorbereitet. Die Keramik wird durch Metallformgießen, Gummipressen oder Spritzgießen gegossen. Das Gussteil wird mechanischer Bearbeitung unterzogen und das dadurch bearbeitete Gussteil wird mittels Drucksintern, Heißpressen oder isostatischem Heißpressen gesintert. Im Anschluss wird das Gussteil mittels eines spanabhebenden Verfahrens einer Nachbearbeitung unterzogen, wodurch der Lastabwälzoberflächenabschnitt **37** in einer vorbestimmten Form und der Hauptkörperabschnitt **38** in einer vorbestimmten Form hergestellt werden.

[0051] Die Wälzführungsvorrichtung **1** wird durch Verwendung des derart hergestellten Lastabwälzoberflächenabschnitts **37** und des Hauptkörperabschnitts **38** hergestellt. Die Schiene **2** und die Wälzelemente **4**, die

gemäß einem gewöhnlichen Verfahren hergestellt wurden, werden verwendet.
[0052] Die Erfindung wird unter Bezugnahme auf Beispiele genauer beschrieben.

[Beispiel 1]

[0053] Ein Block **3** des Beispiels **1** umfasst eine Blockhaupteinheit **34**, hergestellt aus Keramik und Seitenabdeckungen **36**, hergestellt aus Metal. Der Block **3** hat eine Form der nominellen Modellzahl RSR7W, hergestellt durch THK Co., Ltd..
[0054] Genauer gesagt weist der Block **3** eine äußere Dimension auf, die einer Höhe von 9mm, einer Breite von 25 mm und einer Länge von 31 mm entspricht. Wie zuvor erwähnt, wird der Block **3** durch den Laufring **37'** mit der Lastabwälzoberfläche **31** und dem Hauptkörperabschnitt **38** gebildet.
[0055] Der Laufring **37'** ist aus Siliziumnitrid (Si3N4: hergestellt durch NGK INSULATORS Ltd.) hergestellt, welches technische Keramik ist, welche Keramik einer isostatischen Hochtemperaturkompression unterzogen wurde und eine volumenspezifische Gewichtskraft von 3,2 g/cm^3 eine Biegesteifigkeit von 1200 MPa, welche bei Raumtemperatur durch einen Vierpunkt-Biegetest festgestellt wird, wie es durch JIS-R-1601 vorgeschrieben ist, eine Vickers Härte von 1500 Hv und einen thermischen Expansionskoeffizienten von $3,0 \times 10^{-6}$ /°C bei 40 bis 800° C aufweist.
[0056] Der Hauptkörperabschnitt **38** ist aus AlN-BN Verbundkeramik hergestellt (Keramiktyp H, hergestellt durch ISHIHARA SANGYO Co., Ltd.). Genauer gesagt weist die AlN-BN Verbundkeramik eine volumenspezifische Gewichtskraft von 2,9 g/cm^3; eine Biegesteifigkeit von 300 MPa, die bei Raumtemperatur durch einen Vierpunkt-Biegetest festgestellt wird, wie es durch JIS-R-1601 vorgeschrieben ist, eine Vickers Härte von 390 Hv, und eine Druckfestigkeit von 1200 MPa auf.
[0057] Die Laufgehäusenut **39** ist in dem Hauptkörperabschnitt **38** ausgebildet und der Laufring **37'** wird in die Laufgehäusenut **39** eingepasst und eingebaut. Die Laufgehäusenut **39** des Hauptkörperabschnitts **38** wird mittels Schleifen gebildet, wobei ein drehender Schleifstein verwendet wird, oder durch spanabhebende Bearbeitung unter Verwendung eines Bohrers oder einer Reibahle. Die Laufgehäusenut **39** und der Laufring **37'** sind mit halbkreisförmigen Profilen versehen, die einander entsprechen.
[0058] Die Seitenabdeckungen **36** und Kugeln **4**, hergestellt aus SUS440C weisen eine spezifische Gewichtskraft von 7,8 g/cm^3 auf und sind an der Blockhaupteinheit **34** angebracht.

[Vergleichsbeispiel 1]

[0059] Ein Block **3** des Vergleichsbeispiels **1** umfasst eine Metallblockhaupteinheit **34** und Metallseitenabdeckungen **36**. Wie indem Fall von Beispiel **1** hat der derart hergestellt Block **3** eine Form der nominellen Modellzahl RSR7W, hergestellt durch THK Co., Ltd.. Genauer gesagt, hat der Block **3** äußere Dimensionen, die einer Höhe von 9 mm, einer Breite von 25 mm und einer Länge von 31 mm entsprechen. Die Blockhaupteinheit **34** ist nicht mit einem Laufring oder einer Laufgehäusenut versehen, so wie die in Verbindung mit Beispiel **1** beschriebenen.
[0060] Die Blockhaupteinheit **34**, Seitenabdeckungen **36** und Kugel sind alle aus SUS440C hergestellt, das eine spezifische Gewichtskraft von 7,8 g/cm^3 aufweist.

(Gewichtsbewertung)

[0061] Das Gewicht der Blockhaupteinheit **34** des Beispiels 1 und des Vergleichsbeispiels 1 wurden bewertet. Die Ergebnisse der Bewertung sind in Tabelle 1 dargestellt.

Tabelle 1

	Block			
	Blockhaupteinheit (g)	Seitenabdeckung (g)	Kugel (g)	Gesamtgewicht (g)
Beispiel 1	7,1	3,6	1,0	11,7
Vergleichs-Beispiel 1	17,2	3,6	1,0	21,8

[0062] Der Block **3** des Beispiels 1 weist ungefähr das halbe Gewicht des Blocks des Vergleichsbeispiels 1 auf, so dass eine bemerkbare Gewichtsreduzierung erreicht wurde. Als der Block **3** des Beispiels 1 tatsächlich auf einer Schiene bewegt wurde, konnten Hochgeschwindigkeits-Start- und Stoppvorgänge mit bemerkenswert kleiner Massenkraft erreicht werden.

(Bewertung der Lebensdauer)

[0063] Die technische Keramik, die in Beispiel 1 verwendet wurde und das SUS440C, das in dem Vergleichsbeispiel 1 verwendet wurde, wurden einer Lebensdauerbewertung unterzogen. Die Lebensdauerbewertung wurde auf der Basis von Ergebnissen eines Wälztests durchgeführt, welcher durch einen Reziprokschubwälzlebensdauerprüfer, wie er in **Fig.** 6A dargestellt ist, ausgeführt wurde. Ein Prüfstück, hergestellt in der Form eines Donuts (mit einem äußeren Durchmesser von 60 mm, einem inneren Durchmesser von 25 mm und einer Dicke von 10 mm), wie er in **Fig.** 6B dargestellt ist, wurde an dem Reziprokschubwälzlebensdauerprüfer angebracht und eine Hauptschaft rotiert.
[0064] Die technische Keramik verwendet in Beispiel 1, ist Si3N4 welches einem HIP unterzogen wurde. Das SU5440C, verwendet in dem Vergleichsbeispiel 1 ist ein gesintertes Stahlprodukt, welches gehärtet und angelassen wurde und eine Oberflächenhärte von 750 Hv oder in dieser Umgebung aufweist.
[0065] Tests wurden durchgeführt unter den folgenden Bedingungen: einer Last von 627 N pro Kugel; sechs Kugeln; einer Rotationsgeschwindigkeit von 800 min^{-1} (rpm); Schmieröl entsprechend LM Öl L68, hergestellt durch THK Co., Ltd.; und einer Ölmenge von 80 cm^3/min.
[0066] Der Wert L50 (Lebensdauerumdrehungen bei akkumulierter Fehlerwahrscheinlichkeit von 50%) der technischen Keramik,. die in Beispiel 1 verwendet wurde, betrug ungefähr 0,96 bis 1,59 × 10^7, wohingegen der Wert L50 des gesinterten Stahlprodukts aus SUS440C, welches in dem Vergleichsbeispiel 1 verwendet wurde, ungefähr 2,1 × 16^6 betrug.
[0067] Wie beschreiben wurde, ist gemäß einer Wälzführungsvorrichtung der Erfindung eine Gleitkörperhaupteinheit durch einen Lastabwälzoberflächenabschnitt, der aus technischer Keramik hergestellt ist und einem Hauptkörperabschnitt, der aus bearbeitbarer Keramik hergestellt ist, gebildet. Folglich können die vorstehenden Eigenschaften, die bisher erforderlich waren, erfüllt werden und eine Gewichtsreduzierung und hohe Festigkeit erreicht werden. Folglich sind Hochgeschwindigkeits-Start- und Stoppvorgänge mit geringer Massenkraft durchführbar.
[0068] Gemäß der Wälzführungsvorrichtung der Erfindung kann eine Laufgehäusenut leicht in den Hauptkörperabschnitt geformt werden, der aus bearbeitbarer Keramik mit einer leichten Bearbeitbarkeit hergestellt ist. Folglich kann ein Laufring, der ein Lastabwälzoberflächenbereich mit einer herausragenden Abwälzzeitfestigkeit ist, leicht in die Laufgehäusenut eingepasst werden. Der Laufring ist aus technischer Keramik hergestellt, die eine herausragenden Abwälzzeitfestigkeit aufweist. Infolgedessen kann eine lange Lebensdauer der Wälzführungsvorrichtung realisiert werden.

Patentansprüche

1. Wälzführungsvorrichtung, umfassend:
einen Laufschaft mit einer Wälzelementabwälzoberfläche, die in einer Längsrichtung davon ausgebildet ist;
ein Gleittisch mit einem endlosen Zirkulationskanal umfassend einer Lastabwälzoberfläche entsprechend der Wälzelementabwälzoberfläche, welcher Gleittisch relativ zu dem Laufschaft beweglich ist; und
mehrere Wälzelemente, die in dem endlosen Zirkulationskanal aufgenommen sind, so dass sie entsprechend der Relativbewegung des Laufschafts und des Gleittischs zirkulieren,
wobei der Gleittisch umfasst: eine Gleittischhaupteinheit mit der Lastabwälzoberfläche und einem zu der Lastabwälzoberfläche im wesentlichen parallelen Wälzelementrückführkanal; und Seitenabdeckungen, die jeweils einen Richtungswechselkanal zum Verbinden der Lastabwälzoberfläche und des Wälzelementrückführkanals aufweisen, welche Seitenabdeckungen an den entsprechenden Enden der Gleittischhaupteinheit angebracht sind, und
wobei die Gleittischhaupteinheit, umfasst: einen Lastabwälzoberflächenabschnitt, der aus technischer Keramik hergestellt ist und die Lastabwälzoberfläche aufweist; und einen Hauptkörperabschnitt, der aus bearbeitbarer Keramik hergestellt ist.

2. Wälzführungsvorrichtung nach Anspruch 1, ferner umfassend:
eine Laufgehäusenut, die in dem Hauptkörperabschnitt ausgebildet ist; und
einen Laufring, der als Lastabwälzoberflächenabschnitt dient, welcher Laufring in die Laufgehäusenut eingepasst ist.

3. Wälzführungsvorrichtung nach Anspruch 2, wobei die Laufgehäusenut und der Laufring halbkreisförmige Querschnittsprofile aufweisen, die einander entsprechen, welcher Laufring in Bezug auf die Laufgehäuse-

nut drehbar ist.

Beschreibung

1. Technisches Gebiet der Erfindung

[0001] Die vorliegende Erfindung bezieht sich auf einen Wälzelement-Störungsverhinderer für eine Führungsvorrichtung, wie einer Linearführungsvorrichtung, die einen kontinuierlichen Zirkulationspfad für Wälzelemente besitzt, ein Gelenklager, eine Kugelumlaufspindel oder eine Leiste. Der Wälzelement-Störungsverhinderer verhindert, dass Wälzelemente, die in gleichmäßigen Abständen innerhalb des kontinuierlichen Zirkulationspfades, der zwischen einem Paar von Lagerlaufflächen gebildet ist, wälzen, einander stören.

2. Beschreibung des Standes der Technik

[0002] In verschiedenen Wälzführungsvorrichtungen, die ein Lager besitzen, wird eine lineare Bewegung oder Rotation eines Paares von Lagerlaufflächen ermöglicht durch die Verwendung der Wälzbewegung von Wälzelementen, die aus Kugeln oder Walzen bestehen, die zwischen den Lagerlaufflächen getragen sind. Um den Reibwiderstand durch Vermeiden eines Kontakts zwischen den jeweiligen Wälzelementen zu verringern und eine geschmeidige Bewegung durch Anordnen jedes Wälzelementes in einer vorbestimmten Position zu erzeugen, ist es allgemeine Praxis, dass eine Anzahl von Wälzelementen zwischen den Lagerlaufflächen unter Verwendung eines Metallhalters eingebaut wird.

[0003] In der herkömmlichen Führungsvorrichtung, die den Metallhalter verwendet, da ein (Lager-)Käfig eine Anzahl von Taschen besitzt, und Wälzelemente drehbar in diese Taschen eingebaut werden, gibt es einen Vorteil, dass der Vorgang des Einbauens einer Anzahl von Wälzelementen in die Führungsvorrichtung erleichtert wird. Allerdings ist es erforderlich, eine Anzahl von Wälzelementen, die in die Taschen des Käfigs eingebaut sind, zu halten, damit diese nicht herausfallen, was zu einem Problem darin führt, dass es sehr viel Zeit beansprucht, den Käfig selbst herzustellen.

[0004] Um dieses Problem zu lösen, wurde daher ein Kugel-Störungsverhinderer (Wälzelement-Störungsverhinderer) zur Verwendung in einer Führungsvorrichtung vorgeschlagen, um eine gegenseitige Störung zwischen den jeweiligen Kugeln zu verhindern. Die Endlosführungsvorrichtung schließt ein eine Schiene, die einen Wälzpfad besitzt, eine Gleitplatte, die eine dem Wälzpfad gegenüberliegende Wälzrille besitzt und sich entlang der Schiene bewegt, und eine Anzahl von Kugeln (Wälzelementen). Bei einer aufgebrachten Belastung wälzen die Kugeln in einem kontinuierlichen Zirkulationspfad, der zwischen dem Wälzpfad der Schiene und der Wälzrille der Gleitplatte gebildet ist. Der Kugel-Störungsverhinderer ist aus einem flexiblen Harzverbinder zusammengesetzt, der einen eingelegten Abschnitt, der zwischen jeder Kugel eingelegt ist, und einen verbindenden Abschnitt zum Verbinden der eingelegten Abschnitte besitzt und jede Kugel wälzbar in einem angeordneten Zustand hält. Hierdurch wurden zahlreiche vorteilhafte Ergebnisse erzielt, einschließend 1) Erzielen geringen Geräusches und guter Klangqualität durch Beseitigen des metallischen Klangs infolge von Kollisionen zwischen den Kugeln (geringes Geräusch), 2) Vermindern des Verschleißes der Kugeln und Erhöhen des Zurückhaltens von Schmiermittel (Wartungsfreiheit für lange Zeit), 3) Erzielen ausgezeichnet hoher Geschwindigkeit durch Vermindern der relativen Reibungsgeschwindigkeit (hohe Geschwindigkeit), und 4) Glätten der Bewegung durch erhebliches Verringern der Wälzfluktuation (Gleiteigenschaft) (JP-B-6-56181, JP-A-5-52217, JP-A-5-126149, JP-A-5-196036, JP-A-5-196037, und JP-A-9-14264).

[0005] Auf diese Weise wird der derart aufgebaute Kugel-Störungsverhinderer, der aus dem Harzverbinder aufgebaut ist, in Schmierfett, Schmieröl oder Kühlmittel eingetaucht oder diesem unterworfen, in der Umgebung, in welcher der Verhinderer in dem Zirkulationspfad für die Wälzführungsvorrichtung eingeschlossen ist. Ebenso ist der Kugel-Störungsverhinderer Wirkungen unterworfen, wie Biegung, Zug, Druck, Verdrehen oder Kontaktreibung mit der Kugel zu jeglicher Zeit. Wenn er in dem Zirkulationspfad mit hoher Geschwindigkeit hin und her bewegt wird, vollzieht der Störungsverhinderer schwerwiegend und wiederholt einen Vorgang des Biegens, Zuges und Drucks. Darüber hinaus, wenn der Kugel-Störungsverhinderer, der aus dem Harzverbinder aufgebaut ist, in Schmierfett, Schmieröl oder Kühlmittel eingetaucht oder diesem unterworfen ist, absorbiert er Wasser und Öl, um anzuschwellen, was ein Zirkulationsversagen in dem Zirkulationspfad und eine Ablation des Verhinderers verursacht und die Dauerhaftigkeit, Gleiteigenschaften und den Verschleißwiderstand verschlechtert.

[0006] Daher muss der Wälzelement-Störungsverhinderer, der aus dem Harzverbinder aufgebaut ist, einen ausgezeichneten chemischen Ölwiderstand, Wasserwiderstand und chemischen Widerstand gegenüber Schmierfett, Schmieröl und Kühlmittel besitzen, zusätzlich zu der mechanischen Dauerhaftigkeit, den Gleiteigenschaften und den Verschleißwiderstand. Im Hinblick auf die Lebensdauer der Führungsvorrichtung ist es erforderlich, derart Dauerhaftigkeit und Verschleißfest zu sein, um etwas 30 000 km oder mehr zu laufen, bei geringer Variation des Gleitwiderstands, und ebenso gegenüber Öl, Wasser und Chemikalien widerstandsfähig zu sein.

[0007] Darüber hinaus war der Wälzelement-Störungsverhinderer, der aus dem Harzverbinder aufgebaut ist, nicht allzu problematisch darin, dass eine unnatürliche Belastung nur auf einen Teil des Harzverbinders während der Verwendung aufgebracht wurde, da der minimale Krümmungsradius für den kontinuierlichen Zirkulationspfad, der in der Führungsvorrichtung gebildet ist, relativ groß war, die Kugel als Wälzelement eingesetzt wurde, und die Form des Harzverbinders wurde ausgedacht. In den letzten Jahren wurden jedoch geringere Abmessungen und eine höhere Geschwindigkeit für die Führungsvorrichtung gefordert, und Walzen wurden als Wälzelemente eingesetzt, was zu dem Problem führt, dass die Dauerhaftigkeit, der Verschleißwiderstand und die Gleiteigenschaften beeinträchtigt sein können.

ZUSAMMENFASSUNG DER ERFINDUNG

[0008] Die vorliegenden Erfinder führten Forschung durch, um verbesserte Dauerhaftigkeit und Verschleißwiderstand zu erzielen, ohne verschiedene Merkmale (geringes Geräusch, Wartungsfreiheit für lange Zeit, hohe Geschwindigkeit und Gleiteigenschaften) des Wälzelement-Störungsverhinderers zu beeinträchtigen, insbesondere wenn er schwerwiegenden und wiederholten Wirkungen von Biegung, Zug und Druck unterworfen ist, und stellten fest, dass der Wälzelement-Störungsverhinderer unter Verwendung eines Elastomers aus thermoplastischem Harz hergestellt sein sollte, der eine spezifische Balance (Beziehung) für eine Spannung bei 10% Verlängerung, eine Zugfestigkeit und einen Biege-Elastizitätsmodul besitzt, um das Ziel zu erreichen, wodurch die Erfindung vervollständigt wird.

[0009] Dementsprechend ist es eine Aufgabe der Erfindung, einen Wälzelement-Störungsverhinderer für eine Führungsvorrichtung bereitzustellen, der verhindert, dass eine Anzahl von Wälzelementen, die in gleichmäßigen Abständen in einem kontinuierlichen Zirkulationspfad der Führungsvorrichtung zirkulieren, einander stören. Der Wälzelement-Störungsverhinderer besitzt nicht nur ausgezeichnete niedriges Geräusch, Wartungsfreiheit für lange Zeit, hohe Geschwindigkeit und Gleiteigenschaften, sondern auch ausgezeichnete Dauerhaftigkeit und Verschleißwiderstand, und kann stabil über lange Zeit verwendet werden.

[0010] Die vorliegende Erfindung stellt einen Wälzelement-Störungsverhinderer für eine Führungsvorrichtung bereit, um zu verhindern, dass eine Anzahl von Wälzelementen, die in gleichmäßigen Abständen in einem kontinuierlichen Zirkulationspfad der Führungsvorrichtung wälzen, einander stören, worin der Wälzelement-Störungsverhinderer aus einem Elastomer aus thermoplastischen Harz gebildet ist, das physikalische Eigenschaften in Übereinstimmung mit einem Ausdruck $(A \times B) \div C \geq 18$ besitzt, wobei A eine Spannung bei 10% Verlängerung ist, B eine Zugfestigkeit ist und C ein Biege-Elastizitätsmodul ist.

[0011] Als Elastomer aus thermoplastischen Harz können beispielsweise Polyamidharz-Elastomer, Polyesterharz-Elastomer, Polyuretanharz-Elastomer, Styrolharz-Elastomer und Olefinharz-Elastomer verwendet werden. Diese sollten hoch widerstandsfähig gegenüber Öl, Wasser und Chemikalien in der Betriebsumgebung der Wälzführungsvorrichtung sein, insbesondere in der Betriebsumgebung, in welcher die Führungsvorrichtung in Schmierfett, Schmieröl oder Kühlmittel eingetaucht oder diesen unterworfen ist. Der Wasserabsorptionskoeffizient, gemessen in einer Umgebung eines Gleichgewichtsfeuchtigkeitsanteils bei 23°C von 65% RH, beträgt 1,5 Gewichts-% oder weniger, und bevorzugt 0,5 Gewichts-% oder weniger. Der Anschwellfaktor, gemessen in einem Eintauchversuch einer Chemikalie bei einer Temperatur von 85°C für 672 Stunden, beträgt 3% oder weniger. Darüber hinaus beträgt die Zugfestigkeitsaufrechtserhaltung in einem Eintauchversuch in kochendes Wasser bei 100°C 70% oder mehr nach 10 Tagen, und bevorzugt 80% oder mehr.

[0012] In der vorliegenden Erfindung werden Elastomere aus thermoplastischem Harz eingesetzt, die physikalische Eigenschaften besitzen, welche den Ausdruck $(A \times B) \div C \geq 18$ erfüllen (A: Spannung bei 10% Verlängerung, B: Zugfestigkeit, C: Biege-Elastizitätsmodul). Obwohl geringfügig unterschiedlich in Abhängigkeit von der Art der Wälzführungsvorrichtung und davon, ob das Wälzelement eine Kugel oder eine Walze ist, liegt die Spannung bei 10% Verlängerung A im Bereich von 60 bis 200 kgf/cm^2, und bevorzugt von 90 bis 160 kgf/cm^2, die Zugfestigkeit B liegt im Bereich von 340 bis 460 kgf/cm^2, und bevorzugt von 360 bis 430 kgf/cm^2, und der Biege-Elastizitätsmodul C liegt im Bereich von 1000 bis 5000 kgf/cm^2, und bevorzugt von 1200 bis 2700 kgf/cm^2.

[0013] Falls die Spannung bei 10% Verlängerung des Elastomers aus thermoplastischen Harz nicht weniger als 60 kgf/cm^2 ist, wird die Form des Wälzelements-Störungsverhinderers gegenüber einer Zentrifugalkraft, die auf das Wälzelement der Führungsvorrichtung in schnellem Betrieb wirkt, aufrechterhalten, was dazu führt, dass der Gleitwiderstand in dem kontinuierlichen Zirkulationspfad der Führungsvorrichtung abnimmt. Falls im Gegensatz hierzu diese nicht mehr als 200 kgf/cm^2 beträgt, wird ein Problem eines Biegeermüdungsversagens verhindert. Falls die Zugfestigkeit nicht weniger als 340 kgf/cm^2 beträgt, wird die Dauerhaftigkeit erhöht, oder falls sie umgekehrt nicht mehr als 460 kgf/cm^2 beträgt, kann das Problem des Biegeermüdungsversagens verhindert werden. Falls darüber hinaus der Biege-Elastizitätsmodul nicht weniger als 1000 kgf/cm^2 und nicht mehr als 5000 kgf/cm^2 beträgt, werden die Gleiteigenschaften erhöht.

[0014] Hierin ist es erforderlich, dass die Führungsvorrichtung zur Verwendung mit dem Wälzelement-Störungsverhinderer der Erfindung ein Paar von Lagerlaufflächen, und den kontinuierlichen Zirkulationspfad für die Wälzelemente, die mit einer zwischen dem Paar von Lagerlaufflächen aufgebrachten Belastung wälzen, besitzt, und die Führungsvorrichtung kann beispielsweise eine Endlosspur (englisch: endless track), ein Gelenklager, eine Kugelumlaufspindel oder eine Leiste sein.

[0015] Der Wälzelement-Störungsverhinderer der vorliegenden Erfindung kann verschiedene Formen annehmen, in Abhängigkeit von der Art der Führungsvorrichtung, in welcher er angewendet wird. Beispielsweise in einem Fall, in welchem die Führungsvorrichtung eine Linearführungsvorrichtung für eine Endlosspur ist, besitzend eine Spurschiene (eine Lagerlauffläche), die einen Wälzpfad besitzt, eine Gleitplatte (andere Lagerlauffläche), die eine dem Wälzpfad gegenüberliegende Wälzrille besitzt und sich entlang der Spurschiene bewegt, und eine Anzahl von Wälzelementen, die mit einer aufgebrachten Belastung zwischen dem Wälzpfad der Spurschiene und der Wälzrille der Leitplatte wälzen, ist es bevorzugt, dass der Wälzelement-Störungsverhinderer aus einem flexiblen Harzverbinder besteht, der einen eingelegten Abschnitt, der zwischen den jeweiligen Wälzelementen eingelegt ist, und einen verbindenden Abschnitt zum Verbinden jedes eingelegten Abschnitts, und bevorzugt eine Anzahl von Wälzelementen wälzbar durch die eingelegten Abschnitte und den verbindenden Abschnitts halten kann.

[0016] Darüber hinaus, in dem Fall, in welchem der Wälzelement-Störungsverhinderer aus diesem flexiblen Harzverbinder aufgebaut ist, kann der Harzverbinder mit einem abgeschrägten Führungsabschnitt an beiden Enden ausgestattet sein, um den oberen Endabschnitt des Harzverbinders zu führen, wodurch wenn die Führungsvorrichtung in dem kontinuierlichen Zirkulationspfad bewegt wird, insbesondere wenn der obere Abschnitt des Wälzelement-Störungsverhinderers in einen richtungsändernden Pfad des Zirkulationspfades eintritt, oder von dem richtungsändernden Pfad austritt, der obere Endabschnitt geführt wird, um die Führungsvorrichtung sanft zu bewegen. Durch Bilden des abgeschrägten Führungsabschnitts an beiden Enden des Harzverbinders kann der Wälzelement-Störungsverhinderer sanft in jeglicher Vorwärts- und Rückwärtsrichtung in der Hin- und Herbewegung der Führungsvorrichtung geführt werden.

[0017] Die Länge des zu gießenden Wälzelement-Störungsverhinderers wird unter Berücksichtigung der Länge des Zirkulationspfades der Führungsvorrichtung, die diesen verwendet, festgelegt. Falls allerdings die Führungsvorrichtung erhöhte Abmessungen besitzt und die Länge des Zirkulationspfades groß ist, kann der Wälzelement-Störungsverhinderer in zwei oder drei Teile zum Gießen aufgeteilt werden, wodurch die Abmessungen der Form verringert werden können. In diesem Fall ist jeder Harzverbinder, der jeweils aus zwei oder drei Teilen besteht, die aus dem Wälzelement-Störungsverhinderer herausgeteilt sind, mit einem abgeschrägten Führungsabschnitt an beiden Enden gebildet.

[0018] In dem Fall, in welchem der Wälzelement-Störungsverhinderer der Erfindung auf die lineare Führungsvorrichtung für eine Endlosspur angewendet wird, falls die Wälzelemente Kugeln sind, besitzt das Elastomer aus thermoplastischem Harz, das den Harzverbinder bildet, derartige Eigenschaften, dass die Spannung bei 10% Verlängerung A im Bereich von 60 bis 150 kgf/cm^2 liegt, und bevorzugt von 90 bis 130 kgf/cm^2, die Zugfestigkeit B im Bereich von 340 bis 400 kgf/cm^2 liegt, und bevorzugt von 350 bis 380 kgf/cm^2, und der Biege-Elastizitätsmodul C im Bereich von 1000 bis 2000 kgf/cm^2 liegt, und bevorzugt von 1200 bis 1800 kgf/cm^2. Durch Anwenden der Werte in den obigen Bereichen für die Spannung bei 10% Verlängerung A, die Zugfestigkeit B und den Biege-Elastizitätsmodul C kann der Kugel-Störungsverhinderer die ausgezeichneten und ausgeglichenen Leistungsmerkmale (geringes Geräusch, Wartungsfreiheit für lange Zeit, hohe Geschwindigkeit, Gleiteigenschaften, Dauerhaftigkeit und Verschleißwiderstand) aufweisen.

[0019] In dem Fall, in welchem der Wälzelement-Störungsverhinderer der vorliegenden Erfindung auf die lineare Führungsvorrichtung für eine Endlosspur angewendet wird, falls die Wälzelemente Walzen sind, besitzt das Elastomer aus thermoplastischem Harz, das den Harzverbinder bildet, derartige Eigenschaften, dass die Spannung bei 10% Verlängerung A im Bereich von 80 bis 200 kgf/cm^2 liegt, und bevorzugt von 100 bis 160 kgf/cm^2, die Zugfestigkeit B im Bereich von 380 bis 460 kgf/cm^2 liegt, und bevorzugt von 430 bis 460 kgf/cm^2, und der Biege-Elastizitätsmodul C im Bereich von 1500 bis 5000 kgf/cm^2 liegt, und bevorzugt von 2000 bis 4000 kgf/cm^2. Durch Anwenden der Werte in den obigen Bereichen für die Spannung bei 10% Verlängerung A, die Zugfestigkeit B und den Biege-Elastizitätsmodul C kann der Walzen-Störungsverhinderer die ausgezeichneten und ausgeglichenen Leistungsmerkmale (geringes Geräusch, Wartungsfreiheit für lange Zeit, hohe Geschwindigkeit, Gleiteigenschaften, Dauerhaftigkeit und Verschleißwiderstand) aufweisen.

[0020] Darüber hinaus, in dem Fall, in welchem die Führungsvorrichtung eine Kugelumlaufspindel ist, besitzend eine Spindelachse (eine Lagerlauffläche) mit einem spiralförmigen Wälzpfad für eine Kugel, eine Mutter (andere Lagerlauffläche) mit einer spiralförmigen Wälzrille, die dem spiralförmigen Wälzpfad gegenüberliegt, und eine Anzahl von Kugeln, die bei einer aufgebrachten Belastung zwischen dem spiralförmigen Wälzpfad der Spindelachse und der spiralförmigen Wälznut der Mutter wälzen, wobei der Kugel-Störungsverhinderer der Harzverbinder wie derjenige der linearen Führungsvorrichtung für Endlosspur oder ein zwischen den jeweiligen Kugeln eingelegter Abstandhalter sein kann.

[0021] Der Wälzelement-Störungsverhinderer der vorliegenden Erfindung kann durch herkömmliche, bekannte Verfahren hergestellt sein, unter Verwendung des Elastomers aus thermoplastischem Harz wie vorstehend beschrieben.

[0022] Beispielsweise in einem Fall, in welchem der Wälzelement-Störungsverhinderer durch den Harzverbinder gebildet ist kann eine Anzahl von Wälzelementen als ein Kern durch Spritzgießen oder ein sogenanntes Einspritzgießen (englisch: insert molding), (wie in JP-A-6-56181, JP-A-5-52217, JP-A-5-126149, JP-A-5-196036, JP-A-5-196037 und JP-A-9-14264 beschrieben), oder andere Verfahren hergestellt sein.

AUSFÜHRLICHE BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSFORMEN

[0041] Die bevorzugten Ausführungsformen der vorliegenden Erfindung werden nachfolgend unter Bezugnahme auf die begleitenden Zeichnungen beschrieben.

Erste Ausführungsform

[0042] **Fig.** 1 bis 6 zeigen einen Walzen-Störungsverhinderer RC gemäß einer ersten Ausführungsform der Erfindung und ein linear gleitendes Walzenlager, in das der Walzen-Störungsverhinderer RC eingebaut ist.

[0043] Dieser Walzen-Störungsverhinderer RC schließt einen flexiblen Harzverbinder **12** ein, der eingelegte Abschnitte **12**a besitzt, die zwischen jeder einer Anzahl von Walzen **11** eingelegt sind, welche aus Lagerstahl (SUJ2) hergestellt und unter gleichmäßigen Abständen angeordnet sind, und besitzt ein Paar von verbindenden Abschnitten **12**b, die jeden eingelegten Abschnitt **12**a verbinden und eine Anzahl von Walzen **11** im linearen Zustand und wälzbar trägt, wie insbesondere in **Fig.** 3 bis 6 gezeigt. An beiden Enden des Harzverbinders **12** ist ein abgeschrägter Führungsabschnitt **13** gebildet, der eine annähernd ähnliche Form einer Walze besitzt, um die Walze **11**a, die an dem Ende angeordnet ist, zu umgeben, wie in **Fig.** 6 gezeigt.

[0044] Das linear gleitende Walzlager, in das der Walzen-Störungsverhinderer RC eingebaut ist, schließt im wesentlichen eine metallische Schiene (eine Lagerlauffläche) **14**, die Steifigkeit besitzt, eine metallische Gleitplatte (andere Lagerlauffläche) **15**, die Steifigkeit besitzt, ein Walzführungselement **16**, das aus synthetischen Harz hergestellt ist und in ein Loch **15**b befestigt ist, das entlang der Längsrichtung in der Gleitplatte **15** gestanzt ist, befestigt ist, einen Deckel **17**, der aus synthetischem Harz hergestellt ist und an der Gleitplatte **15** zusammen mit dem Walzenführungselement **16** befestigt ist, und eine Anzahl von Walzen **11**, die kettenartig durch den Harzverbinder **12** wie in **Fig.** 1 und 2 gezeigt getragen sind, ein.

[0045] In dieser ersten Ausführungsform ist die Führungsschiene **14** mit einem glattflächigen Wälzpfad **14**a für die Walze **11** an jedem Schulterabschnitt gebildet, und die Gleitplatte **15** ist mit einem Lastwalzen-Wälzpfad **15**a für die Walze **11**, die eine Belastung aufbringt, gebildet. Darüber hinaus ist das Walzenführungselement **16** mit einer Nicht-Last-Walzenführungsbohrung **16**a zum Führen der Walze **11**, die in einem nicht belasteten Zustand walzt, gebildet, und der Deckel **17** ist mit einem Richtungsänderungspfad, nicht gezeigt, gebildet, der den kontinuierlichen Zirkulationspfad der Walze **11** durch Verbinden des Belastungswalzen-Wälzpfades **15**a der Gleitplatte **15** und der Nicht-Belastungswalzen-Führungsbohrung **16**a des Walzenführungselements **16** darstellt.

Zweite Ausführungsform

[0046] **Fig.** 7 zeigt einen Walzen-Störungsverhinderer RC gemäß einer zweiten Ausführungsform der Erfindung. Dieser Walzen-Störungsverhinderer RC schließt einen flexiblen Harzverbinder **22** ein, der plattenartige, eingelegte Abschnitte **22**a besitzt, die zwischen dem jeweiligen einer Anzahl von Walzen **21** eingelegt sind, welche aus Lagerstahl (SUJ2) hergestellt und unter gleichmäßigen Abständen angeordnet sind, und schließt ein Paar von verbindenden Abschnitten **22**b ein, die jeweils die eingelegten Abschnitte **22**a auf beiden Seiten der Walze **21** verbinden, und eine Anzahl von Walzen **21** in linearen Zustand und wälzbar anordnet. Auf beiden Enden des Harzverbinders **22** ist ein abgeschrägter Führungsabschnitt **23** gebildet, der eine halbzylindrische Form und etwa denselben Krümmungsradius wie die Walze **21**a besitzt.

[0047] Der Walzen-Störungsverhinderer RC gemäß der zweiten Ausführungsform trägt die Walzen **21** nicht durch Verwenden des Harzverbinders **22**, sondern ist in den kontinuierlichen Zirkulationspfad des linear gleitenden Walzenlagers auf dieselbe Weise wie die der Walzen-Störungsverhinderer RC der ersten Ausführungsform eingebaut, wodurch verhindert wird, dass die Walzen **21** einander berühren und einander stören.

Dritte Ausführungsform

[0048] **Fig.** 8 bis 11 zeigen einen Kugel-Störungsverhinderer BC gemäß einer dritten Ausführungsform der Erfindung. Dieser Kugel-Störungsverhinderer BC schließt ein einen flexiblen Harzverbinder **32**, der eingelegte Abschnitte **32**a besitzt, die zwischen den jeweiligen einer Anzahl von Kugeln **31** eingelegt sind, welche aus Lagerstahl (SUJ2) hergestellt und in gleichmäßigen Abständen angeordnet sind, und ein Paar von verbindenden Abschnitten **32**b zu verbinden der jeweiligen eingelegten Abschnitte **32**a und zum Tragen einer Anzahl von Kugeln **21** in linearem Zustand und wälzbar. Auf beiden Enden des Harzverbinders **32** ist ein abgeschrägter Führungsabschnitt **33** gebildet, der etwa dieselbe Form wie die Kugel **31**a besitzt, und die Kugel **31**a, die an dem Ende angeordnet ist, zu umgeben.

[0049] Dieser Kugel-Störungsverhinderer BC ist ebenso in dem kontinuierlichen Zirkulationspfad des linear gleitenden Kugellagers auf dieselbe Weise wie die der Walzen-Störungsverhinderer RC der ersten Ausführungsform eingebaut.

Vierte Ausführungsform

[0050] **Fig.** 12 bis 15 zeigen ein Kugel-Störungsverhinderer BC gemäß einer vierten Ausführungsform der Erfindung und eine Kugelumlaufspindel BS, in welche der Kugel-Störungsverhinderer BC eingebaut ist.

[0051] Dieser Kugel-Störungsverhinderer BC schließt eine Anzahl von Abstandhaltern **42** ein, die einen kugelförmigen, konkaven Abschnitt **42** zum Aufnehmen einer Kugel **41** teilweise auf der Frontfläche und der Rückfläche besitzen. Der Kugel-Störungsverhinderer BC ist in einen kontinuierlichen Zirkulationspfad der Kugelumlaufspindel eingebaut, die einschließt eine Spindelachse (eine Lagerlauffläche) **44**, die einen spiralförmigen Wälzpfad **44** für die Kugel **41** besitzt, eine Mutter (andere Lagerlauffläche) **45** mit einer spiralförmigen Wälzrille **45**a, die dem spiralförmigen Wälzpfad gegenüberliegt, und eine Anzahl von Kugeln **41**, die zwischen dem spiralförmigen Wälzpfad **44**a der Spindelachse **44** und der spiralförmigen Wälzrille **45**a der Mutter **45** bei aufgebrachter Belastung wälzen, und ist zwischen benachbarten Kugeln **41** angeordnet, um zu verhindern, dass die Kugeln **41** einander berühren und einander stören.

[0052] In dieser vierten Ausführungsform besitzt die Mutter **45** ein annähernd U-förmiges Rückführrohr **46**, das an einer Klemmfläche **45**b angebracht ist, die durch Abschneiden eines Teils des äußeren Umfangsabschnitts gebildet ist. Beide Endabschnitte des Rückführrohres **46** durchdringen eine Umfangswand der Mutter **44**, um sich in die spiralförmige Wälzrille **45**a, die dem spiralförmigen Wälzpfad **44**a der Spindelachse **44** gegenüberliegt, zu öffnen. Darüber hinaus sind an beiden Enden Kugelaufnahmeabschnitte **46**a gebildet, um die Kugeln **41**, die zwischen dem spiralförmigen Wälzpfad **44**a und der spiralförmigen Wälzrille **45**a bei aufgebrachter Belastung in das Rückführrohr **46** wälzen, aufzunehmen, und um die Kugeln **41**, die durch das Rückführrohr **46** wälzen, zwischen den spiralförmigen Wälzpfad **44**a und die spiralförmige Wälzrille **45**a zuzuführen. Der kontinuierliche Zirkulationspfad der Kugeln **41** wird durch die Spindelachse **44**, die Mutter **45** und das Rückführrohr **46** gebildet.

[0053] Der Abstandhalter **42**, der den Kugel-Störungsverhinderer BC der vierten Ausführungsform darstellt, ist zwischen benachbarten Kugeln **41**, die in den kontinuierlichen Zirkulationspfad der Kugelumlaufspindel eingebaut sind, angeordnet, zirkuliert in diesem Zirkulationspfad zusammen mit den Kugeln **41**, und verhindert, dass die Kugeln **41** einander berühren und einander stören.

Fünfte Ausführungsform

[0054] **Fig.** 16 bis 18 zeigen einen Kugel-Störungsverhinderer BC, der in eine Kugelumlaufspindel BS auf dieselbe Weise wie in der vierten Ausführungsform der Erfindung eingebaut ist.

[0055] Dieser Kugel-Störungsverhinderer BC schließt, anders als derjenige der vierten Ausführungsform, jedoch wie derjenige der dritten Ausführungsform, einen flexiblen Harzverbinder **52**, der eingelegte Abschnitte **52**a, die zwischen den jeweiligen einer Anzahl von Kugeln **51**, die in gleichmäßigen Abständen angeordnet sind, eingelegt ist, und einen verbindenden Abschnitt **52**b, der jeden eingelegten Abschnitt **52**a verbindet und eine Anzahl von Kugeln **41** wälzbar trägt, ein. Auf beiden Enden des Harzverbinders **52** ist jeweils ein abgeschrägter Führungsabschnitt **53** gebildet, um die Kugel **51**a, die an dem Ende angeordnet ist, zu umgeben.

[0056] In **Fig.** 16 bis 18 ist die Kugelwälzrille **54**a in der Spindelachse **54** gebildet, und die Nicht-Belastungswälzrille **55**a ist in der Mutter **55** gebildet. Darüber hinaus ist ein Ablenker **56**, der an der Mutter **54** befestigt ist und den kontinuierlichen Zirkulationspfad zwischen der Spindelachse **54** und der Mutter **55** bildet, mit einer Kugelrückführrille **56**a gebildet, wodurch eine Anzahl von Kugeln, die durch den Harzverbinder **52** verbunden sind, in dem durch die Kugelwälzrille **54**a der Spindelachse **54**, die Nicht-Belastungswälzrille **55**a der Mutter **55** und die Kugelrückführrille **56**a des Ablenkers **56** gebildeten Zirkulationspfades wälzen können, bei aufgebrachter Belastung.

[0057] Dieser Kugel-Störungsverhinderer BC der fünften Ausführungsform verhindert, dass die Kugeln **51** einander berühren und einander stören, wie der Kugel-Störungsverhinderer BC der vierten Ausführungsform.

Beispiele

[0058] Die vorliegende Erfindung wird nachfolgend genauer auf der Grundlage einiger experimenteller Beispiele (Beispiele und Vergleichsbeispiele) beschrieben.

Experimentelle Beispiele 1 bis 4

[0059] Unter Verwendung von Polyesterharzelastomer (Handelsname Perplene EN1000, EN2000, EN3000 und EN5000, hergestellt durch TOYOBO Co., Ltd.) wie in Tabelle 1 angegeben als Elastomer aus thermoplastischem Harz wurden 75 aus Lagerstahl (SUJ2) hergestellte Rollen mit einer Größe von 5 mm $\varnothing \times 7$ mm als ein Kern durch Spritzgießen hergestellt, von der Form gelöst, zusammen mit einer Anzahl von Walzen, wodurch der Walzen-Störungsverhinderer gegossen wurde, der eine Länge von etwa 340 mm und eine wie in **Fig.** 3 bis 6 für die erste Ausführungsform gezeigte Form besitzt.

[0060] Die erhaltenen Walzen-Störungsverhinderer der jeweiligen Vergleichsbeispiele 1 bis 4 wurden im Hinblick auf Dauerhaftigkeit, Gleiteigenschaften, Verschleißwiderstand, Wasserabsorptionsvermögen, Schwelleigenschaften und Wasserwiderstand untersucht.

[0061] Die Ergebnisse sind unten in Tabelle 1 aufgelistet.

Dauerhaftigkeit

[0062] Wie in **Fig.** 1 und 2 gezeigt, wurde der Walzen-Störungsverhinderer der jeweiligen experimentellen Beispiele 1 bis 4 in den kontinuierlichen Zirkulationspfad des linear gleitenden Walzenlagers eingebaut, mit dessen Schiene im befestigten Zustand, und die Gleitplatte wurde unter den Bedingungen mit einer Geschwindigkeit f von 2000 m/min hin und her bewegt, bei einem Hub St von 2500 mm, und einer Beschleunigung von 1 G. Die Dauerhaftigkeit wurde mit drei Stufen bewertet, in denen ○ keine Abnormalität nach Durchlaufen von 30 000 km anzeigt, Δ einige teilweise Beschädigung nach Durchlaufen von 30 000 km, jedoch keine Abnormalität beim Durchlaufen anzeigt, und X eine Abnormalität anzeigt, wie ein Brechen nach Durchlaufen von weniger als 30 000 km.

Gleiteigenschaften

[0063] Auf dieselbe Weise wie die Messung der Dauerhaftigkeit, wurde der Walzen-Störungsverhinderer der jeweiligen experimentellen Beispiele 1 bis 4 in den kontinuierlichen Zirkulationspfad des linear gleitenden Walzenlagers eingebaut, mit dessen Schiene im befestigten Zustand, und die Gleitplatte wurde durch eine Kraftmessdose geschoben, um den Wälzwiderstand der Gleitplatte in der Schiene bei einer Messfrequenz von 500 Hz für diese Kraftmessdose zu messen. Die Gleiteigenschaften wurden mit drei Stufen bewertet, in denen ○ bedeutet, dass sie für den Betrieb geeignet sind, da die Widerstandsvariation 25% oder weniger des Wälzwiderstandes beträgt, Δ ist für den Betrieb verwendbar obwohl die Widerstandsvariation teilweise weniger als 25% des Messwiderstandes beträgt, und X ist nicht verwendbar, da die Widerstandsvariation vollständig unterhalb 25% des Messwiderstandes liegt.

Verschleißwiderstand

[0064] Auf dieselbe Weise wie die Messung der Dauerhaftigkeit wurde der Walzen-Störungsverhinderer der jeweiligen experimentellen Beispiele 1 bis 4 in den kontinuierlichen Zirkulationspfad des linear gleitenden Walzenlagers eingebaut, mit dessen Schiene im befestigten Zustand, und die Gleitplatte wurde unter den Bedingungen mit einer Geschwindigkeit f von 200 m/min. einem Hub St von 2500 mm und einer Beschleunigung von 1 G hin und her bewegt, um den Verschleißbetrag an der Ecke am oberen Ende des Harzverbinders für den Walzen-Störungsverhinderer zu messen. Der Verschleißwiderstand wurde mit drei Stufen bewertet, in denen ○ keine Abnormalität des Verschleißes anzeigt, Δ zeigt etwas anfänglichen Verschleiß, jedoch keinen progressiven Verschleiß an, und X bedeutet progressiven (fortschreitenden) Verschleiß an dem oberen Ende während des Laufens, was zu einem Brechen führt.

Wasserabsorptionsvermögen

[0065] Unter Verwendung von vier Arten von Polyesterharzelastomer, das in jeden der experimentellen Beispiele 1 bis 4 wie in Tabelle 1 aufgelistet eingesetzt wurde, wurde ein Hantelprobekörper vom Typ JIS 3 in Übereinstimmung mit JIS K6251 hergestellt, und die Abmessungsvariation des Hantelprobekörpers wurde gemessen in einer Umgebung eines Gleichgewichtsfeuchtigkeitsgehalts bei 23°C von 65% RH, und das Wasserabsorptionsvermögen wurden mit drei Stufen bewertet, in denen O 0,5% oder weniger ist, Δ von 5% bis 1,5% ist, und X mehr als 1,5% ist.

Schwelleigenschaften

[0066] Auf dieselbe Weise wie in dem Test des Wasserabsorptionsvermögens wurde ein Hantelprobekörper vom Typ JIS 3 hergestellt, und der Hantelprobekörper wurde in das Versuchsöl bei einer Temperatur von 85°C für 672 Stunden eingetaucht, unter Anwendung eines synthetischen Kühlmittels (Synthylo hergestellt durch Castorol), eines löslichen Kühlmittels (Microcut 3850-LH hergestellt durch Japan Quakerchemical) und eines Emulsionskühlmittels (Yushiroken EC50T-3 hergestellt durch Yushiro Chemical Industries) als Versuchsöle, und unter Verwendung einer Umweltprüfmaschine (hergestellt von KATO: sse740RA). Der Schwellfaktor wurde anhand der Werte der Abmessungsvariation des Hantelprobekörpers infolge Schwellens berechnet und mit drei Stufen bewertet, in denen ○ 1,5% oder weniger ist, Δ von 1,5% bis 3% ist, und X mehr als 3% ist.

Wasserwiderstand

[0067] Auf dieselbe Weise wie der Test des Wasserabsorptionsvermögens und der Schwelleigenschaften wurde ein Hantelprobekörper vom Typ JIS3 hergestellt, und in kochendes Wasser bei 100°C für zehn Tage eingetaucht, um die Veränderung der Zugfestigkeit (Zugfestigkeit: 500 mm/min) des Hantelprobekörpers zu messen. Die Aufrechterhaltung der Zugfestigkeit wurde anhand der Veränderung der Zugfestigkeit berechnet und mit drei Stufen bewertet, in denen O eine Aufrechterhaltung der Zugfestigkeit von 80% oder mehr nach zehn Tagen ist, Δ ist eine Aufrechterhaltung der Zugfestigkeit von 70% bis 80% nach zehn Tagen, und X ist eine Aufrechterhaltung der Zugfestigkeit von weniger als 70% nach zehn Tagen.

Experimentelle Beispiele 5 bis 9

[0068] Unter Verwendung von Polyesterharzelastomer (Handelsname Perplene EN1000, EN2000, EN3000 und EN5000, hergestellt durch TOYOBO Co., Ltd.) wie in Tabelle 2 aufgelistet als thermoplastisches Harzelastomer, einer Spannung bei 10% Verlängerung A von 54 kgf/cm^2, einer Zugfestigkeit B von 220 kgf/cm^2, einem Biegeelastizitätsmodul C von 1100 kgf/cm^2, einer Beziehung $(A \times B) \div C = 10.8$, wurden 34 Kugeln aus Lagerstahl (SUJ2) mit einer Größe von 3,969 mm ∅ hergestellt als ein Kern durch Spritzgießen, und von der Form gelöst, zusammen mit einer Anzahl von Kugeln, wodurch die Kugel-Störungsverhinderer mit einer Form wie in **Fig.** 8 bis 11 gezeigt geformt wurden.

[0069] Die erhaltenen Kugel-Störungsverhinderer der jeweiligen experimentellen Beispiele 5 bis 9 wurden im Hinblick auf die Dauerhaftigkeit, Gleiteigenschaften, den Verschleißwiderstand, das Wasserabsorptionsvermögen, die Schwelleigenschaften und den Wasserwiderstand auf dieselbe Weise wie in den vorhergehenden experimentellen Beispielen 1 bis 4 untersucht.

[0070] Die Ergebnisse sind nachstehend in Tabelle 2 aufgelistet.

[0071] Mit dem Wälzelement-Störungsverhinderer der vorliegenden Erfindung ist es möglich, mit der Führungsvorrichtung, in die dieser eingebaut ist, in ausgezeichneter Weise geringes Geräusch, Wartungsfreiheit für lange Zeit, hohe Geschwindigkeit und Gleiteigenschaften, und gleichzeitig ausgezeichnete Dauerhaftigkeit und Verschleißwiderstand aufzuweisen, wodurch die Führungsvorrichtung stabil über eine lange Zeit eingesetzt werden kann, um der Verminderung der Abmessungen und der Erhöhung der Geschwindigkeit zu begegnen.

Patentansprüche

1. Wälzelement-Störungsverhinderer für eine Führungsvorrichtung, die einen kontinuierlichen Zirkulationspfad und eine Vielzahl von Wälzelementen besitzt, die unter gleichmäßigen Abständen in dem kontinuierlichen Zirkulationspfad wälzen, worin der Wälzelement-Störungsverhinderer verhindert, dass die Wälzelemente einander stören, und
worin der Wälzelement-Störungsverhinderer aus einem Elastomer aus thermoplastischen Harz gebildet ist, das physikalische Eigenschaften in Übereinstimmung mit einem Ausdruck $(A \times B) \div C \geq 18$ besitzt, wobei A eine Spannung bei 10% Verlängerung darstellt, B eine Zugfestigkeit darstellt, und C einen Biege-Elastizitätsmodul darstellt.
2. Wälzelement-Störungsverhinderer nach Anspruch 1, worin das Elastomer aus thermoplastischen Harz eine Spannung bei 10% Verlängerung A von 60 bis 200 kgf/cm^2 besitzt, eine Zugfestigkeit B von 340 bis 460 kgf/cm^2 und einen Biege-Elastizitätsmodul C von 3000 bis 5000 kgf/cm^2 besitzt.
3. Wälzelement-Störungsverhinderer nach Anspruch 1, worin ein Wasserabsorptionskoeffizient für das Elastomer aus thermoplastischen Harz nicht mehr als 1,5 Gewichts-% beträgt.
4. Wälzelement-Störungsverhinderer nach Anspruch 1, worin ein Schwellfaktor des Elastomers aus thermoplastischem Harz nicht mehr als 3% beträgt.
5. Wälzelement-Störungsverhinderer nach Anspruch 1, worin eine Aufrechterhaltung der Zugfestigkeit des Elastomers aus thermoplastischem Harz nicht weniger als 70% nach zehn Tagen in einem Eintauchversuch in kochendem Wasser bei 100°C beträgt.
6. Führungsvorrichtung, die aufweist:
eine Schiene, die einen Wälzpfad besitzt;
eine Gleitplatte, die eine dem Wälzpfad gegenüberliegende Wälzrille besitzt und sich entlang der Schiene bewegt;
eine Vielzahl von Wälzelementen, die bei einer aufgebrachten Belastung zwischen dem Wälzpfad und der Wälzrille wälzen;
einen Wälzelement-Störungsverhinderer, der einen flexiblen Harzverbinder einschließt, welcher eine Vielzahl eingelegter Abschnitte besitzt, die zwischen den jeweiligen Wälzelementen eingelegt sind, und einen Verbindungsabschnitt zum Verbinden der jeweiligen eingelegten Abschnitte besitzt,
worin der Wälzelement-Störungsverhinderer aus einem Elastomer aus thermoplastischen Harz gebildet ist, das physikalische Eigenschaften in Übereinstimmung mit einem Ausdruck $(A \times B) \div C \geq 18$ besitzt, wobei A eine Spannung bei 10% Verlängerung darstellt, B eine Zugfestigkeit darstellt, und C einen Biege-Elastizitätsmodul darstellt.

7. Führungsvorrichtung nach Anspruch 6, worin der Harzverbinder die Wälzelemente in einem angeordneten Zustand und wälzbar mittels der eingelegten Abschnitte und des verbindenden Abschnitts trägt.

8. Führungsvorrichtung nach Anspruch 6, worin die Wälzelemente Kugeln sind, und das Elastomer aus thermoplastischem Harz besitzt eine Spannung bei 10% Verlängerung A von 60 bis 100 kgf/cm^2, eine Zugfestigkeit B von 340 bis 400 kgf/cm^2, und einen Biege-Elastizitätsmodul C von 1000 bis 2000 kgf/cm^2.

9. Führungsvorrichtung nach Anspruch 6, worin die Wälzelemente Walzen sind, und das Elastomer aus thermoplastischem Harz besitzt eine Spannung bei 10% Verlängerung A von 80 bis 200 kgf/cm^2, eine Zugfestigkeit B von 380 bis 400 kgf/cm^2, und einen Biege-Elastizitätsmodul C von 2000 bis 5000 kgf/cm^2.

10. Führungsvorrichtung, die aufweist:
eine Kugelumlaufspindel, die einen spiralförmigen Wälzpfad besitzt;
eine Mutter, die eine spiralförmige Wälzrille besitzt, die dem spiralförmigen Wälzpfad gegenüberliegt;
eine Vielzahl von Kugeln, die zwischen dem spiralförmigen Wälzpfad und der spiralförmigen Wälzrille wälzen; und
einen Kugel-Störungsverhinderer,
worin der Kugel-Störungsverhinderer eine Vielzahl von Abstandhaltern aufweist, die zwischen den jeweiligen Kugeln eingelegt sind, und
worin der Kugel-Störungsverhinderer aus einem Elastomer aus thermoplastischem Harz gebildet ist, das physikalischen Eigenschaften in Übereinstimmung mit einem Ausdruck $(A \times B) \div C \geq 18$ besitzt, wobei A eine Spannung bei 10% Verlängerung darstellt, B eine Zugfestigkeit darstellt, und C einen Biege-Elastizitätsmodul darstellt.

(54) Wälzführungsvorrichtung und Walzenverbindungskörper

(57) Eine Wälzführungsvorrichtung schließt ein eine Schiene, die Walzenlaufflächen besitzt, und einen Walzenzirkulationspfad, der Lastwalzenlaufflächen entsprechend zu den Walzenlaufflächen besitzt, einschließt, und eine Vielzahl von Walzen, die in dem Walzenzirkulationspfad angeordnet und aufgenommen sind und in Assoziation mit einer Bewegung eines beweglichen Blocks gegenüber der Schiene zirkulieren. Jede Walze besitzt ein Verhältnis von näherungsweise 1,5 < L/Da < näherungsweise 3. Durch Einstellen des Verhältnisses der Walzenlänge zum Walzendurchmesser auf einen Wert von näherungsweise 1,5 < L/Da wird die grundlegende statische Belastungsbewertung einer Wälzführungsvorrichtung des Walzentyps größer als diejenige einer Wälzführungsvorrichtung des Kugeltyps, wenn die Teile der Vorrichtungen vom selben Modell sind. Durch Einstellen des Verhältnisses auf einen Wert von L/Da < näherungsweise 3, wird das Auftreten einer Schrägstellung ohne Ausfall verhindert, ohne Anwenden einer strengen Abmessungskontrolle des Axialspalts.

Beschreibung

HINTERGRUND DER ERFINDUNG

1. Technisches Gebiet der Erfindung

[0001] Die vorliegende Erfindung bezieht sich auf eine Wälzführungsvorrichtung, die Walzen besitzt, welche eine Wälzbewegung ausführen und zwischen einer Laufringwelle und einem beweglichen Element eingelegt sind, sowie auf ein Walzenverbindungselement zum Halten der Walzen in rotierbarer und gleitbarer Weise.

2. Beschreibung des Standes der Technik

[0002] Eine Wälzführungsvorrichtung weist auf eine Schiene; einen beweglichen Block, der beweglich entlang der Schiene über eine Vielzahl von Wälzelementen vorgesehen ist; und eine Vielzahl von Walzen, die zwischen der Schiene und dem beweglichen Block eingelegt sind. **Fig.** 1 zeigt eine Wälzführungsvorrichtung, die Walzen darin aufgenommen besitzt. Wenn sich ein beweglicher Block **101** gegenüber einer Schiene **104** bewegt hat, führen Walzen **100**, die in einem zwischen zwei Walzenlaufringflächen **102** definierten Lastbereich angeordnet sind, eine Wälzbewegung aus, um dabei in einem nicht belasteten Bereich B angeordnete Walzen **100** zu schieben. Dann werden die in dem nicht belasteten Bereich B angeordneten Rollen **100** in den Lastbereich A auf der verbleibenden Seite geschoben. Somit zirkulieren die Walzen **100** durch einen Walzenzirkulationspfad, der entlang des beweglichen Blocks **101** definiert ist.

[0003] Ein Ball besitzt die Form einer Kugel und enthält eine unendliche Anzahl von Rotationsachsen. Daher kann sich der Ball in jegliche Richtung bewegen, je nachdem wie es die Umstände erfordern. Da die Walzen **100** zylindrisch sind, besitzt jede Walze **100** lediglich eine Rotationsachse, und daher ist die Bewegungsrichtung der Walze **100** auf lediglich eine Richtung begrenzt. Die Rotationsachse der Walze und die Bewegungsrichtung derselben müssen einen rechten Winkel aufrechterhalten. In Bezug auf eine Linearbewegungsführungsvorrichtung, welche die Walzen **100** verwendet, falls die Walzenlaufringfläche **102** des beweglichen Blocks **100** aus der Parallelen mit der Walzenlaufringfläche **102** der Schiene **104** geraten ist oder falls eine Aufsetz-Belastung auf den beweglichen Block **100** gewirkt hat, kann eine Möglichkeit entstehen, dass die Rotationsachse **105** der Walze **100** und die Bewegungsrichtung derselben aus einem rechten Winkel herausfallen, wie in **Fig.** 2 dargestellt. Ein derartiges Phänomen, in welchem die Walzen **100** gegenüber der normalen Rotationsachse geneigt sind, wird als "Schrägstellung" ("skew") bezeichnet. In dem Fall einer Linearbewegungsführungseinrichtung eines Typs ausschließlich mit Walzen, in welcher eine Vielzahl von ausschließlich Walzen **100** in dem Walzenzirkulationspfad eingeschlossen sind, kommen die Endflächen der entsprechend Walzen **100**, die in der Richtung der Rotationsachse liegen, in Kontakt mit einem Flansch **103**, der auf dem beweglichen Block **101** gebildet ist, wodurch das Auftreten eines Schrägstellens der Walzen **100** verhindert wird.

[0004] Falls Belastung auf die Linearbewegungs-Wälzelemente wirkt, werden der bewegliche Block **101** oder die Schiene **104** elastisch verformt. Das Ausmaß, in welchem die Wälzelemente, der bewegliche Block **101** oder die Schiene **104** Verformung widerstehen, wird als Steifigkeit der Linearbewegungsführungseinrichtung bezeichnet. Eine Linearbewegungsführungseinrichtung, in welcher Walzen als Wälzelemente aufgenommen sind, besitzt im allgemeinen eine größere Steifigkeit als die Linearführungseinrichtung, in welcher Kugeln als Wälzelemente eingesetzt sind. Die Steifigkeit der Linearbewegungsführungseinrichtung, die Walzen darin aufgenommen besitzt, wird anhand der Walzen **100** und der axialen Länge derselben bestimmt. Je größer die Anzahl von Walzen **100** und je länger ihre axiale Länge ist, desto größer ist die Steifigkeit der Linearbewegungsführungsvorrichtung. In anderen Worten, die Aufnahme einer großen Anzahl langgestreckter Rollen in die Linearbewegungsführungsvorrichtung ist effektiv zum Erhöhen der Steifigkeit derselben.

[0005] Wenn langgestreckte Walzen zum Verbessern der Steifigkeit verwendet werden, kann kein großer Kontaktbereich zwischen der Endfläche der Walze **100** und dem Flansch **103** in Bezug auf die Länge der Walze **100** in einer Rotationsrichtung davon sichergestellt werden. Daher kann eine Schrägstellung in den Walzen **100** auftreten. Dementsprechend können Probleme entstehen; das heißt, ein Phänomen, dass Walzen nicht mehr rotieren können (d. h. ein Blokkierphänomen), ein Erhitzungsphänomen, oder ein Phänomen eines Tischoszillierens aus Gründen von Vibration, das auftritt, wenn die Walzen in dem belasteten Bereich angeordnet sind (d. h. ein Wellenphänomen).

ZUSAMMENFASSUNG DER ERFINDUNG

[0006] Die vorliegende Erfindung dient zum Bereitstellen einer Wälzführungsvorrichtung und eines Walzenverbindungselements, die zuverlässig das Auftreten einer Schrägstellung der Walzen verhindern können und die Steifigkeit verbessern. Zum Lösen der obigen Aufgabe wird gemäß einer Zielrichtung der Erfindung eine Wälzführungsvorrichtung bereitgestellt, die aufweist:
eine Laufringwelle, die Walzlaufringflächen besitzt,
ein bewegliches Element, das Walzenzirkulationspfade besitzt, die Lastwalzenlaufringflächen entsprechend den jeweiligen Walzenlaufringflächen einschließen und an der Laufringwelle in relativ beweglicher Weise befestigt sind; und
eine Vielzahl von Walzen, die in den Walzenzirkulationspfaden angeordnet und aufgenommen sind und in Assoziation mit einer Bewegung der beweglichen Elemente gegenüber der Laufringwelle zirkulieren,
worin die Walzen derart gebildet sind, um eine Beziehung von näherungsweise $1{,}5 < L/Da <$ näherungsweise 3 zu erfüllen, wobei der Durchmesser der Walze als Da definiert ist, und die Länge der Walze entlang einer Richtung einer Rotationsachse davon als L angenommen ist.

[0007] Gemäß einer zweiten Zielrichtung der Erfindung sind in der Wälzführungsvorrichtung gemäß der ersten Zielrichtung die Vielzahl von Walzen derart angeordnet, dass die Rotationsachsen der Walzen parallel zueinander gebracht sind; die Wälzführungsvorrichtung besitzt einen Walzenhalter zum rotierbaren und gleitbaren Halten der Vielzahl von Walzen; und der Walzenhalter besitzt eine Vielzahl von Abstandhaltern, die jeweils zwischen den Walzen eingelegt sind, und flexible Verbindungsabschnitte zum gegenseitigen Verbinden der Abstandhalter.

[0008] Gemäß einer dritten Zielrichtung der Erfindung ist in der Wälzführungsvorrichtung gemäß der zweiten Zielrichtung eine mit Vertiefungen versehene Oberfläche, die zu der Geometrie der äußeren Oberfläche jeder der Walzen passt, auf jeder Seite der Abstandhalter gebildet.

[0009] Gemäß einer vierten Zielrichtung der Erfindung ragen in der Wälzführungsvorrichtung gemäß der zweiten Zielrichtung die Verbindungsabschnitte seitlich von den Endflächen der Walzen in Bezug auf die Richtung der Rotationsachsen heraus.

[0010] Gemäß einer fünften Zielrichtung der Erfindung sind in der Wälzführungsvorrichtung gemäß dem zweiten Aspekt die Führungsabschnitte entlang der Walzenzirkulationspfade des beweglichen Elements gebildet.

[0011] Gemäß einer sechsten Zielrichtung der Erfindung wird ein Walzenverbindungselement bereitgestellt, das aufweist:

einen Walzenhalter, der einschließt:

eine Vielzahl von Walzen, die derart anzuordnen sind, dass die Rotationsachsen der Walzen parallel zueinander gebracht sind; und

einen Walzenhalter, der eine Vielzahl von Abstandhaltern besitzt, die jeweils zwischen den Walzen eingelegt sind, und flexible Verbindungsabschnitte zum gegenseitigen Verbinden der Abstandhalter, worin die Walzen derart gebildet sind, um eine Beziehung von näherungsweise 1,5c L/Da < näherungsweise 3 zu erfüllen, wobei der Durchmesser der Walze als Da definiert ist, und die Länge der Walze entlang einer Richtung einer Rotationsachse als L angenommen ist.

[0012] Gemäß einer siebten Zielrichtung der Erfindung ist in dem Walzenverbindungselement gemäß der sechsten Zielrichtung eine mit Vertiefungen versehene Oberfläche auf jede Seite der Abstandhalter gebildet, die zu der Geometrie der äußeren Oberfläche jeder der Walzen passt.

[0013] Gemäß einer achten Zielrichtung der Erfindung ragen in dem Walzenverbindungselement die Verbindungsabschnitte seitlich von den Endflächen der Walzen in Bezug auf die Richtung der Rotationsachsen heraus.

KURZE BESCHREIBUNG DER ZEICHNUNGEN

[0014] **Fig.** 1 ist eine Querschnittsansicht, welche eine Linearbewegungsführungsvorrichtung zeigt, die Walzen des Standes der Technik darin aufgenommen besitzt;

[0015] **Fig.** 2 ist eine schematische Darstellung, welche Walzen zeigt, die eine Schrägstellung aufweisen;

[0016] **Fig.** 3 ist eine Ansicht, die einen Zustand zeigt, in welchem eine effektive Länge L der Walzen derart eingestellt ist, um im wesentlichen gleich einem Durchmesser Db einer Kugel unter Anforderung 1 zu sein;

[0017] **Fig.** 4 ist eine Querschnittsansicht, welche eine Wälzführungsvorrichtung des Kugeltyps zeigt, die ein Vergleichsobjekt unter Anforderung 2 ist;

[0018] **Fig.** 5 ist ein Graph, der eine grundlegende statische Belastungsbewertung Co einer Wälzführungsvorrichtung des Walzentyps und eine grundlegende statische Belastungsbewertung Co einer Wälzführungsvorrichtung des Kugeltyps zeigt, wenn L/Da auf ein Wert von 1,5 eingestellt ist;

[0019] **Fig.** 6a und 6b sind Veranschaulichungen, welche Werte zeigt, die in einem Ausdruck zum Berechnen eines Schrägstellungswinkels verwendet werden (worin **Fig.** 6a eine Seitenansicht einer Walze ist; und **Fig.** 6b eine Draufsicht der Walze ist);

[0020] **Fig.** 7 ist ein Graph, dessen horizontale Achse durch $\Delta L/L(=\zeta)$ und dessen vertikale Achse durch einen Schrägstellungswinkel β dargestellt ist;

[0021] **Fig.** 8 ist eine perspektivische Explosionsansicht, die eine Linearbewegungsführungsvorrichtung gemäß einer ersten Ausführungsform der Erfindung zeigt;

[0022] **Fig.** 9 ist eine Seitenansicht der Linearbewegungsführungsvorrichtung, welche teilweise eine Querschnittsansicht derselben senkrecht zu der Längsrichtung einschließt;

[0023] **Fig.** 10a und 10b zeigen eine Walze, die durch einen Walzenzirkulationspfad zirkuliert, worin **Fig.** 10a einen in dem belasteten Bereich angeordneten Walzenzirkulationspfad zeigt, und **Fig.** 10b einen in den nicht belasteten Bereich angeordneten Walzenzirkulationspfad zeigt;

[0024] **Fig.** 11a und 11b zeigen ein Verhältnis des Walzendurchmessers zu der Walzenlänge, worin **Fig.** 11a einen Zustand zeigt, in welchem L/Da einen Wert von 1,5 annimmt, und **Fig.** 11b einen Zustand zeigt, in welchem L/Da einen Wert von 3 annimmt;

[0025] **Fig.** 12a und 12b zeigen einen Schrägstellungswinkel einer Walze, worin **Fig.** 12a eine Walze gemäß der Ausführungsform zeigt, und **Fig.** 12b eine nadelförmige Walze zeigt; und

[0026] **Fig.** 13a bis 13c sind Ansichten, die einen Walzenhalter zeigen, worin **Fig.** 13a eine Draufsicht ist, **Fig.** 13b eine Seitenansicht ist, und **Fig.** 13c eine Frontansicht ist.

AUSFÜHRLICHE BESCHREIBUNG BEVORZUGTER AUSFÜHRUNGSFORMEN

[0027] Nachfolgend wird eine ausführlichere Beschreibung bevorzugter Ausführungsformen der Erfindung unter Bezugnahme auf die begleitenden Zeichnungen gegeben.

[0028] Um ein besseres Verständnis der vorliegenden Erfindung zu ermöglichen, sind die in den begleitenden Zeichnungen vorgesehenen Bezugszeichen mit Elementen assoziiert und in der Beschreibung in Klammern angegeben. Allerdings begrenzen die Bezugszeichen die Erfindung nicht auf die veranschaulichten Ausführungsformen.

[0029] Der Erfinder hat festgestellt, dass das Auftreten einer Schrägstellung von Walzen zuverlässig verhindert werden kann und dass die Steifigkeit einer Wälzbewegungsführungsvorrichtung verbessert werden kann mittels Festlegens eines Verhältnisses der Länge einer Walze in einer Rotationsrichtung davon zu dem Durchmesser der Walze in einen vorbestimmten Bereich.

[0030] Genauer gesagt weist eine Wälzführungsvorrichtung gemäß einer ersten Zielrichtung der Erfindung auf:

eine Laufringwelle **1**, die Walzenlaufringflächen **1**b besitzt, und ein bewegliches Element **2**, das Walzenzirkulationspfade besitzt, die Lastwalzenlaufringflächen **4**d entsprechend den jeweiligen Walzenlaufringflächen **1**b einschließen und an der Laufringwelle **1** in relativ beweglicher Weise befestigt sind; und

eine Vielzahl von Walzen **3**, die in den Walzenzirkulationspfaden angeordnet und aufgenommen sind und in Assoziation mit einer Bewegung des beweglichen Elements **2** gegenüber der Laufringwelle **1** zirkulieren. Die Walzen **3** sind hier derart gebildet, um ein Verhältnis von näherungsweise 1,5 < L/Da < näherungsweise 3 zu erfüllen, wobei der Durchmesser der Walzen **3** als Da definiert ist und die Länge der Walze **3** in einer Richtung der Rotationsachse davon als L angenommen ist.

[0031] Die Gründe für das Definieren eines Verhältnisses der Walzenlänge zu dem Walzendurchmesser auf einen Wert von näherungsweise 1,5 < L/Da werden nachfolgend beschrieben. Eine grundlegende statische Belastungsbewertung einer Wälzführungsvorrichtung, die Walzen als Wälzelemente verwendet (d. h. eine Wälzführungsvorrichtung des Walzentyps) und diejenige einer Wälzführungsvorrichtung, die Kugeln als Wälzelemente verwendet, wird bestimmt, während L/Da auf verschiedene Werte verändert wird, vorausgesetzt, dass beide Wälzführungsvorrichtungen vom selben Modell sind. Hier bezieht sich die grundlegende statische Belastungsbewertung auf eine Last, bei welcher der Gesamtbetrag der Verformung, der in den Wälzelementen auftritt, der in dem beweglichen Element auftritt und der in der Laufringwelle auftritt, eine Toleranzgrenze erreicht. Eine Berechnungsgleichung für die Wälzführungsvorrichtung des Walzentyps und eine Berechnungsgleichung für die Wälzführungsvorrichtung des Kugeltyps werden angewendet, und Anforderungen für die Gleichungen sind wie folgt.

Anforderung 1

[0032] In Bezug auf die Wälzführungsvorrichtung des Walzentyps und die Wälzführungsvorrichtung des Kugeltyps wird die effektive Länge L der Walze derart eingestellt, um im wesentlichen gleich zu dem Durchmesser Db der Kugel zu sein, wie in **Fig.** 3 dargestellt. Der allgemeine Grund für dies ist wie folgt. Die Abmessung des beweglichen Blocks, der als bewegliches Element dient, wird auf einen vorbestimmten Wert für jedes Modell ungeachtet der Art des Wälzelements (d. h. Walze oder Kugel) eingestellt. In dem Fall einer Kugel wird der Durchmesser Db der Kugel innerhalb eines Bereichs der Abmessungen des beweglichen Blocks auf eine maximale Abmessung eingestellt, bei welcher eine Bewegung der Kugel, wie eine Richtungsänderung, möglich wird. Weiter sind in dem Fall einer Walze die Länge L und der Durchmesser Da der Walze auf maximale Abmessungen eingestellt, bei welchen eine Bewegung der Walze, wie eine Richtungsänderung, möglich wären. Falls ein Versuch unternommen wird, die Kugel und die Walze maximaler Abmessungen in den beweglichen Block des identischen Modells einzufügen, wird ein Verhältnis von $L \approx Db$ unvermeidlich erhalten.

Anforderung 2

[0033] Es wurde eine Wälzführungsvorrichtung des Walzentyps beschrieben in Verbindung mit einer in **Fig.** 8 und 9 gezeigten Ausführungsform verwendet. Als zu vergleichende Wälzführungsvorrichtungen des Kugeltyps wurde eine Wälzführungsvorrichtung mit einer Struktur wie der in **Fig.** 4 dargestellten verwendet. Die Wälzführungsvorrichtung ist von Kugeltyp und wurde vom Anmelder entwickelt (vom Anmelder als Modell NRS bezeichnet), um dieselbe Steifigkeit wie diejenige einer Wälzführungsvorrichtung des Walzentyps aufzuweisen. Von allen Teilen handelsüblich erhältlicher Wälzführungsvorrichtungen, einschließlich der Produkte anderer Herstellungsfirmen, besitzt die Wälzführungsvorrichtung die maximale grundlegende statische Belastungsbewertung.

[0034] Die schematische Konstruktion der Wälzführungsvorrichtung des Kugeltyps wird nachfolgend beschrieben. Zwei Reihen von Kugeln **112** sind zwischen einer unteren Fläche des beweglichen Blocks **110** und einer oberen Fläche der Schiene **111** definiert. Weiter ist eine Gesamtheit von zwei Reihen von Kugeln **113** auf den jeweiligen Seiten der Schiene **111** vorgesehen und ist definiert zwischen einer inneren Seitenfläche des beweglichen Blocks **110** und einer äußeren Seitenfläche der Schiene **111**. Die Wälzführungsvorrichtung ist dadurch gekennzeichnet, dass eine Kugellaufrille **110**a des beweglichen Blocks **110** und eine Kugellaufrille **111**a der Schiene **111** mit ausreichender Tiefe gebildet sind, um die schwere Last aufzunehmen. Eine Kontaktlinie **116** ist definiert durch Verbinden des Mittelpunkts der Kugel **114** mit einem Kontaktpunkt, der zwischen der Kugel **114** und der Kugellaufrille **110**a des beweglichen Blocks **110** vorhanden ist. In ähnlicher Weise ist eine Kontaktlinie **117** definiert durch Verbinden des Mittelpunkts der Kugel **114** mit einem Kontaktpunkt, der zwischen der Kugel **114** und der Kugellaufrille **111**a der Schiene **111** vorhanden ist. Die Kontaktlinien **116** und **117** sind jeweils so eingestellt, um einen Winkel von 45° gegenüber ein horizontalen Linie einzunehmen. Somit können die Kugel **114** gleichzeitig radiale Belastung, umgekehrt radiale Belastung und horizontale Belastung aufnehmen.

[0035] Die grundlegende statische Belastungsbewertung der Wälzführungsvorrichtung des Walzentyps wird bestimmt durch Verwendung einer Berechnungsgleichung für den Kugeltyp, während L/Da auf verschiedene Werte verändert wird. Weiter wird die grundlegende statische Belastungsbewertung der Wälzführungsvorrichtung des Kugeltyps bestimmt durch Verwendung einer Berechnungsgleichung für den Kugeltyp während L/Da auf verändert wird. Dementsprechend wird festgestellt, dass die grundlegende statische Belastungsbewertung der Wälzführungsvorrichtung des Walzentyps diejenige der Wälzführungsvorrichtung des Kugeltyps an einer Grenze überschreitet, bei welcher L/Da 1,5 ist.

[0036] **Fig.** 5 ist ein Graph, der ein Vergleich zwischen der grundlegenden statischen Belastungsbewertung Co der Wälzführungsvorrichtung des Walzentyps und der grundlegenden statischen Belastungsbewertung Co der Wälzführungsvorrichtung des Kugeltyps zeigt, wenn L/Da einen Wert von 1,5 erreicht hat. Wie anhand von **Fig.** 5 ersichtlich ist, vorausgesetzt, dass L/Da einen Wert von 1,5 annimmt, überschreitet die grundlegende statische Belastungsbewertung Co der Wälzführungsvorrichtung des Walzentyps diejenige der Wälzführungsvorrichtung des Kugeltyps unter Berücksichtigung aller Modelle. Im Gegensatz hierzu, wenn L/Da zu einem Wert von 1,5 oder weniger angenommen wird, ist festzustellen, dass die grundlegende statische Beanspruchungsbewertung Co der Wälzführungsvorrichtung des Walzentyps geringer ist als diejenige der Wälzführungsvorrichtung des Kugeltyps, was die Verwendung von Walzen bedeutungslos macht.

[0037] Somit wird durch Einstellen des Verhältnisses der Walzenlänge zu dem Walzendurchmesser auf einen Wert von näherungsweise 1,5 < L/Da die grundlegende statische Belastungsbewertung Co der Wälzführungsvorrichtung des Walzentyps größer als diejenige der Wälzführungsvorrichtung des Kugeltyps, wenn die Teile der Vorrichtungen von demselben Modell sind. Somit wird die Eignung der Verwendung von Walzen, d. h. eine Erhöhung der Steifigkeit der Walzen, erzielt.

[0038] Als nächstes werden die Gründe für das Einstellen des Verhältnisses der Walzenlänge zu dem Walzendurchmesser auf einen Wert von L/Da < näherungsweise 3 beschrieben. Unter Berücksichtigung, dass die Walzen angeschrägt worden sind, ist ein Schrägstellungswinkel β, bei welchem die Walzen gegenüber der normalen Rotationsachse geneigt sind, durch nachstehende Gleichung 1 definiert

$$\beta = \sin^{-1}\left[\frac{2bL(1+\xi) - \sqrt{(2bL(1+\xi))^2 - 8\xi L^2(L^2+b^2)}}{2(L^2+b^2)}\right] \qquad (1)$$

[0039] Wie in **Fig.** 6a und 6b dargestellt, bezeichnet L die Länge einer Walze; L + ΔL bezeichnet die Breite einer Rille; b bezeichnet die Breite eines Kontaktbereichs, der zwischen der Walze und einem Flansch vorhanden ist, wenn die Walze im engen Kontakt mit dem Flansch gebracht wird; und ξ = ΔL durch L ≈ 0,01 bis 0,1. Durch Verwendung der oben beschriebenen Gleichung zum Berechnen eines Winkels kann ein Graph aufgetragen werden, dessen horizontale Achse ΔL durch L (= ζ) darstellt und dessen vertikale Achse einen Schrägstellungswinkel Δ darstellt, während L/Da auf verschiedene Werte verändert wird, wie in **Fig.** 7 dargestellt (wobei Da = 2b). Der Wert von L/Da wurde auf 1,5, 3 und 4 verändert.

[0040] Wie anhand von **Fig.** 7 ersichtlich ist, wird die Veränderungsrate von ΔL/L-β plötzlich hoch bei einem Bremswert von L/Da ≈ 3. Wenn L/Da einen Wert von 4 annimmt, verändert sich der Schrägstellungswinkel stark von einem Winkel von etwa 6° auf ein Winkel von etwa 10°, wenn ΔL/L von einem nominalen Wert von etwa 0,02 auf einen Wert von etwa 0,025, d. h. um einen Wert von 0,005 anwächst. Somit muss, um den Schrägstellungswinkel zu unterdrücken, der axiale Spalt ΔL sehr streng gesteuert werden, wodurch ein Problem eines Kostenanstieges entsteht. Dem gegenüber, falls L/Da auf einen Wert von näherungsweise 3 oder weniger eingestellt ist, wird eine Veränderungsrate von ΔL/L-β vergleichsweise niedrig ausfallen. Selbst wenn eine geringfügige Abweichung beim Einstellen von ΔL entsteht, wird der Schrägstellungswinkel nicht allzu stark beeinflusst. In anderen Worten, die Genauigkeit der Dimensionssteuerung des axialen Spalts ΔL kann vermindert werden, indem L/Da auf einen Wert von näherungsweise 3 oder weniger eingestellt wird.

[0041] Das Auftreten einer Schrägstellung kann zuverlässig verhindert werden, ohne Anwendung eines sehr genauen Abmessungsmanagements des axialen Spalts ΔL mittels Einstellen von L/Da auf weniger als näherungsweise 3. Weiterhin gibt es keine Notwendigkeit einer sehr strengen Dimensionsüberwachung des axialen Spalts ΔL. Somit können die Kosten der Wälzführungsvorrichtung begrenzt werden.

[0042] Gemäß einer zweiten Zielrichtung der Erfindung ist die Vielzahl von Walzen **3** derart angeordnet, dass die Rotationsachsen der Walzen parallel zueinander gebracht sind. Die Wälzführungsvorrichtung besitzt einen Walzenhalter **10** zum rotierbaren und gleitbaren Halten der Vielzahl von Walzen **3**. Weiter besitzt der Walzenhalter **10** eine Vielzahl von Abstandhaltern **46**, die jeweils zwischen den Walzen **3** eingelegt sind, und flexible Verbindungsabschnitte **47** zum gegenseitigen Verbinden der Abstandhalter **46**.

[0043] Gemäß der Erfindung, da die Walzenhalter **10** die Walzen in einer vorbestimmten Position ausrichten, kann das Auftreten einer Schrägstellung der Walzen **3** verhindert werden. Selbst wenn eine Schrägstellung entstanden ist korrigiert der Walzenhalter **10** die Schrägstellung der Walzen **3** derart, dass jede der Walzen **3** wiederum eine vorbestimmte Rotationsachse einnimmt mittels einer elastischen Rückstellkraft der Verbindungsabschnitte **47**. Somit besitzt der Walzenhalter **10** die Wirkung des Ausrichtens der Walzen **3** in eine vorbestimmte Position und die Wirkung des Verhinderns der Akkumulation der Schrägstellung der Walzen **3**. Die Kooperation mit der Wirkung, die durch Einstellen des Verhältnisses des Walzendurchmessers zu der Walzenlänge auf L/Da < näherungsweise 3 erzielt wird, verhindert die Verwendung des Walzenhalters **10** zuverlässig das Auftreten einer Schrägstellung der Walzen **3**.

[0044] Gemäß einer dritten Zielrichtung der Erfindung ist eine mit Vertiefungen versehene Oberfläche **49**, die zu der Geometrie der äußeren Oberfläche jeder der Walzen **3** passt, auf jeder Seite der Abstandhalter **46** gebildet.

[0045] Gemäß der Erfindung, als Ergebnis der mit Vertiefungen versehenen Oberflächen **49**, welche die Walzen **3** halten, kann ein Entfernen der Walzen **3** aus dem Walzenhalter **10** verhindert werden; d. h. ein bewegliches Element **2**, das andernfalls veranlasst sein würde, wenn das bewegliche Element **2** von der Laufringwelle **1** entfernt wird. Weiterhin wird eine ausreichende Menge von Schmiermittel in einem zwischen der mit Vertiefungen versehenen Oberfläche **49** und der Walze **3** definierten Raum gesammelt, wodurch eine ausreichende Schmierwirkung erzielt wird.

[0046] Gemäß einer vierten Zielrichtung der Erfindung ragen die Verbindungsabschnitte **47** seitlich von den Endflächen der Walzen **3** in Bezug auf die Richtung der Rotationsachse hervor.

[0047] Gemäß einer fünften Zielrichtung der Erfindung sind Führungsabschnitte (**11**a, **12**a, **13**a und **20**a) entlang der Walzenzirkulationspfade des beweglichen Elements **2** gebildet.

[0048] In dieser Beschreibung bezieht der Begriff "Führung" bevorzugt auf den folgenden Zustand.

[0049] Ein Spalt geringer Abmessung ist zwischen den Verbindungsabschnitten **47** des Walzenhalters **10** und den Führungsabschnitten **11**a, **12**a, **13**a und **20**a gebildet. Falls der Walzenhalter **10** sich verzogen hat oder seine Richtung geringfügig geändert hat, geraten die Verbindungsabschnitte **47** in Kontakt mit einer Wandfläche der Führungsabschnitte **11**a, **12**a, **13**a und **20**a. In anderen Worten, bleiben die Verbindungsabschnitte **47** nicht die gesamte Zeit in Kontakt mit den Führungsabschnitten **11**a, **12**a, **13**a und **20**a. Die Wälzführungsvorrichtung kann derart konstruiert sein, dass die Verbindungsabschnitte **47** stets in Kontakt mit den Führungsabschnitten **11**a, **12**a, **13**a und **20**a bleiben. Allerdings unterdrückt der Spalt, der zwischen den Verbindungsabschnitten **47** und den Führungsabschnitten **11**a, **12**a, **13**a und **20**a vorhanden ist, den Kontaktwiderstand, der dazwischen auftreten wird, wodurch der Bewegungswiderstand des beweglichen Elements **2** vermindert wird.

[0050] Gemäß der Erfindung ist der Walzenhalter **10** derart geführt, um einen vorbestimmten Pfad in dem Walzenzirkulationspfad mittels der Führungsabschnitte **11**a, **12**a, **13**a und **20**a aufrechtzuerhalten. Dementsprechend halten die durch den Walzenhalter **10** gehaltenen Walzen ebenso einen vorbestimmten Pfad ein, und somit kann das Auftreten einer Schrägstellung der Walzen **3** mit wesentlich größerer Zuverlässigkeit verhindert werden.

[0051] Gemäß einer sechsten Zielrichtung der Erfindung kann die Erfindung als Walzenverbindungselement gebildet sein. Das Walzenverbindungselement besitzt einen Walzenhalter **10**, welcher Halter aufweist:
eine Vielzahl von Walzen **3**, die derart angeordnet sind, dass die Rotationsachsen der Walzen parallel zueinander gebracht sind;
eine Vielzahl von Abstandhaltern **46**, von denen jeder zwischen den Walzen **3** eingelegt ist und auf jeder Seite davon eine mit Vertiefungen versehene Oberfläche **49** besitzt, die zu der Geometrie der äußeren Umfangsfläche einer benachbarten Walze **3** passt; und
flexible Verbindungsabschnitte **47** zum miteinander verbinden der Abstandshalter **46**, wobei die Walzen **3** derart gebildet sind, um keine Beziehung von näherungsweise 1,5 < L/Da < näherungsweise 3 zu erfüllen, wobei der Durchmesser der Walze **3** als Da definiert ist und die Länge der Walze **3** in einer Richtung der Rotationsachse davon als L angenommen ist.

[0052] Gemäß einer siebten Zielrichtung der Erfindung ist eine mit Vertiefungen versehene Oberfläche **49**, die zu der Geometrie der äußeren Oberfläche jeder der Walzen **3** passt, auf beiden Seiten der Abstandshalter **46** gebildet.

[0053] Gemäß einer achten Zielrichtung der Erfindung ragen die Verbindungsabschnitte **47** seitlichen von den Endflächen der Walzen in Bezug auf die Richtung der Rotationsachsen hervor.

[0054] Nachfolgend wird eine ausführlichere Beschreibung bevorzugter Ausführungsformen der Erfindung unter Bezugnahme auf die begleitenden Zeichnungen gegeben.

[0055] **Fig.** 8 und 9 zeigen Linearbewegungsführungsvorrichtungen, die als Wälzführungsvorrichtungen gemäß einer ersten Ausführungsform der Erfindung dienen. **Fig.** 8 ist eine perspektivische Explosionsansicht der Linearbewegungsführungsvorrichtung, und **Fig.** 9 stellt eine Seitenansicht einer zusammengesetzten Linearbewegungsführungsvorrichtung und eine Querschnittsansicht der Vorrichtung in einem Schnitt entlang einer Richtung senkrecht zu der Längsrichtung der Schiene bereit. Die Linearbewegungsführungsvorrichtung besitzt eine Schiene **1**, die als sich linear erstreckende Schiene dient, und einen beweglichen Block **2**, der als bewegliches Element dient, das beweglich mit der Schiene **1** über eine Vielzahl von Walzen **3**, die als Wälzelemente wirken, verbunden ist.

[0056] Die Schiene **1** ist schmal und länglich, um ein rechteckiges Querschnittsprofil anzunehmen. Eine Rille **1**a, die ein v-förmiges Querschnittsprofil besitzt, ist auf beiden Seitenflächen der Schiene **1** gebildet, um sich in Längsrichtung zu erstrecken. Wie in **Fig.** 9 dargestellt besitzt die Rille **1**a Seitenflächen **1**b, und eine Bodenfläche **1**c. Die Wandflächen **1**b, **1**b der Rille **1**a kreuzen einander unter einem Winkel von 90°. Hier werden obere und untere Wandflächen **1**b als Walzenlaufflächen **1**b, **1**b verwendet, auf welchen die Walzen **3** wälzen sollen. Die Walzenlaufflächen **1**b, **1**b sind vertikal auf beiden Seiten der Schiene **1** vorgesehen; insgesamt sind vier Walzenlaufflächen **1**b auf der Schiene **1** gebildet.

[0057] Der bewegliche Block **2** besitzt einen horizontalen Abschnitt **2**a, der einer oberen Fläche der Schiene **1** gegenüberliegt, und Hülsenabschnitte **2**b, die sich nach unten von entsprechenden Seiten der horizontalen Abschnitte **2**a erstrecken und der rechten und linken Seitenfläche der Schiene **1** gegenüberliegen. Zwei Walzenzirkulationspfade, die vertikal in einer Reihe angeordnet sind, sind in jedem des rechten und linken Hülsenabschnitts **2**b gebildet. Insgesamt sind vier Walzenzirkulationspfade gebildet (siehe **Fig.** 9).

[0058] Zunächst werden die Walzenzirkulationspfade beschrieben. Wie in **Fig.** 9 dargestellt, sind zwei Lastwalzenlaufflächen **4**d, die vertikal in einer Reihe angeordnet sind, in jedem der Hülsenabschnitte **2**b des beweglichen Blocks **2** gebildet. Ein zwischen den Lastwalzenlaufflächen **4**d und den Walzenlaufflächen **1**b definierter Raum bildet einen Lastbereich der Walzenzirkulationspfade.

[0059] Zwei Walzenstützpfade **7**, die vertikal in einer Reihe angeordnet sind, sind in entsprechenden Hülsenabschnitten **2**b derart gebildet, um unter einem vorbestimmten Abstand von und parallel zu den Lastwalzenlaufflächen **4**d beabstandet zu sein. Die Walzenstützpfade **7** bilden einen nicht belasteten Bereich der Walzenzirkulationspfade.

[0060] U-förmige Umkehrpfade **8**, welche die Lastwalzenlauffläche **4**d, **4**d mit beiden Enden der entsprechenden Walzenstützpfade **7** verbinden und die Walzen **3** zirkulieren sind in den entsprechenden Hülsenabschnitten **2**b vorgesehen. Ein Umkehrpfad **8** verbindet die obere Lastwalzenlauffläche **4**d mit dem unteren Walzenstützpfad **7**, und der andere Umkehrpfad **8** verbindet die untere Lastwalzenlauffläche **4** mit dem oberen Walzenstützpfad **7**. Somit besteht ein höhengleicher Übergang zwischen einem Paar von Umkehrpfaden **8**. Die Umkehrpfade **8** bilden auch nicht belastete Bereiche der Walzenzirkulationspfade.

[0061] Ringförmige Walzenzirkulationspfade sind durch die Lastwalzenlaufflächen **4**d, einem Paar der Umkehrpfade **8** und die Walzenstützenpfade **7** gebildet. Jeder der Walzenzirkulationspfade ist in einer einzelnen Ebene gebildet, und die Walzen **3** zirkulieren zweidimensional innerhalb jedem der Walzenzirkulationspfade. Eine Ebene, in welcher ein Walzenzirkulationspfad vorhanden ist, kreuzt unter einem rechten Winkel eine andere Ebene, in welcher ein anderer Walzenzirkulationspfad existiert. Hier ist ein Walzenzirkulationspfad innerhalb des anderen Walzenzirkulationspfades vorhanden.

[0062] Wie in **Fig.** 8 dargestellt, weist der bewegliche Block **2** auf ein Stahlblockelement **4**, Kunststoff-Zirkulationspfad-bildende Elemente aus Kunststoff **11**, **12**, **13**, **15**a, **15**b und **20**, die in den Blockhauptkörper **4** aufzunehmen sind, und ein Paar von Seitenabdeckungen **5**, die an den entsprechenden Endflächen des Hauptblockkörpers **4**, der die Zirkulationspfad-bildenden Elemente aus Kunststoff **11**, **12**, **13**, **15**a, **15**b und **20** darin aufgenommen hat, zu befestigen sind. Vorsprünge **4**c, die zu der Geometrie der Rillen **1**a passen, sind den entsprechenden Hülsenabschnitten **4**b des Blockhauptkörpers **4** gebildet. Die zweiten Lastwalzenlaufflächen **4**d, die als Lastwälzelement Laufabschnitte entsprechend zu den Wälzlaufflächen **1**b dienen, sind auf jedem der Vorsprünge **4**c gebildet (siehe **Fig.** 9). Zwei Lastwalzenlaufflächen **4**d sind in den entsprechend Hülsenabschnitten **4**b des Blockhauptkörpers **4** gebildet; namentlich insgesamt vier Lastwalzenlaufflächen. In der vorliegenden Ausführungsform sind die zwei Walzenlaufflächen **1**b und die zwei Lastwalzenlaufflächen **4**d auf beiden Seiten des Blockhauptkörpers **4** gebildet. Die Anzahl der Walzenlaufflächen **2**b und die Anzahl der Lastwalzenlaufflächen **4**d können auf verschiedene Werte in Abhängigkeit vom Typ der Linearbewegungsführungsvorrichtung eingestellt sein.

[0063] Die Zirkulationspfad-bildenden Elemente aus Kunststoff weisen alle Elemente **11**, **12** und **13** auf, die sich entlang seitlicher Kanten der entsprechenden Lastwalzenlaufflächen **4**d erstrecken und das Entfernen der Walzen **3** aus den Lastwalzenlaufflächen **4**d verhindern, wenn der bewegliche Block **2** von der Schiene **1** entfernt wird; Stützpfadsbildungselemente **14** zum Zurückführen der Walzen **3**; und Innenradiusführungsabschnitts-bildende Elemente **15**a und **15**b zum Bilden von Innenradiusführungsabschnitten der Umkehrpfade **8**. Die Halteelemente **11**, **12**, **13**, die Stützpfads-bildenden Elemente **14**, ein Paar der Innenradiusführungsabschnitts-bildenden Elemente **15**a, und ein Paar der Innenradiusführungsabschnitts-bildenden Elemente **15**b sind aus Harz getrennt von dem Blockhauptkörper **4** gebildet. Sie sind in den Hauptkörper **4** eingeschlossen.

[0064] Wie in **Fig.** 9 dargestellt, sind die Halteelemente in erste Halteelemente **11** zum Halten unterer Abschnitte der unteren Walzen **3** und untere Abschnitte der oberen Walzen **3**; und dritte Halteelemente **13** zum Halten oberer Abschnitte der oberen Walzen **3** aufgeteilt. Diese Halteelemente wirken als Flansche zum Führen der Walzen **3** in axialer Richtung.

[0065] Wie in **Fig.** 8 dargestellt, sind die ersten Halteelemente **11** aus langen, dünnen Kunststoffformprodukten gebildet. Mittels des Einschließens der ersten Halteelemente **11** in dem Blockhauptkörper **4** sind Führungsrillen **11**a (siehe **Fig.** 9) gebildet, die als Führungsabschnitte zum Führen eines Verbindungsriemens des Rollenhalters **10** dienen, was später zu beschreiben ist. Als Ergebnis daraus, dass die ersten Halteelemente **11** zwischen dem Paar von Seitenabdeckungen **5** eingelegt sind, sind die ersten Halteelemente **11** an dem beweglichen Block **2** befestigt, während beide Enden gelagert sind.

[0066] Die zweiten Halteelemente **12** sind aus langen, dünnen Kunststoffformprodukten gebildet. Führungsrillen **12**a (siehe **Fig.** 9) sind auf beiden Seiten jedes zweiten Halteelements **12** zum Führen des Verbindungsriemens des Rollenhalters **10** gebildet. Als Ergebnis daraus, dass die zweiten Halteelemente **12** zwischen dem Paar von Seitenabdeckungen **5** eingelegt sind, sind die zweiten Halteelemente **5** an dem beweglichen Block **2** befestigt, während beide Enden gelagert sind.

[0067] Die dritten Halteelemente **13** sind aus langen, dünnen Kunststoffformprodukten gebildet. Mittels Einschließens der dritten Halteelemente **13** in den Blockhauptkörper **4** sind Führungsrillen **13**a (siehe **Fig.** 9) gebildet, die als Führungsabschnitte zum Führen eines Verbindungsriemens des Rollenhalters **10** dienen, was später zu beschreiben ist. Als Ergebnis daraus, dass die dritten Halteelemente **13** zwischen dem Paar von Seitenabdeckungen **5** eingelegt sind; sind die dritten Halteelemente **13** an dem beweglichen Block **2** befestigt, während beide Enden gelagert sind, wie in dem Fall der ersten Halteelemente **11**.

[0068] Jede dieser Stützpfad-bildenden Elemente **14** ist aus halbrohrförmigen Elementen **14**a, **14**b gebildet, die durch Trennen eines Rohres in zwei Teile in der Richtung der Rotationsachse gebildet sind. Jedes der halbrohrförmigen Elemente **14**a, **14**b besitzt eine Rille **20**, die zu der Geometrie der Walzen **3** sich in Längsrichtung erstreckend passt; eine Führungsrille **20**a (siehe **Fig.** 9), die als Führungsabschnitt zum Führen des Verbindungsriemens des Walzenhalters **10** dient; und ein Flansch **19**, der sich in Längsrichtung entlang beiden Seiten der Rille **20** erstreckt. Die Walzenstützpfade **7** sind durch die Stützpfad-bildenden Elemente **14** gebildet.

[0069] Die Innenradiusführungsabschnitt-bildenden Elemente **15**a sind in zwei Teile in Längsrichtung der Schiene **1** geteilt. Mittels Zusammensetzens der zwei Innenradiusführungsabschnitt-bildenden Elemente **15**a wird ein Umkehrpfad der höhengleichen Verbindung gebildet. Weiterhin ist eine Führungsrille, die als Führungsabschnitt zum Führen des Verbindungsriemens des Walzenhalters **10** dient, in dem Umkehrpfad gebildet. Ein Innenradiusführungsabschnitt **21** für einen innenradiusseitigen Walzenzirkulationspfad ist in einem geteilten Element **15**a gebildet, das dem beweglichen Block **2** (d. h. dem inneren) zugewandt ist. Der Innenradiusführungsabschnitt **21** ist in der Form eines im wesentlichen halbkreisförmigen Bogens gebildet. Ein Außenradiusführungsabschnitt **31** für den innenradiusseitigen Walzenzirkulationspfad und ein Innenradiusführungsabschnitt **32** für den außenradiusseitigen Walzenzirkulationspfad sind in einem geteilten Element **15**b, das der Seitenabdeckung **5** (d. h. dem Äußeren) zugewandt ist.

[0070] Der innenradiusseitige Führungsabschnitt **32** und der außenradiusseitige Führungsabschnitt **31** sind in der Form eines im wesentlichen halbkreisförmigen Bogens gebildet.

[0071] Jede der Seitenabdeckungen **5** ist im Querschnittsprofil an den Blockhauptkörper **4** angepasst. Die Seitenabdeckung **5** besitzt einen horizontalen Querschnitt **5**a und ein Paar von Hülsenabschnitten **5**b. Die Außenradiusführungsabschnitte **36** für die außenradiusseitigen Walzenzirkulationspfade sind in den Hülsen **5**b gebildet. Weiterhin sind die Innenradiusführungs-bildenden Elemente **15**a, **15**b, die zusammen kombiniert sind, an die entsprechenden Hülsen **5**d angepasst.

[0072] Wie in **Fig.** 8 dargestellt, sind die Seitenabdeckungen **5** an den entsprechenden längsseitigen Enden des Blockhauptkörpers **4** befestigt. Bolzen sind in Bolzeneinfügelöchern, die in den Seitenabdeckungen **5** gebildet, eingefügt, und die Bolzen sind in Schraubeneingriff mit Schraubenlöchern, die in den Endflächen des Blockhauptkörpers **4** gebildet sind, wodurch die Seitenabdeckungen **5** an den Blockhauptkörper **4** befestigt sind. Daraus ergibt sich, dass die Innenradiusführungsabschnitte **15**a, **15**b an dem Blockhauptkörper **4** befestigt sind. Weiterhin ist eine dekorative Platte **38** an dem äußeren jeder der Seitenabdeckungen **5** befestigt.

[0073] **Fig.** 10A und 10B zeigen die Walzen **3**, die durch die Walzenzirkulationspfade zirkulieren. **Fig.** 10A zeigt die Walzen **3**, die durch den belasteten Bereich rotieren, der zwischen der Walzenlauffläche **1**b der Schiene **1** und dem beweglichen Block **2** definiert ist; und **Fig.** 10B zeigt die Walzen **3**, die sich durch den Stützpfad bewegen, der als nicht belasteter Bereich dient.

[0074] Wie in **Fig.** 10A dargestellt, ist der Walzenzirkulationspfad in dem Lastbereich derart gebildet, um ein rechteckiges Querschnittsprofil anzunehmen, das zu dem Querschnittsprofil der Walze **3** passt. Führungsflansche **41** sind in dem beweglichen Block **2** mittels der Halteelemente **11**, **12** und **13** zum Führen der Endflächen der Walzen **3** gebildet, die in der Richtung der Rotationsachse davon angeordnet sind. Ein Abstand L+ΔL zwischen den Flanschen **41** ist derart eingestellt, um etwas länger zu sein als die Länge L der Walzen **3**, die in der Richtung der Rotationsachse davon derart platziert sind, dass ein Axialspalt ΔL entsteht. Hier ist $\xi = \Delta L/L$ derart eingestellt, um in einem Bereich von beispielsweise 0,02 bis 0,07 zu liegen. Führungsrillen **11**a, **12**a und **13**a sind in den entsprechenden Flanschen **41** zum Führen eines Paars von Verbindungsriemen des Walzenhalters **10** gebildet, was später zu beschreiben ist.

[0075] Wie in **Fig.** 10B dargestellt, ist der Walzenzirkulationspfad in den nicht belasteten Bereich ebenso derart gebildet, um ein rechteckiges Querschnittsprofil anzunehmen, das zu dem Querschnittsprofil der Walze **3** passt. Führungsflansche **43** sind in dem beweglichen Block **2** von den Stützpfad-bildenden Elementen **14** zum Führen der Endflächen der Walzen **3** gebildet, angeordnet in der Richtung einer Rotationsachse davon. Ein Abstand L+ΔL zwischen den Flanschen **43** ist derart eingestellt, um etwas länger zu sein als die Länge L der Walze **3**, die in der Richtung einer Rotationsachse davon derart angeordnet ist, dass dort ein Axialspalt ΔL entsteht. Führungsrillen **20**a zum Führen eines Paares von Verbindungsriemen des Walzenhalters **10**, wie später beschrieben, sind in den entsprechenden Flanschen **43** gebildet. Eine Abmessung zwischen der Innenradiusführungsfläche **51** und der Außenradiusführungsfläche **52** des Walzenzirkulationspfades im nicht belasteten Bereich ist derart eingestellt, um etwas größer zu sein als der Durchmesser der Walze **3**, so dass ein schmaler Spalt entsteht zwischen dem äußeren Umfang der Walze **3** und den Innenradius- und Außenradiusführungsflächen **51**, **52**.

[0076] **Fig.** 11A und 11B zeigen ein Verhältnis des Durchmessers Da der Walze **3** zu der Länge L derselben. **Fig.** 11A zeigt die Walze **3** unter der Annahme L/Da gleich 1,5, und **Fig.** 11B zeigt die Walze **3** unter Annahme L/Da gleich 3. Das Verhältnis des Durchmessers Da der Walze **3** zu der Länge L der Walze **3** ist beliebig eingestellt, um innerhalb dieses Bereichs zu liegen.

[0077] In der vorliegenden Ausführungsform durch Einstellen des Verhältnisses auf näherungsweise 1,5 < L/Da, besitzt die Wälzführungsvorrichtung des Walzentyps eine größere grundlegende statische Belastungsbewertung Co als die Wälzführungsvorrichtung des Kugeltyps in vorstehend beschriebener Weise. Die Angemessenheit der Verwendung der Walze **3**, d. h. eine Wirkung erhöhter Steifigkeit, wird erzielt. Wie in **Fig.** 12A dargestellt, wird der Durchmesser Da der Walze **3** größer als die Länge L derselben in der Richtung einer Rotationsachse mittels Einstellens des Verhältnisses der Walzenlänge zu dem Walzendurchmesser auf L/Da < näherungsweise 3. Wie oben erwähnt kann das Auftreten einer Schrägstellung und Ausfall verhindert werden, ohne Anwendung einer strengen Abmessungskontrolle des axialen Spalts ΔL. Wie in **Fig.** 12B dargestellt, falls das Verhältnis auf L/Da > 3 eingestellt ist, nehmen die Walzen **3** die Form einer Nadel an. Somit wird ein Schrägstellungswinkel α unvermeidlich ansteigen, sofern nicht die Abmessungen des Axialspalts ΔL streng kontrolliert werden.

[0078] **Fig.** 13A bis 13C zeigen ein Walzenverbindungselement, das die Walzen **3** darin aufgenommen besitzt. **Fig.** 13A ist eine Draufsicht des Walzenverbindungselements. **Fig.** 13B ist eine Seitenansicht des Walzenverbindungselements, und **Fig.** 13C ist eine Frontansicht desselben. Die Walzen **3** sind miteinander verbunden in der Form einer Kette mittels der Walzenhalter **10**. Ein Walzenverbindungselement ist in jedem der vier Walzenzirkulationspfade aufgenommen. Der Walzenhalter **10** ist integral durch die Abstandhalter **46** und die Verbindungsriemen **47** unter Verwendung der Verbindungsstücke **48** gebildet. Somit bildet der gesamte Walzenhalter **10** einen Streifen, der Erden besitzt. Um das Befestigen des Rollenhalters **10** an dem beweglichen Block **2** zu erleichtern sind vordere Enden **10**a des Rollenhalters **10** abgerundet.

[0079] Die Abstandhalter **46** sind in der Form eines im wesentlichen rechtwinkligen Würfels gebildet. Mit Vertiefungen versehene Oberflächen **59**, die zu der Geometrie des äußeren Umfangs der benachbarten Walzen **3** passen, sind in jedem der Abstandhalter **46** gebildet. Die mit Vertiefungen versehene Oberflächen **49** kommen in gleitbaren Kontakt mit den äußeren Umfangsflächen der Walzen **3**. Die Breite des Abstandshalters **46** ist etwas kürzer ausgeführt als die Länge der Walze **3** in der Richtung einer Rotationsachse davon.

[0080] Das Paar von Verbindungsriemen **47** ist mit Seitenflächen **50** der entsprechenden Abstandhalter **46** in der Richtung der Rotationsachse der Walzen **3** verbunden. Die Verbindungsriemen **47** ragen seitlich von den Endflächen der Walzen **3** in Bezug auf die Richtung der Rotationsachsen hervor. Die Verbindungsriemen **47** sind innerhalb einer Ebene gelegen, welche die Rotationsachsen der Walzen **3** einschließt. Darüber hinaus sind die Verbindungsriemen **47** dünn ausgeführt, um flexibel in Übereinstimmung mit dem Walzenzirkulationspfad zu sein.

[0081] Wie in **Fig.** 13 dargestellt, stimmt die Breite W2 des Verbindungsstücks **48** in der Längsrichtung des Verbindungsriemens **47** mit dem geringsten Abstand zwischen den mit Vertiefungen versehenen Oberflächen **49** überein. Die Breite W3 des Verbindungsstücks **48** in der Richtung einer Rotationsachse der Walze **3** ist auf einen solchen Wert eingestellt, dass die Abstandhalter **46** sich gegenüber den Verbindungsriemen **47** neigen können. Wie in **Fig.** 13C dargestellt, ist eine Verstärkungsrippe **53** in jedem der Verbindungsstücke **48** gebildet. Die Verstärkungsrippen **53** verhindern, dass sich die Verbindungsriemen **47** in einer Richtung **2** in Bezug auf die Abstandshalter **46** senkrecht zu der Ebene bewegen, welche die Rotationsachse der Walzen **3** einschließt. Umgekehrt verhindern die Verstärkungsrippen **53**, dass die Abstandhalter **46** und, durch Ausdehnung, die Walzen **3** sich in Richtung (2) senkrecht zu der Ebene, welche die Rotationsachsen der Walzen **3** einschließt, und in Richtung (1) gegenüber den Verbindungsriemen **47** bewegen. Die Verbindungsriemen **47** sind durch die Führungsrille derart geführt, um sich entlang eines vorbestimmten Pfades zu bewegen. Somit können die Walzen **3** entlang eines vorbestimmten Pfades ohne Ausfall bewegt werden, mittels Verhinderns, dass die Walzen **3** sich in einer Richtung (2) gegenüber den Verbindungsriemen **47** bewegen.

[0082] Da der Walzenhalter **10** die Walzen **3** in eine vorbestimmte Position ausrichtet kann das Auftreten einer Schrägstellung der Walzen **3** verhindert werden. Selbst wenn eine Schrägstellung entstanden ist kann die Schrägstellung der Walzen **3** derart korrigiert werden, dass die Walzen **3** erneut vorbestimmte Rotationsachsen einnehmen, mittels der elastischen Rückstellkraft des Paares von Verbindungsriemen **47**. Somit besitzt der Walzenhalter **10** die Wirkung des Ausrichtens der Walzen **3** in eine vorbestimmte Position und die Wirkung des Verhinderns der Akkumulation einer Schrägstellung der Walzen **3**. Weiterhin kann der Schrägstellungswinkel vermindert werden mittels des Einstellens des Verhältnisses des Walzendurchmessers zur Walzenlänge auf L/Da < näherungsweise 3. Dementsprechend in Zusammenwirken der Wirkungen des Walzenhalters **10**, der die Walzen **3** in eine vorbestimmte Position ausrichtet und die Akkumulation der Schrägstellung verhindert, kann eine Schrägstellung der Rollen ohne Ausfall verhindert werden. Da der Rollenhalter **10** durch die Führungsrillen **11**a, **12**a, **13**a und **20**a derart geführt ist, um einen vorbestimmten Pfad in dem Walzenzirkulationspfad aufrecht zu erhalten. Somit halten die Walzen **3**, die durch den Walzenhalter **10** gehalten sind, auch einen vorbestimmten Pfad ein, und die Walzen **3** können geeigneter ausgerichtet werden.

[0083] Obwohl die vorstehende Ausführungsform die Wälzführungsvorrichtung als Linearbewegungswälzführungsvorrichtung zum Führen einer Linearbewegung angewendet hat, ist die Erfindung nicht auf Linearbewegung begrenzt. Ebenso kann eine Kurvenbewegungsführungsvorrichtung zum Führen einer gekrümmten Bewegung angewendet werden. Alternativ kann ebenso eine sogenannte Walzentyp-Wälzführungsvorrichtung angewendet werden, die nicht mit einem Halter ausgestattet ist.

[0084] Wie beschrieben worden ist, wird mittels des Einstellens eines Verhältnisses der Walzenlänge zum Walzendurchmesser auf einen Wert von näherungsweise 1,5 < L/Da die grundlegende statische Belastungsbewertung Co der Wälzführungsvorrichtung des Walzentyps größer als diejenige der Wälzführungsvorrichtung des Kugeltyps, wenn die Teile der Vorrichtungen vom selben Modell sind. Somit wird die Eignung der Verwendung von Walzen, d. h. eine Erhöhung der Steifigkeit der Walzen, erzielt. Mittels Einstellens des Verhältnisses auf einen Wert von L/Da < näherungsweise 3, kann das Auftreten einer Schrägstellung ohne Ausfall verhindert werden, ohne Anwenden einer strengen Abmessungskontrolle des Axialspalts ΔL. Somit kann das Auftreten einer Schrägstellung von Rollen und eine Erhöhung der Steifigkeit ohne Ausfall erzielt werden.

[0085] Der Walzenhalter richtet die Walzen in eine vorbestimmte Position aus und verhindert das Auftreten einer Schrägstellung der Walzen. Selbst wenn eine Schrägstellung aufgetreten ist, kann die Schrägstellung der Walzen derart korrigiert werden, dass die Walzen wieder ihre vorbestimmten Rotationsachsen einnehmen, mittels der elastischen Rückstellkraft der Verbindungsabschnitte. Somit besitzt der Walzenhalter die Wirkung des Ausrichtens der Walzen in eine vorbestimmte Position und die Wirkung des Verhinderns der Akkumulation der Schrägstellung der Walzen. Weiterhin kann ein Schrägstellungswinkel vermindert werden mittels des Einstellens des Verhältnisses des Walzendurchmessers zur Walzenlänge auf L/Da < näherungsweise 3. Dementsprechend kann in Zusammenwirkung mit den dargelegten Wirkungen des Walzenhalters eine Schrägstellung der Walzen ohne Ausfall verhindert werden.

Patentansprüche

1. Wälzführungsvorrichtung, die aufweist:
eine Laufringwelle, die Walzenlaufringflächen besitzt,
ein bewegliches Element, das Walzenzirkulationspfade besitzt, die Lastwalzenlaufringflächen entsprechend den jeweiligen Walzenlaufringflächen einschließen und an der Laufringwelle in relativ beweglicher Weise befestigt sind; und
eine Vielzahl von Walzen, die in den Walzenzirkulationspfaden angeordnet und aufgenommen sind und in Assoziation mit einer Bewegung der beweglichen Elemente gegenüber der Laufringwelle zirkulieren,
worin die Walzen derart gebildet sind, um ein Verhältnis von näherungsweise 1,5 < L/Da < näherungsweise 3 zu erfüllen, wobei der Durchmesser der Walze als Da definiert ist und die Länge der Walze entlang einer Richtung einer Rotationsachse als L angenommen ist.

2. Wälzführungsvorrichtung nach Anspruch 1, worin die Vielzahl von Walzen derart angeordnet ist, dass die Rotationsachsen der Walzen parallel zueinander gebracht sind; die Wälzführungsvorrichtung besitzt einen Walzenhalter zum rotierbaren und gleitbaren Halten der Vielzahl von Walzen; und der Walzenhalter besitzt eine Vielzahl von Abstandhaltern, die jeweils zwischen den Walzen eingelegt sind, und flexible Verbindungsabschnitte zum gegenseitigen Verbinden der Abstandhalter.

3. Wälzführungsvorrichtung nach Anspruch 2, worin eine mit Vertiefungen versehene Oberfläche, die zu der Geometrie der äußeren Oberfläche jeder der Walzen passt, auf beiden Seiten der Abstandhalter gebildet ist.

4. Wälzführungsvorrichtung nach Anspruch 2, worin die Verbindungsabschnitte seitlich von den Endflächen der Walzen in Bezug auf die Richtung der Rotationsachsen herausragen.

5. Wälzführungsvorrichtung nach Anspruch 2, worin Führungsabschnitte entlang der Walzenzirkulationspfade des beweglichen Elements gebildet sind.

6. Walzenverbindungselement, das aufweist:
einen Walzenhalter, der einschließt:
eine Vielzahl von Walzen, die derart angeordnet sind, dass die Rotationsachsen der Walzen parallel zueinander gebracht sind; und
einen Walzenhalter, der eine Vielzahl von Abstandhaltern besitzt, die jeweils zwischen den Walzen eingelegt sind, und flexible Verbindungsabschnitte zum gegenseitigen Verbinden der Abstandhalter, worin die Walzen derart gebildet sind, um eine Beziehung von näherungsweise 1,5 < L/Da < näherungsweise 3 zu erfüllen, wobei der Durchmesser der Walzen als Da definiert ist und die Länge der Walzen in einer Richtung der Rotationsachse davon als L angenommen ist.

7. Walzenverbindungselement nach Anspruch 6, worin eine mit Vertiefungen versehene Oberfläche, die zu der Geometrie der äußeren Oberfläche jeder der Walzen passt, auf beiden Seiten der Abstandhalter gebildet ist.

8. Walzenverbindungselement nach Anspruch 6, worin die Verbindungsabschnitte seitlich von den Endflächen der Walzen in Bezug auf die Richtung der Rotationsachsen herausragen.

Die folgenden Angaben sind den vom Anmelder eingereichten Unterlagen entnommen

(54) Führungsvorrichtung

(57) Eine Führungsvorrichtung umfasst eine Spurschiene, die Laufringoberflächen für Wälzkörper in Längsrichtung gebildet hat, ein Gleitstück, das eine Lastlaufringoberfläche gegenüber der Laufringoberfläche hat und einen Rückkehrweg für Wälzkörper, der parallel zu der Lastlaufringoberfläche angebracht ist, und das ein Paar von Richtungsumkehrwegen hat, die einen endlosen Umkehrweg für die Wälzkörper durch Verbinden der Lastlaufringoberfläche mit beiden Enden des Rückkehrwegs vervollständigen, und das an der Spurschiene angebracht ist, so dass deren Relativbewegung ermöglicht wird, und mehrere Wälzelemente, die für Last in einer Position zwischen einer Lastlaufringoberfläche des Gleitstücks und der Laufringoberfläche der Spurschiene empfänglich sind und in dem endlosen Umlaufweg umlaufen. Eine Stufe, bei der die Lastlaufringoberfläche niedriger als eine Seitenwandoberfläche an einem inneren Durchmesser des Richtungsumkehrwegs wird, ist an einem Ort gebildet, an dem der Richtungsumkehrweg mit der Lastlaufringoberfläche verbunden ist.

DE 101 56 339 A 1

Beschreibung

HINTERGRUND DER ERFINDUNG

1. Gebiet der Erfindung

[0001] Die vorliegende Erfindung bezieht sich auf eine Führungsvorrichtung, die in einem linearen Führungsabschnitt von beispielsweise einer Werkzeugmaschine oder einem ähnlichen Werkzeug verwendet wird, um ein bewegbares Element, wie einen Tisch, über einen stationären Abschnitt, wie ein Bett, zu führen, und bei der ein Gleitstück, das mit mehreren Wälzelementen ausgerüstet ist, die endlos umlaufen, frei nach vorne und hinten entlang einer Führungsschiene läuft.

[0002] Insbesondere bezieht sich die vorliegende Erfindung auf eine Verbesserung hinsichtlich der Hochgeschwindigkeitsbewegung eines Gleitstücks auf der Laufringschiene.

2. Beschreibung des Stands der Technik

[0003] Als Führungsvorrichtung dieser Art ist bislang eine Führungsvorrichtung bekannt, die eine auf einem stationären Abschnitt, wie einem Bett, angebrachte Spurschiene umfasst und eine Laufringoberfläche für Wälzelemente, wie Laufrollen, hat, die darauf geformt ist; und ein Gleitstück, das an der Spurschiene durch eine Vielzahl von Wälzelementen angebracht ist und entlang der Spurschiene läuft, wobei es ein bewegliches Element, wie einen Tisch, stützt.

[0004] Das Gleitstück hat eine Lastlaufringoberfläche, die gegenüber einer Laufringoberfläche einer Spurschiene in bezug auf Wälzelemente ist, und einen Rückkehrweg, der parallel zu der Lastlaufringoberfläche angebracht ist. Ferner umfasst das Gleitstück einen Gleitblock, der entlang der Spurschiene in Verbindung mit dem Abwälzen der Wälzelemente bewegbar ist, und ein Paar von Endkappen. Die Endkappen sind an jeweiligen Endflächen des Gleitblocks befestigt und haben einen U-förmigen Kehrenweg (genannt ein U-Kehrenweg). Der U-Kehrenweg führt Wälzelemente in Richtung auf den Rückkehrweg, die an einer Position zwischen der Lastlaufringoberfläche des Gleitblocks und der Lastlaufringoberfläche der Spurschiene angelangt sind. Die Endkappen sind an den jeweiligen Endflächen des Gleitblocks befestigt, als Folge dessen die Lastlaufringoberfläche mit dem Ende des Rückkehrwegs durch den U-förmigen Weg verbunden ist. Somit entsteht ein endloser Umlaufweg innerhalb des Gleitstücks.

[0005] Die Wälzkörper, die um den endlosen Umlaufweg des Gleitstücks umlaufen, rollen durch einen Ort zwischen der Lastlaufringoberfläche des Gleitblocks und dem Laufring der Spurschiene. Insbesondere rollen die Wälzelemente durch ein Lastgebiet, wobei sie die Last aufnehmen, die auf den Gleitblock ausgeübt wird. In einem Nichtlastgebiet wird die Last auf die Wälzelemente gelöst und sie rollen in einem Nichtlastzustand, in dem keine Last auf die Wälzkörper aufgebracht wird. **Fig.** 7 ist eine vergrößerte Querschnittansicht, die eine Verbindung zwischen dem Nichtlastgebiet und dem Lastgebiet zeigt. Insbesondere zeigt die Zeichnung, dass die Wälzkörper **101**, die durch einen U-förmigen Weg **100** gerollt sind, ohne eine Last aufzunehmen, in eine Position zwischen einer Laufringoberfläche **103** einer Spurschiene **102** und einem Lastlaufring **105** eines Gleitblocks **104** gelangen. Die Lastlaufringoberfläche **105** des Gleitblocks **104** und die Wälzkörper **100**, wie Kugeln oder Zylinder, sind aus Stahl gefertigt, aber keine vollständig steifen Körper und habe eine leichte Elastizität. In dem Lastgebiet erfahren die Lastlaufringoberfläche **105** und die Wälzkörper **101** eine leichte elastische Deformation aufgrund von Last, und in dem Nichtlastgebiet nehmen die Wälzkörper ihre ursprünglichen Gestalten wieder ein, wenn die Last entfernt wird. Aus diesem Grund sind der innere Durchmesser des Rückkehrwegs und derjenige des U-Kehrenwegs **100**, die das Nichtlastgebiet bilden, größer als der Durchmesser des Wälzkörpers **101**. Ein Intervall zwischen der Lastlaufringoberfläche **105** des Gleitblocks **104** in dem Lastgebiet und der Laufringoberfläche **103** der Spurschiene **102** ist jedoch kleiner als der Durchmesser des Wälzkörpers **101**. Wenn somit die Wälzkörper **101**, die durch das Nichtlastgebiet gerollt sind, abrupt in das Lastgebiet gelangen, werden die Wälzkörper **101** einer abrupten Kompression am Eingang des Lastgebiets ausgesetzt. Als Folge entsteht ein höherer Widerstand bei der Zirkulation der Wälzkörper **101** und das Geräusch, das mit der Zirkulation der Wälzkörper **101** verbunden ist, wird stärker. Aus diesen Gründen wurde, um gleichmäßig und elastisch die Wälzkörper **101** zu deformieren, die in das Lastgebiet aus dem Nichtlastgebiet gelangen, bislang jedes Ende in Längsrichtung der Lastlaufringoberfläche **105** keilförmig gestaltet. Jedes Ende des Lastgebiets ist leicht verbreitert, in der Form eines Glockenbodens, in Richtung auf das Nichtlastgebiet. Durch solche ein Verbreiterung des Lastgebiets rollen die Wälzkörper **101**, die in das Lastgebiet aus den Nichtlastgebiet gerollt sind, in die Tiefe des Lastgebiets, so dass der Zirkulationswiderstand und das Geräusch der Wälzkörper **101** verringert wird.

[0006] Wie oben beschrieben, wird der U-Kehrenweg **100**, der das Nichtlastgebiet bildet, durch die Endkappe **107** definiert, die sich von dem Gleitblock **104** unterscheidet, der die Lastlaufringoberfläche **105** darauf gebildet hat. Um einen glatten Übergang der Wälzkörper **101** zwischen dem Nichtlastgebiet und dem Lastgebiet zu bewirken, muss die Endkappe **107** genau in bezug auf den Gleitblock **104** positioniert werden. Im Stand der Technik wurde ein Versuch unternommen, die positionale Genauigkeit beim Anbringen der Endkappe **107** an dem Gleitblock **104** zu verbessern, indem ein Vorsprung, der von der Endkappe **107** vorsteht, in ein ausgespartes Loch eingepasst wird, das in der Endfläche des Gleitblocks **104** geformt ist, wodurch der Rand der ballig gedrehten Lastlaufringoberfläche **105** mit einer Seitenwandoberfläche **106** am inneren Umriss des U-Kehrenwegs **100** vollständig in Übereinstimmung gebracht wird.

[0007] Selbst wenn die positionale Genauigkeit beim Montieren der Endkappe **107** relativ zu dem Gleitblock **104** verbessert worden ist, wird die Seitenwandoberfläche **106** am Innendurchmesser des U-Kehrenwegs **100** niedriger als der Rand der Lastlaufringoberfläche **105** durch das Verhältnis zwischen der Genauigkeit beim Ausbilden der Lastlaufringoberfläche **105** und der Genauigkeit beim Ausbilden der Kunststoffendkappe **107**, wie es durch gestrichelte Linien angegeben ist, die in **Fig.** 7 gezeigt sind. Möglicherweise kann ein Fall auftreten, in dem der Rand der Lastlaufringoberfläche **105** leicht an einer Verbindung zwischen der Lastlaufringoberfläche **105** und dem U-Kehrenweg **100** vorsteht. Auf diese Weise kollidieren die Wälzkörper **101** mit dem Rand der so vorspringenden Lastlaufringoberfläche **105**, wenn die Wälzkörper **101** in das Lastgebiet aus dem U-Kehrenweg **100** eindringen. Solch eine Kollision bildet kein ernsthaftes Problem, wenn das Gleitstück entlang der Spurschiene mit einer geringen Geschwindigkeit läuft; die Kollision bildet jedoch ein bemerkenswertes Problem, wenn die Geschwindigkeit erhöht werden muss, mit der das Gleitstück entlang der Spurschiene laufen soll. Wenn die Geschwindigkeit, mit der das Gleitstück entlang der Spurschiene läuft, erhöht wird, kommen somit innerhalb einer vorgegebenen Zeitdauer eine größere Anzahl von Kugeln zur Kollision mit der Lastlaufringoberfläche. Als Folge wird der Widerstand, der hinsichtlich der Zirkulation der Wälzkörper auferlegt wird, oder die Geräuschbildung merklich. Da ferner die Aufprallenergie proportional zum Quadrat der Geschwindigkeit ist, wird der Rand der vorspringenden Lastlaufringoberfläche hinsichtlich einer Beschädigung anfällig.

[0008] Ein halbkreisförmiger Führungsabschnitt, der am Innendurchmesser des U-Kehrenwegs **100** positioniert ist, ist bislang an einer Endkappe oder einem Gleitblock angebracht worden. Um jedoch die Genauigkeit beim Ausbilden eines endlosen Umlaufwegs zu erhöhen, wurde kürzlich das direkte Ausbilden des halbkreisförmigen Führungsabschnitts an der Endfläche des Gleitblocks durch Spritzgießen von Kunststoff (Kunstharz) durchgeführt (wie es in der japanischen offengelegten Patentanmeldung Nr. 317762/1995 beschrieben ist). Selbst in diesem Fall ist es schwierig, den Rand der Lastlaufringoberfläche mit der inneren Seitenoberfläche des U-Kehrenwegs in Übereinstimmung zu bringen, der einen halbkreisförmigen Führungsabschnitt hat, ohne dass sich eine Stufe ausbildet. Die Hochgeschwindigkeitszirkulation von Wälzkörpern ist mit den vorher beschriebenen Problemen verbunden.

ZUSAMMENFASSUNG DER ERFINDUNG

[0009] Die vorliegende Erfindung wurde im Hinblick auf diese Nachteile getätigt und strebt danach, eine lineare Führungsvorrichtung vorzusehen, die das Auftreten von Kollisionen von Wälzkörpern vermeidet, die andernfalls auftreten würde, wenn die Wälzkörper in ein Lastgebiet aus einem Nichtlastgebiet rollen, so dass ein Gleitwiderstand und Geräusche verringert werden, die andernfalls auftreten würden, wenn sich ein Gleitstück mit hoher Geschwindigkeit relativ zu einer Spurschiene bewegt.

[0010] Um die Aufgabe zu erzielen, stimmt idealer Weise die Lastlaufringoberfläche vollständig mit der Seitenwandoberfläche überein und geht kontinuierlich in sie am inneren Durchmesser des U-Kehrenwegs über, wenn die lineare Führungsvorrichtung zusammengefügt wird. Vorgegebene Toleranzen sind jedoch im Rahmen der Fertigungsgenauigkeit einzelner Komponenten oder einer Positioniergenauigkeit vorhanden. Um eine ideale Übereinstimmung zwischen der Lastlaufringoberfläche und der Seitenwandoberfläche zu erzielen, müssen ein Gleitstückhauptkörper und Endkappen mit einem beträchtlich hohen Maß an Genauigkeit gefertigt werden und die so hergestellten Komponenten müssen mit einem beträchtlich hohen Maß an Präzision zusammengefügt werden. Daher ist es äußerst schwierig, eine solche hochgenaue Herstellung und ein solches Zusammenfügen von Teilen zu erreichen.

[0011] Bei der linearen Führungsvorrichtung gemäß der vorliegenden Erfindung sind die Seitenwandoberfläche am inneren Durchmesser des U-Kehrenwegs und die Lastlaufringoberfläche nicht mit der Absicht gebildet, dass sie an dem Ort kontinuierlich werden, an dem der U-Kehrenweg mit der Lastlaufringoberfläche verbunden ist; stattdessen ist es beabsichtigt, einen gestuften Abschnitt zu bilden, so dass der Rand eines Eingangs der Lastlaufringoberfläche niedriger als die Seitenwandoberfläche wird.

[0012] Durch solche technischen Einrichtungen ist der Längsrand der Lastlaufringoberfläche im Vergleich zur Seitenwandoberfläche am inneren Durchmesser des U-Kehrenwegs vertieft. Damit kollidieren die Wälzkörper, die ein Lastgebiet aus dem U-Kehrenweg betreten möchten, nicht mit dem Rand der Lastlaufringoberfläche und die Wälzkörper können glatt an das Lastgebiet aus dem Nichtlastgebiet abgegeben werden. Ferner hat der U-Kehrenweg ursprünglich einen inneren Durchmesser der größer als der Durchmesser der Wälzkörper ist. Selbst wenn die Seitenwandoberfläche am inneren Radius des U-Kehrenwegs über den Rand des Eingangs der Lastlaufringoberfläche vorsteht, werden somit die Wälzkörper, die in den U-Kehrenweg aus dem Lastgebiet eindringen wollen, nicht durch einen Winkel der Seitenwandoberfläche gebremst. Somit können die Wälzkörper gleichmäßig an das Nichtlastgebiet aus dem Lastgebiet abgegeben werden.

[0013] Der gestufte Abschnitt hat eine Größe von etwa 5% des Durchmessers des Wälzkörpers. Der gestufte Abschnitt mit solch einer Größe kann direkt durch Justieren einer Toleranz ausgebildet werden, die mit dem Fertigen der Lastlaufringoberfläche oder der Endkappe verbunden ist. Ferner ist ein erlaubbarer Bereich für die Größe des gestuften Abschnitts verfügbar. Das Fertigen des gestuften Abschnitts ist somit beträchtlich einfacher als das Erreichen einer vollständigen Übereinstimmung zwischen der Seitenwandoberfläche und der Lastlaufringoberfläche.

[0014] Selbst wenn es unmöglich ist, eine Übereinstimmung zwischen der Lastlaufringoberfläche und der Seitenwandoberfläche am inneren Durchmesser des U-Kehrenwegs zu erreichen, indem lediglich die Genauigkeit beim Fertigen der Komponenten oder lediglich das Zusammenfügen von genauen Komponenten festgelegt wird, kann das Erreichen einer Übereinstimmung zwischen der Lastlaufringoberfläche und der Seitenwandoberfläche durch Herstellen der linearen Führungsvorrichtung nach dem Zusammenfügen implementiert werden. Insbesondere wird durch gleichzeitiges Schleifen der Lastlaufringoberfläche und der Seitenwandoberfläche, die einander benachbart sind, ein Vorstehen des Rands des Eingangs der Lastlaufringoberfläche relativ zur Seitenwandoberfläche vermieden, wodurch die Oberflächen so endbearbeitet werden, dass sie ohne Stufe kontinuierlich werden. Damit kann eine ideale Kontinuität zwischen dem Lastgebiet und dem Nichtlastgebiet sichergestellt werden, wobei dies nur wenig Arbeit umfasst, so dass eine gleichmäßige Zirkulation der Wälzkörper erreicht wird.

[0015] Die vorliegende Erfindung kann auf einen endlosen Umlaufweg einer Kugelkeilwelle angewendet werden, die aus einer Keilwelle und einem Mutterelement besteht, das entlang der Welle läuft, ebenso wie auf einen endlosen Kugelumlaufweg einer linearen Führungsvorrichtung, die aus einer Spurschiene und einem Gleitstück besteht.

DETAILLIERTE BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSFORMEN

[0023] Es wird nun eine Beschreibung von bevorzugten Ausführungsformen der Erfindung unter Verweis auf die beigefügten Zeichnungen gegeben.

[0024] Eine lineare Führungsvorrichtung gemäß der vorliegenden Erfindung wird im einzelnen untenstehend unter Verweis auf die beigefügten Zeichnungen beschrieben.

[0025] **Fig.** 1 ist eine perspektivische Ausschnittsansicht, die ein Beispiel einer linearen Führungsvorrichtung zeigt, auf die die vorliegende Erfindung angewendet wird. Die lineare Führungsvorrichtung umfasst eine Spurschiene **1**, die einen Kugellaufring **11** in einer Längsrichtung von ihr gebildet hat; ein Gleitstück **2**, das in Eingriff mit der Spurschiene **1** über eine Vielzahl von Kugeln **3** ist, die als Wälzkörper dienen; und ein Dichtelement **5**, das an einer Endfläche an beiden Enden des Gleitstücks **2** in dessen Bewegungsrichtung angebracht ist und das in direktem Kontakt mit der oberen und Seitenoberfläche der Spurschiene **1** gebracht wird.

[0026] Wie es in **Fig.** 2 gezeigt ist, ist die Spurschiene **1** so konstruiert, dass sie ein im wesentlichen rechteckiges Querschnittsprofil einnimmt, wenn man einen Querschnitt entlang der Richtung senkrecht zur Längsrichtung der Schiene **1** betrachtet. Ein Montageloch **10** zum Einführen eines Verankerungsbolzens ist unter geeigneten Intervallen in der Längsrichtung so geformt, dass es durch die Spurschiene **1** durchdringt. Zwei Kugellaufringnuten **11** sind in einer oberen Oberfläche der Spurschiene **1** so geformt, dass die Montagelöcher **10** zwischen die Kugellaufringnuten **11** zwischengeschaltet sind. Ferner ist eine Kugellaufringnut **11** auf jeder Seitenoberfläche **11** der Spurschiene **1** geformt. Jede der vier Kugellaufringnuten ist in der Gestalt eines tiefen Schlitzes so geformt, der eine Krümmung einnimmt, die etwas größer ist als diejenige einer kugelförmigen Oberfläche der Kugel **3**.

[0027] Das Gleitstück **2** umfasst einen metallischen Gleitblock **21**, der mit einer Montageoberfläche **20** ausgebildet ist, die zum Montieren eines verschiebbaren Elements (nicht gezeigt), wie eines Tischs, verwendet wird, und mit einem Paar von Kunststoffendkappen **22, 22**, die an beiden Endflächen des Gleitblocks **21** befestigt sind. Eine Vertiefung ist in der unteren Oberfläche des Gleitstücks **2** so geformt, dass ein oberer Teil der Spurschiene **1** in die Vertiefung mit Spiel passt. Somit ist das Gleitstück **2** so konstruiert, dass es ein im wesentlichen sattelartiges Querschnittsprofil hat.

[0028] Der Gleitblock **21** hat einen Basisabschnitt **21**a mit der darauf gebildeten Montageoberfläche **20**, und ein Paar von Einfassungen **21**b, **21**b, die sich nach unten von den jeweiligen Seiten des Basisabschnitts **21**a erstreckt. Somit ist der Gleitblock **21** so konstruiert, dass er ein im wesentlichen sattelartiges Querschnittsprofil einnimmt. Mehrere Gewindelöcher **20**a zur Verwendung zum Sichern eines bewegbaren Elements mit Bolzen sind in der Montageoberfläche **20** geformt. Zwei Lastlaufringnuten **23** sind in der unteren Oberfläche des Basisabschnitts **21**a geformt, und eine Lastlaufringnut **23** ist in einer inneren Seitenoberfläche jeder der Einfassungen **21**b geformt. Somit sind eine Gesamtzahl von vier Lastlaufringnuten **23** so gebildet, dass sie entsprechenden Kugellaufringnuten **11** gegenüber sind, die in der Spurschiene **1** geformt sind. Die Kugeln **3** laufen unter Last an einem Ort, der zwischen der Lastlaufringnut **23** und der Kugellaufringnut **11** der Spurschiene **1** definiert wird; insbesondere in einem Lastgebiet. Somit läuft das Gleitstück **2** über die Spurschiene **1**.

[0029] Zwei Kugelrückkehrwege **24** sind in dem Basisabschnitt **21**a des Gleitblocks **21** durch Bohren gebildet, und ein Kugelrückkehrweg **24** ist in jeder der Einfassungen **21**b durch Bohren geformt. Die Kugelrückkehrwege **24** sind parallel zu jeweiligen Lastlaufringnuten **23** angebracht. **Fig.** 3 ist eine Querschnittsansicht, die einen endlosen Kugellaufweg zeigt, der in dem Gleitstück **2** geformt ist. Jeder der Kugelrückkehrwege **24** steht mit einer entsprechenden Lastlaufringnut **23** durch zwei im wesentlichen U-förmige Richtungsumkehrwege **25** (einfach als "U-Kehrenwege" bezeichnet) in Verbindung, die durch die jeweiligen Endkappen **22** definiert werden. Insbesondere führt ein U-Kehrenweg **25** die Kugeln **3** nach oben, die das Rollen durch die Lastlaufringnut **23** des Gleitblocks **21** beendet haben, und liefert die Kugeln **3** an den Kugelrückkehrweg **23**, und der andere U-Kehrenweg **25** liefert die Kugeln **3** aus dem Kugelrückkehrweg **24** zur Lastlaufringnut **23**. Durch Befestigen der Endkappen **23** an dem Gleitblock **21** durch nicht dargestellte Montagebolzen wird ein endloser Umlaufweg für die Kugeln **3** in dem Gleitstück **2** gebildet.

[0030] Wie es in **Fig.** 3 gezeigt ist, ist eine Endfläche auf beiden Seiten des Gleitblocks **21** in der Bewegungsrichtung davon mit einem Kappenbefestigungsabschnitt **40** bedeckt, der zum Verwenden der Endkappe **22** verwendet wird. Ein gestufter Positionierabschnitt **41** zum Aufpassen einer inneren Seitenoberfläche der Endkappe **22** ist in dem Kappenbefestigungsabschnitt **40** geformt. Wenn die Endkappe **22** an dem Gleitblock **21** befestigt wird, positioniert der gestufte Positionierabschnitt **41** die Endkappe **22** genau. Der Kappenbefestigungsabschnitt **40** ist integral mit dem Gleitblock **21** durch ein sogenanntes Einsatzgussverfahren geformt, bei dem geschmolzenes Harz durch Einspritzen in eine Form gegossen wird, die den Gleitblock **21** darin vorgesehen hat. Es kann ein Fall auftreten, in dem der Kappenbefestigungsabschnitt **40** durch Druckgießen von Leichtmetall, wie Aluminium, anstatt von Kunststoff gebildet wird. Das Gießverfahren ist nicht auf das Einsatzgießen beschränkt; der Gleitblock **21** und der Kappenbefestigungsabschnitt **40** können getrennt gebildet werden und später zusammengefügt werden.

[0031] Ein halbkreisförmiger Führungsabschnitt **42** – der eine Seitenwandoberfläche am inneren Durchmesser des U-Kehrenwegs bildet – steht von dem Kappenbefestigungsabschnitt **40** vor. Der Führungsabschnitt **42** bildet den U-Kehrenweg **25** in Verbindung mit der Endkappe **22**. Eine halbkreisförmige Führungsnut **43** ist in der Endkappe **22** geformt und bildet eine Seitenwandoberfläche am äußeren Durchmesser des U-Kehrenwegs **25**. Wenn die Endkappe **22** an dem Kappenbefestigungsabschnitt **40** befestigt ist, ist der Führungsabschnitt **42** des Kappenbefestigungsabschnitts **40** an der Führungsnut **43** der Endkappe **22** befestigt, so dass dadurch der U-Kehrenweg **25** gebildet wird.

[0032] Die Kappenmontageabschnitte **40**, die an beiden Endflächen des Gleitblocks **21** angebracht sind, werden miteinander durch den Kugelrückkehrweg **24** verbunden. Insbesondere ist der Kugelrückkehrweg **24** durch Beschichten der inneren Umfangsoberfläche des Durchgangslochs **44**, das in dem Gleitblock **21** gebildet ist, mit einem röhrenartigen Körper **45** aus Kunststoff gebildet. Solch ein röhrenartiger Körper **45** verbindet das Paar von Kappenbefestigungsabschnitten **40, 40**, die die Endflächen des Gleitblocks **21** bedecken. Der röhrenartige Körper **45** wird durch Einsatzgießen gleichzeitig mit dem Ausbilden des Kappenbefestigungsabschnitts **40** geformt, wodurch die inneren Umfangsoberfläche des Gleitblocks **21** beschichtet wird. Entsprechend sind die Kappenbefestigungsabschnitte **40**, die an den Endflächen des Gleitblocks **21** geformt sind, miteinander integral durch den röhrenartigen Körper **45**, der durch den Gleitblock **21** durchdringt. Die Kappenbefestigungsabschnitte **40** sind fest an dem metallischen Gleitblock **21** befestigt.

[0033] Ein Hülsenabschnitt **46**, der aus Kunstharz gefertigt ist, ist über der unteren Oberfläche des Basisabschnitts **21**a des Gleitblocks **21** ebenso wie über den inneren Oberflächen der Einfassungen **21**b geformt, so dass dadurch das Paar von Kappenbefestigungsabschnitten **40**, **40** verbunden wird. Der Hülsenabschnitt **46** wird ebenfalls durch Einsatzgießen gleichzeitig mit dem Ausbilden der Kappenbefestigungsabschnitte **40** und der röhrenartigen Körper **45** geformt. Zusammen mit dem röhrenartigen Körper **45** befestigt der Hülsenabschnitt **46** das Paar von Kappenbefestigungsabschnitten **40**, **40** fest an dem Gleitblock **21**. Der Hülsenabschnitt **46** ist so geformt, dass er von der Lastlaufringnut **23** für die Kugeln **3** entfernt bleibt, die in dem Gleitblock **21** gebildet ist. Der Hülsenabschnitt **46** hat die Funktion des Führens eines Riemenabschnitts eines Kugelverbindungselements, das später beschrieben wird.

[0034] Bei der linearen Führungsvorrichtung werden die Kugeln **3** nicht in einer vorliegenden Formen in den endlosen Umlaufweg des Gleitstücks **2** eingeführt; vielmehr werden eine Vielzahl von Kugeln **3** in den endlosen Zirkulationsweg als Kugeln auf einer Kette **6** eingebaut, die aus einer Reihe von Kugeln besteht. **Fig.** 4 zeigt ein Beispiel der Kugeln auf einer Kette **6**. Die Kugeln auf einer Kette **6** werden aus mehreren Kugeln **3** gebildet, die in einer Reihe unter vorbestimmten Intervallen auf einen Verbindungsriemen **60** aufgefädelt werden. Der Verbindungsriemen **60** hat eine Vielzahl von Abstandshalterabschnitten **61**, die jeweils zwischen benachbarte Kugeln **3** gelegt werden. Die Abstandshalterabschnitte **61** sind miteinander durch einen Riemenabschnitt **62** verbunden. Auf beiden Seiten jedes der Abstandshalterabschnitte **61** ist ein kugelförmiger Sitz **63** geformt, der in Kontakt mit einer kugelförmigen Oberfläche der angrenzenden Kugel **3** zu bringen ist. Jede Kugel **3** wird drehbar durch ein Paar von Abstandshalterabschnitten **61** umfasst, die sich an den jeweiligen Seiten der Kugelreihe befinden. In solch einem Zustand werden mehrere Kugeln **3** miteinander durch den Verbindungsriemen **60** verbunden. Wie es in **Fig.** 3 gezeigt ist, werden die Kugeln **3** in jeden endlosen Umlaufweg des Gleitstücks **2** in der Form einer einzelnen Kugelkette **6** eingeführt. Um das Auftreten eines Knicks in dem Verbindungsriemen **60** zu vermeiden, während die Kugeln **3** in dem Zirkulationsweg umlaufen, ist ein Paar von Stützen **67** in der inneren Umfangsoberfläche des röhrenartigen Körpers **45** aus Kunststoff gebildet, der den Rückkehrweg **24** bildet, in der Richtung, in der die Kugeln **3** laufen. Der Riemenabschnitt **62** des Verbindungsriemens **60** wird entlang der Schlitze **47** geführt. Ähnliche Schlitze **48** sind in den Gebieten des Hülsenabschnitts **46** geformt, die auf beiden Seiten jeder Lastlaufringnut **23** des Gleichrings **21** positioniert sind.

[0035] **Fig.** 5 ist eine vergrößerte Querschnittsansicht, die eine Verbindung zwischen dem Lastgebiet und dem U-Kehrenweg **25** innerhalb des endlosen Umlaufwegs zeigt. Nachdem sie durch den U-Kehrenweg **25** in einem Nichtlastzustand gerollt sind, in dem keine Last auf die Kugeln **3** aufgebracht wird, rollen die Kugeln **3** in ein Lastgebiet zwischen der Lastlaufringnut **23** des Gleitstücks **2** und der Laufringnut **11** der Spurschiene **1**. In dem Lastgebiet rollen die Kugeln, wobei sie die Last aufnehmen, die auf das Gleitstück **2** aufgebracht wird. Der innere Durchmesser des U-Kehrenwegs **25**, der ein Nichtlastgebiet ist, ist so festgelegt, dass er etwas größer als der Durchmesser der Kugel **3** ist. Selbstverständlich ist auch der Eingang des U-Kehrenwegs **25**, insbesondere ein Abstand d1, zwischen der Seitenwandoberfläche **50** am inneren Durchmesser des U-Kehrenwegs **25** und der Laufringnut **11** der Spurschiene **1** ebenfalls so festgesetzt, dass er etwas größer ist als der Durchmesser der Kugel **3**. Im Gegensatz dazu sind im Lastgebiet die Kugeln **3** zwischen der Lastlaufringnut **23** des Gleitstücks **2** und der Laufringnut **11** der Spurschiene **1** eingeschlossen, wobei sie eine Last aufnehmen. Ein maximaler Abstand d2 zwischen der Lastlaufringnut **23** und der Laufringnut **11** ist im wesentlichen identisch zum Durchmesser der Kugel **3**. Wenn Last auf das Gleitstück **2** ausgeübt wird oder eine Vorlast auf die Kugeln **3** auferlegt wurde, wird der Abstand d2 kleiner als der Durchmesser der Kugel **3**. Wenn somit die Lastlaufringnut **23** vollständig parallel zur Spurschiene **1** über die gesamte Länge des Lastgebiets geformt ist, werden die Kugeln **3**, die aus dem Nichtlastgebiet in das Lastgebiet eintreten, in einem Grenzgebiet zwischen den Gebieten komprimiert, wodurch eine gleichmäßige Zirkulation der Kugeln **3** behindert wird. Wie es in **Fig.** 5 gezeigt ist, ist ein Keilgebiet A in der Lastlaufringnut **23** an beiden Enden des Lastgebiets vorgesehen. Der Abstand zwischen der Lastlaufringnut **23** und der Laufringnut **11** ist so festgesetzt, dass er sich graduell verbreitert mit Annäherung auf den U-Kehrenweg **25**. Durch das Vorhandensein des Keilgebiets A in der Lastlaufringnut **23** werden die Kugeln **3**, die in das Lastgebiet von dem Nichtlastgebiet eingetreten sind, graduell komprimiert, wobei sie sich vorwärts bewegen, und können Last aufnehmen, so dass dadurch eine gleichmäßige Zirkulation der Kugeln **3** erreicht wird und Geräusche verringert werden.

[0036] Eine Führung nach oben **49** ist am Ende der Führungsnut **43** der Endkappe **22** benachbart zum Ende der Spurschiene **1** zum Führen der Kugeln **3** geformt, so dass sie von der Laufringnut **11** der Spurschiene **1** ausgeht. Nachdem sie aus der Last beim Eintritt in den U-Kehrenweg **25** aus dem Lastgebiet freigegeben sind, entfernen sich die Kugeln **3** aus der Laufringnut **11** der Spurschiene **1** durch die Führung nach oben **49** und rollen in der Tiefe des im wesentlichen U-kehrenförmigen Wegs **25**.

[0037] Der halbkreisförmige Führungsabschnitt **42**, der am inneren Durchmesser des U-Kehrenwegs **25** positioniert ist, ist an dem Gleitblock **21** durch Spritzguss auf die oben beschriebene Weise befestigt. Es ist schwierig, vollständig den Längsrand der Lastlaufringnut **23** mit der Seitenwandoberfläche **50** des U-Kehrenwegs **25** auszurichten, der in dem Führungsabschnitt **42** geformt ist. Wenn keine vollständige Übereinstimmung zwischen der Lastlaufringnut **23** und dem U-Kehrenweg **25** vorhanden ist und wenn die Lastlaufringnut **23** von der Seitenwandoberfläche **50** in Richtung auf die Spurschiene **1** vorsteht, kommen die Kugeln **3**, die in das Lastgebiet aus dem U-Kehrenweg **25** gelangt sind, zur Kollision mit dem Rand der Lastlaufringnut **23**, selbst wenn das Keilgebiet A auf die oben beschriebene Weise vorgesehen wird. Wie es oben beschrieben worden ist, wird eine gleichmäßige Zirkulation der Kugeln **3** behindert und möglicherweise treten Geräusche als Folge der abrupten Kollision der Kugel **3** mit der Lastlaufringnut **23** auf.

[0038] Wie es in **Fig.** 5 gezeigt ist, ist es beabsichtigt, die lineare Führungsvorrichtung gemäß der vorliegenden Erfindung mit dem gestuften Abschnitt **51** zu versehen, so dass der Rand der Lastlaufringnut **23** niedriger wird als die Seitenwandoberfläche **50** am inneren Durchmesser des U-Kehrenwegs **25**. Selbst wenn Fehler beim Ausbilden des Führungsabschnitts **42** oder beim Ausbilden der Lastlaufringnut **23** vorhanden sind, wird verhindert, dass die Lastlaufringnut **23** von der Seitenwandoberfläche **50** der U-Kehrenwegs **25** in Richtung auf die Spurschiene **1** vorsteht. Die Größe des gestuften Abschnitts **51** ist etwa 5% des Durchmessers der Kugel **3**. Als Folge kann verhindert werden, dass die Kugeln **3**, die das Lastgebiet aus dem U-Kehrenweg **25** betreten, mit dem Rand der Lastlaufringnut **23** kollidieren, so dass dadurch eine gleichmäßige Zirkulation der Kugeln **3** erreicht wird. Eine solche Konstruktion ist in einem Fall effektiv, in dem die Kugeln **3** mit beträchtlich hoher Geschwindigkeit innerhalb des endlosen Umlaufwegs laufen. Selbst wenn das Gleitstück **2** mit einer hohen Geschwindigkeit relativ zur Spurschiene **1** läuft, kann eine lineare Führungsvorrichtung, die solche eine Konstruktion anwendet, bewirken, dass das Gleitstück **2** sich mit beträchtlich geringem Widerstand bewegt und sie kann das Erzeugen von Geräuschen minimieren, die andernfalls beim Bewegen der Kugeln **3** hervorgerufen würden.

[0039] Wenn der gestufte Abschnitt **51**, wie der oben beschriebene, vorhanden ist, steht der Rand der Seitenwandoberfläche **50** des U-Kehrenwegs **25** über die Lastlaufringnut in Richtung auf die Spurschiene **1** vor. Eine Breite d1 des Eingangs des U-Kehrenwegs **25** ist größer als der Durchmesser der Kugel **3**, wie es oben erwähnt wurde. Wenn die Kugeln den U-Kehrenweg **25** aus dem Lastgebiet betreten, werden die Kugeln **3** somit nicht durch den gestuften Abschnitt **51** gebremst. Der Führungsabschnitt **49** nach oben, der in der Endkappe **22** geformt ist, ist in einer Position vorgesehen, in der die Kugel **3** in Kontakt mit dem Führungsabschnitt **49** gelangt, nachdem sie aus der Last beim Eingang in den U-Kehrenweg **25** freigegeben wurde. Selbst nachdem sie aus der Last freigegeben wurde, rollt die Kugel **3** über die Laufringnut **11** der Spurschiene **1**, bis sie den oberen Führungsabschnitt **49** erreicht. Selbst in diesem Bezug besteht keine Möglichkeit, dass die Kugel **3**, die in das Nichtlastgebiet aus dem Lastgebiet gelangt, durch den gestuften Abschnitt **51** gefangen wird.

[0040] Wenn es nicht beabsichtigt wird, den gestuften Abschnitt **51** zu formen, wird das Keilgebiet A der Lastlaufringnut **23** wieder geschliffen, nachdem der Führungsabschnitt **42** auf der Endfläche des Gleitblocks **21** durch Spritzgießen geformt worden ist, so dass der Rand der Lastlaufringnut **23** justiert werden kann, so dass er mit der Seitenwandoberfläche **50** des Führungsabschnitts **42** übereinstimmt. Diese Arbeiten werden durch Verwendung eines Fräsgeräts durchgeführt. Wenn das Keilgebiet A der Lastlaufringnut **23** wieder geschliffen wird, kann eine vollständige Übereinstimmung zwischen der Lastlaufringnut **23** und der Seitenwandoberfläche **50** am inneren Durchmesser des U-Kehrenwegs **25** erreicht werden, ohne dass eine Stufe vorhanden wäre, wie es in **Fig.** 6 gezeigt ist. Somit können die Lastlaufringnut **23** und die Seitenwandoberfläche **50** kontinuierlich gestaltet werden. Somit kann eine gleichmäßige Zirkulation der Kugeln **3** sichergestellt werde, wie im Fall, in dem der gestufte Abschnitt **51** gebildet wird.

[0041] Die Ausführungsform wurde unter Verwendung der Zeichnungen beschrieben, die ein Beispiel zeigen, in dem der · Führungsabschnitt **42** am inneren Durchmesser des U-Kehrenwegs integral mit einem metallischen Gleitblock gegossen ist. Selbst im Fall einer linearen Führungsvorrichtung, bei der der Führungsabschnitt an dem Gleitblock in Verbindung mit der Endkappe befestigt ist, kann jedoch eine glatte Zirkulation der Kugeln durch Anwenden der vorliegenden Erfindung erreicht werden. Bei der Ausführungsform ist die Spurschiene **1** linear geformt. Die Spurschiene **1** kann jedoch in der Gestalt einer Kurve mit einer Krümmung gebildet werden.

[0042] Wie es beschrieben worden ist, gelangen bei der linearen Führungsvorrichtung gemäß der vorliegenden Erfindung Wälzkörper, die in ein Lastgebiet aus einem U-Kehrenweg gelangen sollen, gleichmäßig in das Lastgebiet aus einem Nichtlastgebiet und umgekehrt, ohne dass sie durch den Rand einer Lastlaufringoberfläche gebremst werden. Wenn die Wälzkörper mit einer hohen Geschwindigkeit innerhalb eines endlosen Umlaufwegs rollen, kann somit das Auftreten von Widerstand oder Geräuschen verhindert werden, was andernfalls durch das Rollen hervorgerufen würde. Es kann eine beträchtlich gleichmäßige und ruhige Hochgeschwindigkeitsrelativbewegung zwischen einem Gleitstück und einer Spurschiene erreicht werden.

Patentansprüche

1. Führungsvorrichtung, umfassend:
eine Spurschiene, die Laufringoberflächen für Wälzkörper in einer Längsrichtung von ihr geformt hat;
ein Gleitstück, das eine Lastlaufringoberfläche gegenüber der Laufringoberfläche und einen Rückkehrweg für Wälzkörper hat, der parallel zur Lastlaufringoberfläche angebracht ist; das ein Paar von Richtungsumkehrwegen hat, die einen endlosen Zirkulationsweg für Wälzkörper durch Verbinden der Lastlaufringoberfläche mit beiden Enden des Rückkehrwegs vervollständigen; und das an der Spurschiene so angebracht ist, dass eine Relativbewegung dazwischen möglich ist; und
mehrere Wälzkörper, die Last in einer Position zwischen einer Lastlaufringoberfläche des Gleitstücks und der Laufringoberfläche der Spurschiene aufnehmen können und die in dem endlosen Umlaufweg umlaufen;
wobei ein gestufter Abschnitt, bei dem die Lastlaufringoberfläche niedriger als eine Seitenwandoberfläche an einem inneren Durchmesser des Richtungsumkehrwegs wird, an einem Ort gebildet ist, an dem der Richtungsumkehrweg mit der Lastlaufringoberfläche verbunden ist.

2. Führungsvorrichtung, umfassend:
eine Spurschiene, die Laufringoberflächen für Wälzkörper in einer Längsrichtung von ihr gebildet hat;
ein Gleitstück, das eine Lastlaufringoberfläche gegenüber der Laufringoberfläche und einen Rückkehrweg für Wälzkörper hat, der parallel zur Lastlaufringoberfläche angebracht ist, wobei das Gleitstück ein Paar von Richtungsumkehrwegen hat, die einen endlosen Umlaufweg für Wälzkörper durch Verbinden der Lastlaufringoberfläche mit beiden Enden des Rückkehrwegs vervollständigen, und wobei das Gleitstück an der Spurschiene so angebracht ist, dass eine Relativbewegung dazwischen ermöglicht wird; und
mehrere Wälzkörper, die Last in einer Position zwischen einer Lastlaufringoberfläche des Gleitstücks und der Laufringoberfläche der Spurschiene aufnehmen können und die in dem endlosen Umlaufweg umlaufen;
wobei ein Ort, an dem der Richtungsumkehrweg mit der Lastlaufringoberfläche verbunden ist, so geschliffen ist, dass eine Seitenwandoberfläche an einem inneren Durchmesser der Richtungsumkehrwegs kontinuierlich zur Lastlaufringoberfläche wird.

3. Führungsvorrichtung nach Anspruch 1 oder 2, wobei das Gleitstück umfasst:
einen metallischen Gleitblock, der die Lastlaufringoberfläche und den Rückkehrweg darauf gebildet hat; und
ein Paar von Kunststoffendkappen, die an den jeweiligen Enden des Gleitblocks befestigt sind und jeweils den Richtungsumkehrweg darin gebildet haben.

DE 101 44 917 A 1

DE 101 44 917 A 1

Beschreibung

[0001] Die vorliegende Erfindung betrifft eine Rollführungsvorrichtung, bei der ein Block und eine Schiene relativ linear im Eingriff miteinander über Reihen von endlos zirkulierenden Rollelementen bewegbar sind, deren Herstellungsverfahren und eine Antriebsvorrichtung mit der Rollführungsvorrichtung.

[0002] Bisher war eine Rollführungsvorrichtung bekannt, bei der ein Block und eine Schiene linear bewegbar im Eingriff miteinander über ein Vielzahl von Rollelementen mit endlos zirkulierenden Kugeln und Rollen sind. Wie in **Fig.** 8 gezeigt ist, hat die Rollführungsvorrichtung genauer gesagt eine Schiene **80**, einen Block **90** mit einem Einschnitt **93**, der an einer unteren Fläche davon ausgebildet ist, an die die Schiene **80** passt, und eine Anzahl von Rollelementen **100**, die zwischengesetzt sind, um eine Reihe zwischen einer Rollelementrollfläche **81** und der Schiene **80** auszubilden, und eine Lastrollelementrollfläche **91** des Blocks **90**.

[0003] Hier ist der Block **90** mit Rollelementauslasslöchern **94** versehen, durch die die Rollelemente **100**, die zwischen jedem Paar der Rollelementrollfläche **81** und der Lastrollelementrollfläche **91** hindurchgetreten sind, ausgelassen werden und zu einer Ursprungsposition erneut zurückgeführt werden, um einen endlosen Zirkulationsdurchgang der Rollelemente **100** auszubilden.

[0004] Wenn des weiteren der Block **90** linear relativ entlang der Schiene **80** belegt wird, werden die Rollelemente **100** linear bewegt, während sie zwischen der Rollelementrollfläche **81** und der Lastrollelementrollfläche **91** rollen, treten zwischen der Rollelementrollfläche **81** und der Lastrollelementrollfläche **91** hindurch, werden zu dem Rollelementauslassloch **94** durch einen Rückführdurchgang zurückgeführt, der an einer nicht gezeigten Endplatte vorgesehen ist, und dann wieder zwischen der Rollelementrollfläche **81** und der Lastelementrollfläche **91** zugeführt. Für den Fall jedoch, dass der Block **90** feststehend ist und die Schiene **80** bei der vorstehend genannten Rollführungsvorrichtung bewegt wird und wenn ein schweres Stück an einem Schienenspitzenabschnitt der nach vorn gerichteten Seite der Schiene **80** in **Fig.** 8 installiert wird und ein Lastmoment darauf aufgebracht wird, trägt die Last zu einer ungleichmäßigen Verformung an dem Block **90** bei, so dass ein Verformungsbetrag (ein Öffnungsbetrag des Einschnitts **93**) an der nach vorn gerichteten Seite und der nach hinten gerichteten Seite des Blocks **90** in **Fig.** 8 variiert wird, was zu einem Problem dahingehend führt, dass die Positionsgenauigkeit der Schiene **80** verschlechtert wird.

[0005] Um dieses Problem zu lösen, kann anstelle des Einschnitts **93** ein Durchgangsloch an der Mitte des Blocks **90** vorgesehen werden, um die Schiene **80** durch das Innere des Durchgangslochs hindurchzuführen. Im Falle dieses Aufbaus wird auch für den Fall, dass eine ungleichmäßige Last auf eine Seite der Schiene **80** aufgebracht wird und das Lastmoment erzeugt wird, der Einschnitt **93** nicht geöffnet werden, so dass die Schiene **80** ständig sicher gehalten werden kann.

[0006] Sogar bei der Rollführungsvorrichtung jedoch, die so aufgebaut ist, ist es erforderlich, dass Bearbeitungspositionen der gegenüberliegenden Rollelementrollfläche **81** und der Lastrollelementrollfläche **91** auf verschiedene Positionen (verschiedene Berührwinkelpositionen) gemäß dem Verwendungszweck geändert werden, und daher muss die Gestalt einer Öffnung **25** des Blocks **90** und die äußere Gestalt der Schiene **80** ebenso gemäß der vorstehend genannten Änderung geändert werden, wobei sich dadurch ein kompliziertes Problem ergibt.

[0007] Daher ist es eine Aufgabe der vorliegenden Erfindung, eine Rollführungsvorrichtung zu schaffen, bei der auch dann, wenn ein großes Moment auf eine Schiene aufgebracht wird, ein Block nicht verformt wird, und auch wenn Bearbeitungspositionen einer Rollelementrollfläche **81** und einer Lastrollelementrollfläche **91** gleichzeitig geändert werden, es nicht erforderlich ist, die Gestalt des Blocks und der Schiene selbst zu ändern, ein Herstellungsverfahren davon und eine Antriebsvorrichtung mit der Rollführungsvorrichtung zu schaffen.

[0008] Ein erster Gesichtspunkt der vorliegenden Erfindung ist auf eine Rollführungsvorrichtung gerichtet, die eine Schiene hat, bei der eine Rollelementrollfläche entlang ihrer längsgerichteten Richtung ausgebildet ist, einen Block, bei dem eine Öffnung mit einem Durchgangsloch ausgebildet ist, wobei die Schiene an diese Öffnung angepasst ist, und ein Rollelementzirkulationsdurchgang mit einer Lastrollelementrollfläche entsprechend der Rollelementrollfläche der Schiene ausgebildet ist, und einer Vielzahl von Rollelementen, die in dem Rollelementzirkulationsdurchgang angeordnet und eingefasst sind und gemäß der relativen Bewegung der Schiene und des Blocks zirkulieren, wobei eine Schnittgestalt an rechten Winkeln zu der längsgerichteten Richtung der Schiene und eine Schnittgestalt der Öffnung des Blocks in wechselseitig geometrisch ähnlicher Längsgestalt ausgebildet sind. Auf diese Weise ist die Öffnung des Blocks zu einem Durchgangsloch ausgebildet, und daher ist der Block eine Kastenbauart einer hohen Steifigkeit, der nicht verformt wird, so dass es möglich ist, eine befriedigende Positionsgenauigkeit der Schiene ausreichend aufrechtzuerhalten, auch wenn ein großes Moment darauf aufgebracht wird. Außerdem wird es gemäß der vorliegenden Erfindung durch geeignetes Ändern der Bearbeitungspositionen einzig der Rollelementrollfläche und der Lastrollelementrollfläche möglich, einen Berührwinkel der Rollelemente durch eine Bauart eines Blocks und einer Schiene optional zu ändern. Daher ist es auch für den Fall, dass der Zweck der Verwendung und die Bedingung der Verwendung durch den Anwender verschieden sind, möglich, diese Situationen zu bewältigen, wobei dadurch die Herstellung der Rollführungsvorrichtung einfach und bei niedrigen Kosten ermöglicht wird.

[0009] Ein zweiter Gesichtspunkt der vorliegenden Erfindung ist auf die Rollführungsvorrichtung gerichtet, bei der die Schnittgestalt bei rechten Winkeln zu der längsgerichteten Richtung der Schiene und die Schnittgestalt der Öffnung des Blocks wechselweise in einer gekrümmten Linie bezüglich eines Teils ausgebildet sind, an dem die Rollelementrollfläche und die Lastelementrollfläche ausgebildet sind. Auf diese Weise ist es durch Ausbilden des Teils von beiden Schnittgestalten in eine gekrümmte Linie möglich, den Berührwinkel einfach durch Ändern der Positionen der Rollelementrollfläche und der Lastrollelementrollfläche zu ändern, wie vorstehend beschrieben ist.

[0010] Darüber hinaus ist es ein dritter Gesichtspunkt der vorliegenden Erfindung bei der Rollführungsvorrichtung, einen Aufbau zu schaffen, bei dem die gekrümmte Linie ein Teil einer runden Gestalt ist. Wenn die gekrümmte Linie eine runde Gestalt ist, wird die Beziehung zwischen der Position und dem Berührwinkel der vorstehend genannten Rollelementrollfläche und der Lastrollelementrollfläche am wichtigsten, da die Position von jeder Rollfläche mit einer hohen Genauigkeit geändert werden kann, wobei es damit möglich wird, den Berührwinkel mit einer hohen Genauigkeit zu ändern und festzusetzen.

[0011] Ein vierter Gesichtspunkt der vorliegenden Erfindung ist auf die Rollführungsvorrichtung gerichtet, bei der die gekrümmte Linie ein Teil einer Ellipse ist. Wenn die gekrümmte Linie eine Ellipse ist, ist die Beziehung der vorstehend genannten Rollelementrollfläche und der Lastrollelementrollfläche zu dem Berührwinkel nicht einfach, wie für den Fall der vorstehend genannten runden Gestalt, wobei es somit möglich ist, den Berührwinkel in Proportion zu der runden Gestalt einfach zu ändern.

[0012] Darüber hinaus ist ein fünfter Gesichtspunkt der vorliegenden Erfindung auf ein Herstellungsverfahren einer Rollführungsvorrichtung gerichtet, die einen Prozess des Ausbildens einer Rollelementrollfläche an einer Schiene entlang der längsgerichteten Richtung, einen Prozess des Ausbildens eines Rollelementzirkulationsdurchgangs mit einer Lastrollelementrollfläche entsprechend der Rollelementrollfläche der Schiene an einem Block, an dem eine Öffnung mit einem Durchgangsloch bearbeitet wird und einem Prozess des Einsetzens der Schiene in die Öffnung des Blocks und Anordnen sowie Einfassen einer Vielzahl von Rollelementen in den Rollelementzirkulationsdurchgang, die gemäß der relativen Bewegung der Schiene und des Blocks zirkulieren, wobei eine Schnittgestalt an rechten Winkeln zu der längsgerichteten Richtung der Schiene und eine Schnittgestalt der Öffnung des Blocks im voraus in eine wechselseitig geometrisch ähnliche längsgerichtete Gestalt bearbeitet werden, und wobei Bearbeitungspositionen von sowohl der Lastrollelementrollfläche des Blocks und der Rollelementrollfläche der Schiene geeignet geändert werden, wodurch der Berührwinkel der Rollelemente zu dem Block und der Schiene optional geändert wird.

[0013] Darüber hinaus ist ein sechster Gesichtspunkt der vorliegenden Erfindung auf eine Antriebsvorrichtung mit einer Rollführungsvorrichtung gerichtet, die eine Schiene hat, an der eine Rollelementrollfläche entlang der längsgerichteten Richtung ausgebildet ist; einem Block, an dem eine Öffnung mit einem Durchgangsloch ausgebildet ist, wobei die Schiene an diese Öffnung passt und ein Rollelementzirkulationsdurchgang einschließlich einer Lastrollelementrollfläche entsprechend der Rollelementrollfläche der Schiene ausgebildet ist; und einer Vielzahl von Rollelementen, die in dem Rollelementzirkulationsdurchgang angeordnet sowie eingefasst sind und die gemäß der relativen Bewegung der Schiene und des Blocks zirkulieren; wobei eine Schnittgestalt an rechten Winkeln zu der längsgerichteten Richtung der Schiene und eine Schnittgestalt der Öffnung des Blocks in eine wechselseitig geometrisch ähnliche längsgerichtete Gestalt ausgebildet sind, und ein Linearmotor mit einer Sekundärseite, die an den beiden Hauptseiten der Schiene angeordnet ist, und einer Primärseite, die an der Öffnung des Blocks entsprechend dieser Sekundärseite angeordnet ist, angeordnet ist.

[0014] **Fig.** 1 ist eine perspektivische schematische Teilschnittansicht einer Rollführungsvorrichtung gemäß einem Ausführungsbeispiel der vorliegenden Erfindung.

[0015] **Fig.** 2 zeigt eine Rollführungsvorrichtung gemäß einem Ausführungsbeispiel der vorliegenden Erfindung, und **Fig.** 2(a) ist eine schematische Querschnittsseitenansicht und **Fig.** 2(b) ist eine Draufsicht.

[0016] **Fig.** 3 ist eine Querschnittsansicht einer Rollführungsvorrichtung gemäß einem Ausführungsbeispiel der vorliegenden Erfindung.

[0017] **Fig.** 4 ist eine Querschnittsansicht einer Rollführungsvorrichtung, bei der Bearbeitungspositionen einzig von einer Rollelementrollfläche **11** und einer Lastrollelementrollfläche **27** geändert werden.

[0018] **Fig.** 5 ist eine Querschnittsansicht der Rollführungsvorrichtung, bei der Bearbeitungspositionen einzig von der Rollelementrollfläche **11** und der Lastrollelementrollfläche **27** geändert werden.

[0019] **Fig.** 6 ist eine Querschnittsansicht, die eine Antriebsvorrichtung gemäß der vorliegenden Erfindung zeigt.

[0020] **Fig.** 7 ist eine Querschnittsansicht, die eine andere Antriebsvorrichtung gemäß der vorliegenden Erfindung zeigt.

[0021] **Fig.** 8 ist eine Querschnittsansicht, die eine herkömmliche Rollführungsvorrichtung zeigt.

[0022] Im Folgenden werden Ausführungsbeispiele der vorliegenden Erfindung genau unter Bezugnahme auf die Zeichnungen beschrieben.

[0023] **Fig.** 1 bis **Fig.** 3 zeigen eine Rollführungsvorrichtung gemäß einem Ausführungsbeispiel der vorliegenden Erfindung, wobei **Fig.** 1 eine teilweise geschnittene perspektivische Ansicht ist, **Fig.** 2(a) eine schematische Seitenschnittansicht ist, **Fig.** 2(b) eine Draufsicht ist, und **Fig.** 3 eine Querschnittsansicht ist. Wie in diesen Zeichnungen gezeigt ist, ist die Rollführungsvorrichtung aus einer Schiene **10**, einem Block **20** und einer Kugel (Rollelement) **70** aufgebaut.

[0024] Ein Querschnitt der Schiene **10** ist eine längsgerichtete Gestalt, und obere und untere Flächen sind genauer gesagt im Wesentlichen parallele Ebenen, bei denen beide Seiten in einer im Wesentlichen elliptischen Gestalt ausgebildet sind, die mit einer bogenförmigen Gestalt vorstehen. Darüber hinaus sind oben und unten an der Schiene **10** zwei vertiefungsähnliche Rollelementrollflächen **11** rechts und links ausgebildet und daher sind vier vertiefungsähnliche Rollelementrollflächen **11** insgesamt ausgebildet.

[0025] Der Block **20** hat einen Blockkörper **21** und Endplatten **23**, die an beiden Endseiten des Blockkörpers **21** eingebaut sind. Der Blockkörper **21** ist mit einer Öffnung **25** versehen, in die die Schiene **10** eingesetzt ist, und an oberen und unteren Flächen dieser Öffnung **25** sind vier vertiefungsähnliche Lastrollelementrollflächen **27** entsprechend den jeweiligen Rollelementrollflächen **11** der Schiene **10** ausgebildet. Zwischen jeder der wechselseitig gegenüberliegenden Rollelementflächen **11** und der Lastrollelementrollfläche **27** ist eine Vielzahl von Kugeln (Rollelemente) **70**, . . . bewegbar zwischengesetzt.

[0026] Die Öffnung **25** ist ein Durchgangsloch und ihr Querschnitt ist eine längsgerichtete Gestalt, und genauer gesagt sind obere und untere Flächen im Wesentlichen parallele Ebenen, an denen beide Seiten in einer im Wesentlichen elliptischen Gestalt ausgebildet sind, die wie eine bogenförmige Gestalt vorstehen. Das heißt, dass eine Schnittgestalt an rechten Winkeln zu der längsgerichteten Richtung der Schiene **10** und eine Schnittgestalt der Öffnung **25** in einer wechselseitig geometrisch ähnlichen längsgerichteten Gestalt ausgebildet sind, für den Fall dieses Ausführungsbeispiels eine elliptische Gestalt. Daher sind die äußere Umfangsfläche der Schiene **10** und die innere Umfangsfläche der Öffnung **25** parallel und Zwischenraumabmessungen von beiden Flächen sind ungefähr die gleichen an jedem Teil.

[0027] An dem Blockkörper **21** sind zwei Rollelementauslasslöcher **51** zum Auslassen der Kugeln bei einem Lastbereich entsprechend den jeweiligen Lastrollelementrollflächen **27** oben beziehungsweise unten von der Öffnung **25** ausgebildet, und daher sind vier Löcher **51** insgesamt ausgebildet. Andererseits sind an oberen und unteren Flächen und an beiden Seiten des Blocks **21** Schraubenlöcher **29** zum Befestigen dieses Blockkörpers **21** mit anderen Elementen vorgesehen.

[0028] Die Endplatte **23** ist aus einem rechteckigen Element gebildet, das ungefähr die gleiche Gestalt hat wie die Endfläche des Blockkörpers **21**. An seiner Mitte ist eine Öffnung **53** zum Hindurchführen der Schiene **10** und ein Rückführdurchgang **55** zum Vorwärtsleiten der Kugeln **70**, die zwischen dem Blockkörper **21** und der Schiene **10** zwischengesetzt sind, in ein Rollelementauslassloch **51** in dem

Lastbereich zum erneuten Rückführen der Kugeln zu dem Lastbereich vorhanden. Außerdem ist an der äußeren Endseite der Endplatte **23** ein Abdichtungselement **57** vorgesehen, um zu verhindern, dass Schmutz in das Innere eintritt und um zu verhindern, dass Schmiermittel nach außen austritt.

[0029] Des weiteren ist ein Rollelementzirkulationsdurchgang durch die Lastrollelementrollfläche **27** entsprechend der Rollelementrollfläche **11** der Schiene **10**, das Rollelementauslassloch **51** und den Rückführdurchgang **55** definiert.

[0030] Als ein Verfahren zum Herstellen der Lastrollelementrollfläche **27** an dem Block **20** kann beispielsweise ein Verfahren verwendet werden, bei dem die Öffnung **25** an dem Block **20** durch Drahtschneiden (Erodieren) und dergleichen perforiert wird und eine Vertiefung dann an der inneren Fläche davon lediglich durch Schleifen ausgebildet wird, um die Lastrollelementrollfläche **27** zu bearbeiten.

[0031] Wenn die Schiene **10** dann linear in ihrer längsgerichteten Richtung zu dem Block **20** bewegt wird, bewegt sich die Schiene **10** sanft, wenn die Kugel **70** zwischen der Rollelementrollfläche **11** der Schiene **10** und der Lastrollelementrollfläche **27** des Blocks **20** sich bewegt, während es rollt.

[0032] Da bei der vorliegenden Erfindung die Öffnung **25** an dem Block **20** vorgesehen ist und die Schiene durch das Innere davon geleitet ist, wie beispielsweise in **Fig.** 2(a) gezeigt ist, ist der Block **20** an einem Befestigungsseitenelement **25** befestigt, auch wenn andererseits ein Bewegungsseitenelement **77** an dem Spitzenabschnitt der Schiene **10** befestigt ist und ein Lastmoment auf die Schiene aufgebracht wird, tritt ein Problem, bei dem die Öffnung **25** geöffnet und verformt wird, nicht auf und die Schiene **10** bewegt sich ständig sanft zu der gleichen Position wie für den Fall, bei dem das Bewegungsseitenelement **77** nicht verwendet wird, so dass es möglich ist, eine befriedigende Positionsgenauigkeit des Bewegungsseitenelements **77** ständig zu erhalten.

[0033] Da andererseits bei der vorliegenden Erfindung, wie vorstehend beschrieben ist, die Schnittgestalt an rechten Winkeln zu der längsgerichteten Richtung der Schiene **10** und die Schnittgestalt der Öffnung **25** in eine wechselseitig geometrisch ähnliche Ellipse ausgebildet sind, das heißt eine längsgerichtete Gestalt, ist die Zwischenraumabmessung der äußeren Umfangsfläche der Schiene **10** und der inneren Umfangsfläche der Öffnung **25** an jedem Teil ungefähr gleich. Wie in **Fig.** 4 und **Fig.** 5 gezeigt ist, können daher auch dann, wenn die gleiche Schiene und der gleiche Block wie die Schiene **10** und der Block **20** verwendet werden, die Bearbeitungspositionen der Rollelementrollfläche **11** und der Lastrollelementrollfläche **27** zu verschiedenen Positionen (verschiedenen Positionen eines Berührwinkels θ) gemäß dem Verwendungszweck geändert werden. Eine Vertiefungsbearbeitung der Rollelementrollfläche **11** und der Lastelementrollfläche **27** ist einfach, da sie lediglich durch Schleifen erzielt werden kann. Das heißt, dass gemäß dem Verwendungszweck durch Ändern der Bearbeitungspositionen von sowohl der Rollelementrollfläche **11** als auch der Lastelementrollfläche **27** auf eine geeignete Weise es ermöglicht wird, den Berührwinkel θ (θ1, θ2) der Kugel **70**, der Schiene **10** und des Blocks **20** optional zu ändern.

[0034] Jedoch sind bei dem vorliegenden Ausführungsbeispiel die rechtwinklige Schnittgestalt zu der längsgerichteten Richtung der Schiene **10** und die Schnittgestalt der Öffnung **25** des Blocks **20** wechselseitig in eine bogenförmige Gestalt ausgebildet, das heißt eine gekrümmte Linie bezüglich eines Teils, an dem die Rollelementrollfläche **11** und die Lastrollelementrollfläche **27** ausgebildet sind.

[0035] Auf diese Weise ist es durch Ausbilden des Teils von beiden Schnittgestalten in eine gekrümmte Linie möglich, den Berührwinkel einfach durch Ändern der Positionen der Rollelementrollfläche **11** und der Lastelementrollfläche **27** zu ändern, wie vorstehend beschrieben ist. Außerdem sind beide oder einer von dem Teil der Schienenschnittgestalt und der Blockschnittgestalt einer geraden Linie, wobei Ändern des Berührwinkels nicht immer einfach ist.

[0036] Bei dem vorliegenden Ausführungsbeispiel ist die vorstehend genannte gekrümmte Linie eine bogenförmige Gestalt, das heißt ein Teil einer runden Gestalt. Wenn die gekrümmte Linie eine runde Gestalt ist, wird die Beziehung der Position und des Berührwinkels der vorstehend genannten Rollelementrollfläche **11** und der Lastrollelementrollfläche **27** am wichtigsten, da die Position jeder Rollfläche in hohem Maße genau geändert werden kann, wobei es auch möglich ist, den Berührwinkel mit einer hohen Genauigkeit zu ändern und festzusetzen.

[0037] Außerdem kann die vorstehend genannte gekrümmte Linie ein Teil einer elliptischen Gestalt sein. Für den Fall einer Ellipse ist jedoch die Beziehung der vorstehend genannten Rollelementrollfläche **11** und der Lastrollelementrollfläche **27** zu dem Berührwinkel nicht so einfach wie für den Fall der vorstehend genannten runden Gestalt, wobei es somit möglich ist, den Berührwinkel in Proportion zu der runden Gestalt zu ändern.

[0038] **Fig.** 6 ist eine quergerichtete Schnittansicht, die eine Antriebsvorrichtung gemäß der vorliegenden Erfindung zeigt. Diese Antriebsvorrichtung ist so aufgebaut, dass Magneten (Sekundärseite (Sekundärkonduktor)) **60**, **60** eingebaut sind, um jeweils an oberen und unteren Flächen (prinzipiell an beiden Flächen) der Schiene **10** der Rollführungsvorrichtung desselben Aufbaus eingebettet zu sein, der in **Fig.** 4 gezeigt ist, und andererseits sind Elektromagneten (Primärseite (Stator)) **61**, **61** eingebaut, um an oberen und unteren Flächen des inneren Umfangs der Öffnung **25** des Blocks **20** eingebettet zu sein. Ein Linearmotor, der durch ein Paar aus einem Magneten **60** und einem Magneten **61** der oberen Seite ausgebildet ist, und ein Linearmotor, der durch ein Paar aus einem Magneten **60** und einem Magneten **61** der unteren Seite ausgebildet ist, sind an einer Position vorgesehen, die vertikal zu der Mitte der Schiene **10** symmetrisch ist. Als Linearmotor können Motoren von verschiedenem Aufbau, wie zum Beispiel ein linearer Direktstrommotor und ein linearer Impulsmotor, angewendet werden. Durch eine Durchströmung von Strom zu den Elektromagneten **61**, **61** wird die Schiene **10** angetrieben, um sich zu dem Block **20** vorzuschieben und zurückzuziehen.

[0039] Da bei diesem Ausführungsbeispiel die Schiene **10** durch die Öffnung **25**, die an dem Block **20** vorgesehen ist, abgedeckt ist, ist es möglich, eine Position zum Einbauen des Magneten **60** und des Elektromagneten **16** nicht nur an der Seite der oberen Fläche einzubauen, sondern auch an der Seite der unteren Fläche, das heißt an prinzipiell beiden Seiten der Schiene **10**. Daher ist es möglich, eine Verformung eines Strukturelements in radiale Richtung aufgrund der Magnetanziehung zu beschränken, so dass eine Drucklast durch Raumeinsparung aufgrund der Verwendung von zwei Paaren von Motoren erhöht wird.

[0040] **Fig.** 7 zeigt ein Ausführungsbeispiel, bei dem die Magneten **60**, **60** von der Innenseite und der Außenseite der Schiene **10**, die in **Fig.** 6 gezeigt ist, in einen Magneten integriert sind. Wenn die Befestigung zwischen der Schiene **10** und dem Magnet **60** sicher durch Verklebung oder Verschraubung und dergleichen vorgesehen werden kann, vereinfacht eine derartige Einrichtung den Aufbau und verringert die Kosten.

[0041] Ausführungsbeispiele der vorliegenden Erfindung sind vorstehend beschrieben, aber die vorliegende Erfindung ist nicht auf die vorstehenden Ausführungsbeispiele beschränkt, und verschiedene Abwandlungen sind innerhalb des Anwendungsbereichs der Ansprüche und des Anwendungsbereichs der technischen Idee möglich, die in der Beschreibung und den Zeichnungen angegeben ist. Auch für den Fall von jeder Gestalt oder einer Konstruktion oder einer Qualität eines Materials oder eines Verfahrens einer Verwendung, die nicht direkt in der Beschreibung und den Zeichnungen angegeben sind, liegen sie außerdem innerhalb des Anwendungsbereichs der technischen Idee der vorliegenden Erfindung, solange sie die Funktion und die Wirkung der vorliegenden Erfindung demonstrieren.

[0042] Beispielsweise wird bei den vorstehenden Ausführungsbeispielen der Block **20** als die feststehende Seite und die Schiene **10** als die bewegbare Seite verwendet, wobei der Block **20** umgekehrt als die bewegbare Seite und die Schiene **10** als die feststehende Seite verwendet werden kann.

[0043] Desweiteren sind bei den vorstehenden Ausführungsbeispielen die Schnittgestalt an rechten Winkeln zu der längsgerichteten Richtung der Schiene **10** und die Schnittgestalt der Öffnung **25** des Blocks **20** wechselweise in eine runde Gestalt oder einen Teil einer elliptischen Gestalt ausgebildet, d. h. eine gekrümmte Linie, aber andere gekrümmte Linien sind anwendbar.

[0044] Desweiteren ist bei den vorstehenden Ausführungsbeispielen ein Fall gezeigt, bei dem Kugeln als Rollelemente verwendet werden, aber die vorliegende Erfindung kann auf den Fall angewendet werden, bei dem Rollen bzw. Walzen bei einem ähnlichen Aufbau verwendet werden.

[0045] Somit ist die Schiene **10** vorgesehen, an der die Rollelementrollfläche **11** entlang der längsgerichteten Richtung ausgebildet ist, der Block **20**, an dem die Lastrollelementrollfläche **27** an der Öffnung **25** mit dem Durchgangsloch ausgebildet ist, der Vielzahl von Kugeln **70** zwischen der Rollelementrollfläche **11** und der Lastelementrollfläche **27** angeordnet und eingefasst ist, die gemäß der relativen Bewegung der Schiene **10** und **11** des Blocks **20** zirkulieren. Die zu der längsgerichteten Richtung der Schiene **10** rechtwinklige Schnittgestalt und die Schnittgestalt der Öffnung **25** sind in einer wechselseitig geometrisch ähnlichen längsgerichteten Gestalt ausgebildet. Der Block **20** ist eine Kastenbauart mit hoher Steifigkeit. Ein Berührwinkel der Kugel **70** kann durch Ändern der Position einzig der Rollelementrollfläche **11** und der Lastrollelementrollfläche **27** geändert werden, die an der Bauart des Blocks **20** und der Schiene **10** bearbeitet werden sollen.

Patentansprüche

1. Rollführungsvorrichtung mit:
einer Schiene, an der eine Rollelementrollfläche entlang ihrer längsgerichteten Richtung ausgebildet ist,
einem Block, an dem eine Öffnung mit einem Durchgangsloch ausgebildet ist, wobei die Schiene an diese Öffnung angepasst ist, und ein Rollelementzirkulationsdurchgang mit einer Lastrollelementrollfläche entsprechend der Rollelementrollfläche der Schiene ausgebildet ist, und
einer Vielzahl von Rollelementen, die in dem Rollelementzirkulationsdurchgang angeordnet und eingefasst sind und die gemäß der relativen Bewegung der Schiene und des Blocks zirkulieren, wobei
eine zu der längsgerichteten Richtung der Schiene rechtwinklige Schnittgestalt und eine Schnittgestalt der Öffnung des Blocks in eine wechselseitig geometrisch ähnliche längsgerichtete Gestalt ausgebildet sind.

2. Rollführungsvorrichtung gemäß Anspruch 1, dadurch gekennzeichnet, dass die zu der längsgerichteten Richtung der Schiene senkrechte Schnittgestalt und die Schnittgestalt der Öffnung des Blocks wechselseitig in eine gekrümmte Linie bezüglich eines Teils ausgebildet sind, an dem die Rollelementrollfläche und die Lastrollelementrollfläche ausgebildet sind.

3. Rollführungsvorrichtung gemäß Anspruch 2, dadurch gekennzeichnet, dass die gekrümmte Linie ein Teil einer runden Gestalt ist.

4. Rollführungsvorrichtung gemäß Anspruch 2, dadurch gekennzeichnet, dass die gekrümmte Linie ein Teil einer Ellipse ist.

5. Herstellungsverfahren einer Rollführungsvorrichtung mit:
einem Schritt des Ausbildens einer Rollelementrollfläche an einer Schiene entlang der längsgerichteten Richtung,
einem Schritt des Ausbildens eines Rollelementzirkulationsdurchgangs mit einer Lastrollelementrollfläche entsprechend der Rollelementrollfläche der Schiene an einem Block, an dem eine Öffnung mit einem Durchgangsloch bearbeitet ist, und
einem Schritt des Einsetzens der Schiene in die Öffnung des Blocks und des Anordnens sowie Einfassens einer Vielzahl von Rollelementen in den Rollelementzirkulationsdurchgang, die gemäß der relativen Bewegung der Schiene und des Blocks zirkulieren, wobei
eine zu der längsgerichteten Richtung der Schiene senkrechte Schnittgestalt und eine Schnittgestalt der Öffnung des Blocks im Voraus in einer wechselseitig geometrisch ähnlichen längsgerichteten Gestalt bearbeitet werden und Bearbeitungspositionen von sowohl der Lastrollelementrollfläche des Blocks als auch der Rollelementrollfläche der Schiene geeignet geändert werden, wodurch der Berührwinkel der Rollelemente zu dem Block und der Schiene optional geändert wird.

6. Antriebsvorrichtung mit einer Rollführungsvorrichtung, die Folgendes aufweist:
eine Schiene, an der eine Rollelementrollfläche entlang der längsgerichteten Richtung ausgebildet ist,
einen Block, an dem eine Öffnung mit einem Durchgangsloch ausgebildet ist, wobei die Schiene an diese Öffnung passt, und ein Rollelementzirkulationsdurchgang einschließlich einer Lastrollelementrollfläche entsprechend der Rollelementrollfläche der Schiene ausgebildet ist, und
eine Vielzahl von Rollelementen, die in dem Rollelementzirkulationsdurchgang angeordnet und eingefasst sind und die gemäß der relativen Bewegung der Schiene und des Blocks zirkulieren, wobei
eine zu der längsgerichteten Richtung der Schiene rechtwinklige Schnittgestalt und eine Schnittgestalt der Öffnung des Blocks in eine wechselseitig geometrisch ähnliche längsgerichtete Gestalt ausgebildet sind, und
ein Linearmotor mit einer Sekundärseite, die an beiden Hauptseiten der Schiene angeordnet ist, und einer Primärseite, die an der Öffnung des Blocks entsprechend dieser Sekundärseite angeordnet ist, vorgesehen ist.

(54) Wälzkörper-Abstandshalter in einer Rollführungsvorrichtung

(57) Es wird ein Wälzkörper-Abstandshalter bereitgestellt, der in einer Rollführungsvorrichtung mit einer endlosen Kugelumlaufbahn eingesetzt wird und der in der endlosen Umlaufbahn abwechselnd mit vielen Kugeln angeordnet ist und zusammen mit den Kugeln in der endlosen Umlaufbahn umläuft. Er weist ein Paar Kugelpfannen auf, die jeweils in einer konkaven Kugelflächenform ausgebildet sind, die eine Kugelfläche der Kugel gut annähert und sich im Gleitkontakt mit der Kugel befindet, und um die Kugelpfanne herum ist ein ringförmiger Käfigabschnitt ausgebildet, der in Richtung der Kugelanordnung über einen Randabschnitt der Kugelpfanne vorsteht und außer Kontakt mit der auf der Kugelpfanne aufliegenden Kugel gehalten wird.

DE 101 21 311 A 1

DE 101 21 311 A 1

Beschreibung

[0001] Die Erfindung betrifft einen Wälzkörper-Abstandshalter, der in verschiedenen Rollführungsvorrichtungen mit einer endlosen Umlaufbahn, wie z. B. einer Linearführung und einer Kugelspindel, zwischen den aneinandergrenzenden Kugeln in der endlosen Umlaufbahn eingesetzt ist und die Reibung zwischen den Kugeln sowie die Wärmeentwicklung vermindert, um dadurch deren Rollbewegung zu glätten.

[0002] Als Rollführungsvorrichtung, in der ein Elementepaar fortlaufend eine Relativbewegung durch eine endlos umlaufende Kugelreihe ausführt, sind bisher Vorrichtungen bekannt, wie z. B. eine Linearführung, die als Linearführungsabschnitt in einer Werkzeugmaschine, einer Transportvorrichtung und dergleichen eingesetzt wird und die einen beweglichen Körper, wie z. B. einen Tisch, auf einem ruhenden Abschnitt führt, wie z. B. auf einem Bett oder Support, und eine Kugelspindel, die zusammen mit dieser Linearführung verwendet wird und dem beweglichen Körper einen linearen Hub erteilt, der einem Drehungsbetrag eines Motors entspricht.

[0003] Die erstere Linearführung weist eine Lagerlaufschiene auf, die auf dem ruhenden Abschnitt angeordnet ist und in der in Längsrichtung eine Laufrille für die Kugeln ausgebildet ist, sowie ein Gleitbett, das eine Lastlaufrille aufweist, die der Laufrille der Lagerlaufschiene mit vielen dazwischen angeordneten Kugeln gegenüberliegt, und in dem eine endlose Umlaufrille für die in der Lastlaufrille rollenden Kugeln ausgebildet ist, und ist so gestaltet, daß das den beweglichen Körper tragende Gleitbett zusammen mit dem endlosen Umlauf der Kugeln fortlaufend die Linearbewegung entlang der Lagerlaufschiene ausführt. Umgekehrt gibt es ferner einen Fall, wo die Linearführung so gestaltet ist, daß die Lagerlaufschiene relativ zu dem festen Gleitbett bewegt wird.

[0004] Andererseits weist die letztere Kugelspindel eine Spindelwelle auf, in der eine spiralförmige Kugellaufrille mit vorgegebener Steigung ausgebildet ist, sowie ein Gewinderingelement mit einer Lastlaufrille, die der Kugellaufrille mit vielen dazwischen angeordneten Kugeln gegenüberliegt, wobei in dem Gewinderingelement eine endlose Umlaufbahn für die in der Lastlaufrille rollenden Kugeln ausgebildet ist, wobei die Kugelspindel so gestaltet ist, daß zusammen mit einer Relativbewegung zwischen der Spindelwelle und dem Gewinderingelement die Kugeln in der endlosen Umlaufbahn umlaufen und das Gewinderingelement und die Spindelwelle sich relativ zueinander in axialer Richtung bewegen.

[0005] Da andererseits in einer derartigen Rollführungsvorrichtung die einzelne Kugel, die in der endlosen Umlaufbahn umläuft, in Kontakt mit den vor und nach ihr angeordneten Kugeln kommt, war es bei hoher Laufgeschwindigkeit der Kugel möglich, daß abgesehen vom Verschleiß der Kugeln innerhalb relativ kurzer Zeit, z. B. durch Reibung zwischen den Kugeln, ein Nachteil derart entsteht, daß die Kugel oder die Lastlaufrille infolge der Reibungswärme blokkieren bzw. sich festfressen. Ferner wird bei einer Umkehr der Bewegungsrichtung, d. h. bei einer Umkehr der Umlaufrichtung, eine Anordnung der Kugeln in der endlosen Umlaufbahn wahrscheinlich gestört, und in einem Extremfall entsteht eine sogenannte Blockierungserscheinung, bei der sich die Kugeln in der endlosen Umlaufbahn stauen, so daß die Möglichkeit besteht, daß der Betrieb der Linearführung selbst unmöglich wird. Zur Beseitigung derartiger Nachteile wird daher in JP-A-315 853/1999 eine Linearführung offenbart, in der ein Wälzkörper-Abstandshalter zwischen den aneinandergrenzenden Kugeln in der endlosen Umlaufbahn eingefügt ist.

[0006] Die in der obigen Patentschrift offenbarte Linearführung ist so angepaßt, daß ein aus Kunstharz hergestellter Wälzkörper-Abstandshalter, der als Trennstück bzw. Abstandshalter bezeichnet wird, abwechselnd mit der Kugel in der endlosen Umlaufbahn angeordnet ist und dadurch eine gegenseitige Berührung der Kugeln verhindert. Ein solcher Abstandshalter ist in einer scheibenartigen Form ausgebildet, deren äußerer Durchmesser kleiner als ein Kugeldurchmesser ist, und an seiner Vorder- und Rückseite, die beide mit den Kugeln in Kontakt kommen, sind Kugelpfannen ausgebildet, deren Krümmungen größer sind als die Krümmung einer Kugelfläche der Kugel. Bei abwechselnder Anordnung der Kugel und des Abstandshalters ohne Zwischenraum in der endlosen Umlaufbahn wird dadurch jede Kugel zwischen einem Paar vor bzw. hinter der Kugel angrenzender Abstandshalter angeordnet, so daß sie zusammen mit den Abstandshaltern in der endlosen Umlaufbahn umläuft, ohne eine Kugelreihe zu stören, auch wenn die Umlaufrichtung umgekehrt wird.

[0007] Wenn jedoch, wie bei dem in JP-A-315 853/1999 dargestellten Wälzkörper-Abstandshalter, die im Gleitkontakt mit der Kugel befindliche Kugelpfanne als konkav gekrümmte Fläche ausgebildet ist, deren Krümmung größer als die der Kugelfläche der Kugel ist, dann schaukelt bzw. wackelt die Kugel in dem Wälzkörper-Abstandshalter, da zwischen einem Randabschnitt am Umfang der Kugelpfanne und der Kugel ein Zwischenraum entsteht, so daß sich das Problem ergibt, daß eine Mäanderbewegung der Kugeln in der endlosen Umlaufbahn unmöglich völlig auszuschließen ist.

[0008] Andererseits ist es unter dem Gesichtspunkt der Verhinderung der Mäanderbewegung der Kugeln in der endlosen Umlaufbahn notwendig, daß sich die Kugel auf der Kugelpfanne des Wälzkörper-Abstandshalters ohne Schaukeln einspielt, und daher muß die Kugelpfanne in einer konkaven Kugelflächenform ausgebildet sein, welche die Kugelfläche der Kugel gut annähert. Falls jedoch die Kugelpfanne in einer solchen konkaven Kugelflächenform ausgebildet ist, entsteht eine große Kontaktfläche zwischen der Kugel und der Kugelpfanne, so daß eine Zunahme des Gleitkontaktwiderstands zwischen dem Wälzkörper-Abstandshalter und der Kugel, ein vorzeitiger Verschleiß des Wälzkörper-Abstandshalters und dergleichen möglich sind.

[0009] Falls ferner die Kugelpfanne mit kleinem Durchmesser konstruiert ist, um die Zunahme des Gleitkontaktwiderstands bezüglich der Kugel zu vermeiden, dann ergibt sich der Nachteil, daß der Wälzkörper-Abstandshalter aus dem Zwischenraum zwischen den aneinandergrenzenden Kugeln herausfällt, auch wenn nur ein geringer Zwischenraum zwischen der Kugel und dem Wälzkörper-Abstandshalter entsteht.

[0010] Die Erfindung ist im Hinblick auf ein solches Problem entwickelt worden, und ihre Aufgabe besteht darin, einen Wälzkörper-Abstandshalter bereitzustellen, der einen guten Sitz der Kugel auf der Kugelpfanne ermöglicht, wodurch die Ausrichtung der Kugeln und der Wälzkörper-Abstandshalter in der endlosen Umlaufbahn stabilisiert werden soll, und der den auf die Kugel wirkenden Gleitkontaktwiderstand verringern und ein Herausfallen des Wälzkörper-Abstandshalters aus dem Zwischenraum zwischen den Kugeln wirksam verhindern kann.

[0011] Diese Aufgabe wird mit den Merkmalen der Ansprüche gelöst.

[0012] Da bei einer solchen technischen Einrichtung die Kugelpfanne, mit der sich die Kugel im Gleitkontakt befindet, in der konkaven Kugelflächenform ausgebildet ist, welche die Kugelfläche der Kugel gut annähert, entsteht kaum ein Zwischenraum zwischen der Kugelfläche der Kugel und der Kugelpfanne, so daß der Sitz der Kugel auf der Kugelpfanne stabilisiert wird. Falls daher die Wälzkörper-Abstandshalter und die Kugeln abwechselnd in der endlosen Umlaufbahn der Rollführungsvorrichtung angeordnet sind, soll die Ausrichtung der Kugeln und der Wälzkörper-Abstandshalter stabilisiert werden, so daß es möglich wird, eine Mäanderbewegung der Kugeln in der endlosen Umlaufbahn zu verhindern.

[0013] Da ferner rund um die Kugelpfanne der ringförmige Rückhalte- bzw. Käfigabschnitt (wörtlich: Abschnitt zur Verhinderung des Herausfallens) ausgebildet ist, der außer Kontakt mit der Kugel gehalten wird, und der Käfigabschnitt in Richtung der Kugelanordnung über den Randabschnitt der Kugelpfanne vorsteht, wird es möglich, ein Herausfallen des Wälzkörper-Abstandshalters von vornherein dadurch zu verhindern, daß der Käfigabschnitt mit der Kugel in Eingriff kommt, selbst wenn ein Zwischenraum zwischen der Kugel und dem Wälzkörper-Abstandshalter entsteht und daher ein Herausfallen des Wälzkörper-Abstandshalters aus dem Zwischenraum zwischen aneinandergrenzenden Kugeln wahrscheinlich wird. Da ein Durchmesser der Kugelpfanne ohne Rücksicht auf das Herausfallen des Wälzkörper-Abstandshalters festgelegt werden kann und daher die Kugelpfanne so klein wie nötig ausgebildet werden kann, wird es dementsprechend möglich, eine kleine Kontaktfläche zwischen der Kugelpfanne und der Kugel herzustellen, wodurch der auf die Kugel wirkende Gleitkontaktwiderstand verringert wird. Da ferner der Käfigabschnitt bei auf der Kugelpfanne aufliegender Kugel außer Kontakt mit der Kugel gehalten wird, nimmt der auf die Kugel wirkende Gleitkontaktwiderstand in keinem Fall durch die Bereitstellung des Käfigabschnitts zu.

[0014] Falls die Kugelpfanne in der konkaven Kugelflächenform ausgebildet ist, welche die Kugelfläche der Kugel gut annähert, wird ein an der Kugel anhaftendes Schmiermittel durch einen Randabschnitt am Umfang der Kugelpfanne abgeschabt, da der Umfangsrandabschnitt in Kontakt mit der Kugelfläche der Kugel kommt, so daß die Kugel wahrscheinlich einen Zustand mit unzureichender Schmierung annimmt. Da jedoch bei dem erfindungsgemäßen Wälzkörper-Abstandshalter der rund um die Kugelpfanne vorgesehene Käfigabschnitt außer Kontakt mit der Kugelfläche der Kugel gehalten wird, tritt das Schmiermittel wahrscheinlich in den Zwischenraum zwischen dem Käfigabschnitt und der Kugel ein, so daß auch dann ein guter Schmierungszustand der Kugel aufrechterhalten werden kann, wenn die Kugelpfanne in der konkaven Kugelflächenform ausgebildet ist, welche die Kugelfläche der Kugel gut annähert. Dementsprechend ist es im Hinblick auf die Aufrechterhaltung eines guten Schmierungszustands des erfindungsgemäßen Wälzkörper-Abstandshalters vorzuziehen, wenn zwischen der Kugelpfanne und dem sie umgebenden Käfigabschnitt eine ringförmige Rille ausgebildet wird und diese ringförmige Rille als Schmiermittelsumpf verwendet wird. Da bei einem derartigen Aufbau das Schmiermittel, das in den Zwischenraum zwischen der Kugel und dem Käfigabschnitt fließt, in der ringförmigen Rille gespeichert wird, kann immer Schmiermittel auf die Kugeloberfläche aufgebracht werden.

[0015] Da es andererseits schwierig ist, in der endlosen Umlaufbahn der Rollführungsvorrichtung einen Zwischenraum zwischen der Kugel und dem Wälzkörper-Abstandshalter völlig zu beseitigen, folgt daraus, daß der Wälzkörper-Abstandshalter und die Kugel während eines Umlaufs der Kugeln immer wieder ein wenig zusammenstoßen. Im Hinblick darauf, eine Ermüdung und ein Stoßgeräusch der Kugeln zu vermindern, die auf derartige Stöße zurückzuführen sind, sollte die Kugelpfanne, mit der sich die Kugel im Gleitkontakt befindet, vorzugsweise aus einem entsprechend weichen Material bestehen. Dagegen darf sich der Käfigabschnitt, da er das Herausfallen des Wälzkörper-Abstandshalters aus dem Zwischenraum zwischen aneinandergrenzenden Kugeln verhindern soll, beim Auftreten einer solchen Situation nicht ohne weiteres durch Stöße der Kugel verformen, so daß er vorzugsweise aus einem harten Material bestehen sollte. Unter diesem Gesichtspunkt sollten dementsprechend die Kugelpfanne und der Käfigabschnitt, die in dem erfindungsgemäßen Wälzkörper-Abstandshalter vorgesehen sind, vorzugsweise aus verschiedenen Harzmaterialien geformt werden, wobei der Käfigabschnitt vorzugsweise aus einem härterem Harzmaterial als die Kugelpfanne geformt wird.

[0016] Übrigens kann der Käfigabschnitt in einer fugenlosen Ringform ausgebildet werden, kann aber auch mit einem in der Ringform durch einen Schlitz abgetrennten Vorsprung hergestellt werden.

[0017] Da, wie oben erläutert, bei dem erfindungsgemäßen Wälzkörper-Abstandshalter jedes Kugelpfannenpaar, mit dem sich die Kugeln im Gleitkontakt befinden, in der konkaven Kugelflächenform ausgebildet wird, welche die Kugelfläche der Kugel gut annähert, und da rund um jede Kugelpfanne der ringförmige Käfigabschnitt ausgebildet ist, der in Richtung der Kugelanordnung über den Randabschnitt der Kugelpfanne vorsteht und außer Kontakt mit der auf der Kugelpfanne aufliegenden Kugel gehalten wird, ist es möglich, die Ausrichtung der Kugeln und der Wälzkörper-Abstandshalter in der endlosen Umlaufbahn zu stabilisieren und dabei einen guten Sitz der Kugel auf der Kugelpfanne zu erreichen, um den auf die Kugel wirkenden Gleitkontaktwiderstand zu verringern, und außerdem wird es möglich, das Herausfallen des Wälzkörper-Abstandshalters aus dem Zwischenraum zwischen den Kugeln wirksam zu verhindern.

[0018] **Fig.** 1 zeigt eine seitliche Schnittansicht, die eine Ausführungsform einer Kugelspindelvorrichtung darstellt, in der erfindungsgemäße Wälzkörper-Abstandshalter zusammen mit Kugeln in einer endlosen Umlaufbahn angeordnet sind;

[0019] **Fig.** 2 zeigt eine Schnittansicht von vorn der in **Fig.** 1 dargestellten Kugelspindelvorrichtung;

[0021] **Fig.** 4 zeigt eine Vorderansicht, die den Wälzkörper-Abstandshalter nach der ersten Ausführungsform darstellt;

[0022] **Fig.** 5 zeigt eine Schnittansicht entlang einer Linie V-V in **Fig.** 4;

[0023] **Fig.** 6 zeigt eine vergrößerte Schnittansicht, die eine Beziehung zwischen dem Käfigabschnitt des Wälzkörper-Abstandshalters nach der ersten Ausführungsform und einer Kugel darstellt;

[0024] **Fig.** 7 zeigt eine Schnittansicht, die einen Zustand darstellt, in dem die Kugeln auf den Kugelpfannen des Wälzkörper-Abstandshalters nach der ersten Ausführungsform aufliegen;

[0025] **Fig.** 8 zeigt eine Schnittansicht, die einen Zustand darstellt, in dem die Kugeln in den Kugelpfannen des Wälzkörper-Abstandshalters nach der ersten Ausführungsform Spiel haben;

[0026] **Fig.** 9 zeigt eine Schnittansicht, die ein Beispiel des Wälzkörper-Abstandshalters nach der ersten Ausführungsform darstellt, bei dem die ringförmige Rille und der Schmierölsumpf weggelassen wurden;

[0027] **Fig.** 10 zeigt eine vergrößerte Schnittansicht, die eine Beziehung zwischen dem Käfigabschnitt des in **Fig.** 9 dargestellten Wälzkörper-Abstandshalters und der Kugel darstellt; und

[0028] **Fig.** 11 zeigt eine Schnittansicht, die eine zweite Ausführungsform des erfindungsgemäßen Wälzkörper-Abstandshalters darstellt.

[0029] Nachstehend wird ein erfindungsgemäßer Wälzkörper-Abstandshalter anhand der Zeichnungen näher erläutert.

[0030] **Fig.** 1 und **Fig.** 2 zeigen eine Ausführungsform einer Kugelspindelvorrichtung, in der die erfindungsgemäßen Wälzkörper-Abstandshalter zusammen mit Kugeln in einer endlosen Umlaufbahn angeordnet sind. In diesen Zeichnungen bezeichnet das Bezugszeichen **1** eine Spindelwelle, das Bezugszeichen **2** eine Kugel und das Bezugszeichen **3** ein Gewinderingelement, wobei das Gewinderingelement **3** über viele Kugeln **2** mit der Spindelwelle **1** im Eingriff ist.

[0031] In einer äußeren Umfangsfläche der Spindelwelle **1** ist eine spiralförmige Kugellaufrille **10** ausgebildet, während in einer inneren Umfangsfläche des Gewinderingelements **3** eine spiralförmige Lastlaufrille **30** ausgebildet ist, die der Kugellaufrille **10** der Spindelwelle **1** gegenüberliegt, und die Kugellaufrille **10** und die Lastlaufrille **30** bilden eine spiralförmige Lastkugelbahn zwischen der Spindelwelle **1** und dem Gewinderingelement **3**. Das heißt, wenn zwischen der Spindelwelle **1** und dem Gewinderingelement **3** eine relative Drehbewegung auftritt, rollt die Kugel **2** spiralförmig in der Lastkugelbahn und trägt dabei eine Last. Ferner ist an dem Gewinderingelement **3** ein Rücklaufrohr **4** angebracht, das beide Enden der Lastkugelbahn miteinander verbindet, um dadurch die endlose Umlaufbahn für die Kugeln **2** zu bilden, so daß die Kugel **2**, nachdem sie durch die Lastkugelbahn hindurchgerollt und von der Last befreit worden ist, einen lastfreien Zustand annimmt und in dem Rücklaufrohr **4** zu einem Einlaß der Lastkugelbahn zurückrollt, wobei sie mehrere Windungen der Kugellaufrille **10** überspringt. Wenn dementsprechend die Spindelwelle **1** und das Gewinderingelement **3** gegeneinander gedreht werden, folgt daraus, daß die Kugel **2** von der Lastkugelbahn zum Rücklaufrohr **4** und vom Rücklaufrohr **4** zur Lastkugelbahn rollt und innerhalb der endlosen Umlaufbahn, die durch die Lastkugelbahn und das Rücklaufrohr **4** gebildet wird, umläuft.

[0032] Um bei dieser Kugelspindelvorrichtung zu verhindern, daß die in der endlosen Umlaufbahn untergebrachten Kugeln **2** einander berühren, wird zwischen den aneinandergrenzenden Kugeln **2**, **2** ein Wälzkörper-Abstandshalter **5** eingefügt. Wie in **Fig.** 3 bis **Fig.** 5 dargestellt, wird der Wälzkörper-Abstandshalter **5** geformt, indem ein Kunstharz annähernd in Scheibenform gebracht und an seinen vorderen und hinteren Flächen jeweils Kugelpfannen **50** ausgebildet werden, mit denen sich die Kugeln **2** im Gleitkontakt befinden. Die Kugeln **2** und der Wälzkörper-Abstandshalter **5** sind in der endlosen Umlaufbahn abwechselnd angeordnet. Dadurch wird verhindert, daß die in der endlosen Umlaufbahn rollenden Kugeln **2** einander berühren, wodurch ein stoßfreier Umlauf der Kugel und dadurch eine Glättung der Drehbewegung des Gewinderingelements **3** relativ zur Spindelwelle **1** erreicht werden sollen, und außerdem wird eine Geräuschentwicklung infolge von Stößen zwischen den Kugeln während des Betriebs der Kugelspindelvorrichtung vermindert.

[0033] Die Kugelpfanne **50** ist in einer konkaven Kugelflächenform ausgebildet, welche die Kugelfläche der Kugel **2** gut annähert, und ist so gestaltet, daß die angrenzende Kugel **2** fast ohne Zwischenraum mit der Kugelpfanne **50** in Kontakt kommt. Ferner ist in der Kugelpfanne **50** ein ringförmiger Schmierölsumpf **51** ausgebildet und so angepaßt, daß eine beabsichtigte Schmierung zwischen der Kugelpfanne **50** und der Kugel **2** erfolgt. Ferner ist rund um die Kugelpfanne **50** ein ringförmiger Käfigabschnitt **52** so ausgebildet, daß er die Kugelpfanne **50** umgibt. Eine Spitze des Käfigabschnitts **52** steht in Anordnungsrichtung der Kugeln **2** (horizontale Richtung in **Fig.** 5) über einen Randabschnitt der Kugelpfanne **50** vor. Wie in **Fig.** 6 dargestellt, ist der Käfigabschnitt jedoch so angepaßt, daß bei auf der Kugelpfanne **50** aufliegender Kugel **2** ein Zwischenraum zwischen der Kugel **2** und der Spitze des Käfigabschnitts **52** ausgebildet ist. Außerdem ist zwischen dem Käfigabschnitt **52** und der Kugelpfanne **50** eine ringförmige Rille **53** ausgebildet, welche die Kugelpfanne von dem Käfigabschnitt trennt und so angepaßt ist, daß die ringförmige Rille **53** als Schmierölsumpf funktioniert.

[0034] **Fig.** 7 zeigt einen Zustand, in dem die Kugeln **2** auf den Kugelpfannen **50** des Wälzkörper-Abstandshalters **5** aufliegen. Da die Kugelpfanne **50**, wie weiter oben erwähnt, in der konkaven Kugelflächenform ausgebildet ist, welche die Kugelfläche der Kugel **2** gut annähert, berührt die aufliegende Kugel **2** die Kugelpfanne nahezu ohne Zwischenraum, wie in dieser Zeichnung dargestellt. Falls die Kugeln **2** und die Wälzkörper-Abstandshalter **50** ohne Zwischenräume in der endlosen Umlaufbahn der Kugelspindelvorrichtung angeordnet sind, führen dadurch die Kugeln **2** auf den Kugelpfannen **50** der Wälzkörper-Abstandshalter **5** keine instabile Schaukelbewegung aus, so daß die Kugeln **2** und die Wälzkörper-Abstandshalter **5** ohne Mäander- bzw. Schlängelbewegung in der endlosen Umlaufbahn umlaufen können.

[0035] Da ferner der rund um die Kugelpfanne **50** ausgebildete Käfigabschnitt **52** nicht in Kontakt mit der auf der Kugelpfanne **50** aufliegenden Kugel **2** kommt, folgt daraus, daß ein an der Kugel **2** anhaftendes Schmiermittel, wie z. B. Fett, von einem Zwischenraum zwischen dem Käfigabschnitt **52** und der Kugelfläche der Kugel **2** in die ringförmige Rille **53** eintritt und in der ringförmigen Rille **53** aufgefangen wird. Daher wird das Schmiermittel wahrscheinlich zwischen die Kugel **2** und die Kugelpfanne **50** gezogen, die miteinander im Gleitkontakt sind, so daß eine sichere Schmierung zwischen der Kugel **2** und dem Wälzkörper-Abstandshalter **5** möglich ist und außerdem das Schmiermittel wahrscheinlich auch an einer Oberfläche der Kugel **2** anhaftet, die sich nach dem Passieren der ringförmigen Rille **53** nach außen bewegt, so daß eine sichere Schmierung zwischen der Kugel **2** und der Laufrille **10** der Kugelspindelvorrichtung möglich wird.

[0036] Andererseits zeigt **Fig.** 8 einen Zustand, in dem ein Zwischenraum zwischen den aneinandergrenzenden Kugeln **2** sich während des Umlaufs in der endlosen Umlaufbahn vergrößert und daher die Kugeln **2** in den Kugelpfannen **50** des Wälzkörper-Abstandshalters **5** Spiel haben. Ein derartiger Zustand tritt irgendwo in der endlosen Umlaufbahn auf, da es schwierig ist, die Kugeln **2** und die Wälzkörper-Abstandshalter **5** beispielsweise ohne Zwischenräume bezüglich der endlosen Umlaufbahn der Kugelspindelvorrichtung anzuordnen, und weil die Kugel **2** und der Wälzkörper-Abstandshalter **5** bei langdauernder Nutzung verschleißen. Wenn die Kugeln **2** auf die obige Weise in den Kugelpfannen **50** Spiel haben, verliert außerdem der zwischen den Kugeln **2** angeordnete Wälzkörper-Abstandshalter **5** seinen Halt und versucht, aus dem Zwischenraum zwischen den Kugeln **2** herauszufallen. Da jedoch bei dem Wälzkörper-Abstandshalter **5** nach der vorliegenden Ausführungsform die Spitze des Käfigabschnitts **52** in Anordnungsrichtung der Kugeln **2** über den Randabschnitt der Kugelpfanne **50** vorsteht, kommt der bis zu diesem Zeitpunkt kontaktfreie Käfigabschnitt **52** in Eingriff mit den Kugeln **2**, wenn ein Herausfallen des Wälzkörper-Abstandshalters **5** aus dem

Zwischenraum zwischen den aneinandergrenzenden Kugeln **2** wahrscheinlich wird, und verhindert dadurch das Herausfallen des Wälzkörper-Abstandshalters **5** aus dem Zwischenraum zwischen den Kugeln **2**. Dementsprechend ist es bei dem Wälzkörper-Abstandshalter **5** nach der vorliegenden Ausführungsform nicht notwendig, einen unnötig großen Durchmesser der Kugelpfanne **50** festzusetzen, um das Herausfallen aus dem Zwischenraum zwischen den Kugeln **2** zu verhindern, so daß die Kugelpfanne **50** in der kleinsten notwendigen Größe ausgebildet werden kann. Daher kann die Kontaktfläche zwischen der Kugel **2** und der Kugelpfanne **50** verkleinert werden, so daß der Gleitkontaktwiderstand zwischen der Kugel **2** und dem Wälzkörper-Abstandshalter **5** entsprechend verringert werden kann. Im Hinblick auf die Kugelspindelvorrichtung, in der die Wälzkörper-Abstandshalter **5** in der endlosen Umlaufbahn angeordnet sind, führt dies dazu, daß eine stoßfreie Bewegung mit geringer Drehmomentschwankung erzielt wird.

[0037] Übrigens ist bei dem Wälzkörper-Abstandshalter **5** nach der obenerwähnten ersten Ausführungsform die ringförmige Rille **53** zwischen der Kugelpfanne **50** und dem Käfigabschnitt **52** ausgebildet, und der ringförmige Schmierölsumpf **51** ist in der Kugelpfanne **50** ausgebildet, aber wie in **Fig.** 9 dargestellt, können die ringförmige Rille **53** und der Schmierölsumpf **51** bei der Erfindung weggelassen werden. Selbst in diesem Fall kommt jedoch, wie in **Fig.** 10 dargestellt, der Käfigabschnitt **52** nicht in Kontakt mit der Kugelfläche der Kugel **2**, die auf der Kugelpfanne **50** aufliegt, und zwischen dem Käfigabschnitt **52** und der Kugelfläche der Kugel **2** ist ein Zwischenraum ausgebildet. Da das an der Kugel **2** anhaftende Schmiermittel, wie z. B. Fett, in den Zwischenraum eintritt, wird durch das Schmiermittel wahrscheinlich zwischen die Kugel **2** und die Kugelpfanne **50** gezogen, die miteinander im Gleitkontakt sind, so daß eine sichere Schmierung zwischen der Kugel **2** und dem Wälzkörper-Abstandshalter **5** möglich wird, wobei allerdings die im Zwischenraum enthaltene Schmiermittelmenge geringer ist als in dem Fall mit Ausbildung der ringförmigen Rille **53**.

[0038] **Fig.** 11 zeigt eine zweite Ausführungsform des erfindungsgemäßen Wälzkörper-Abstandshalters.

[0039] Bei dem Wälzkörper-Abstandshalter **5** nach der obenerwähnten ersten Ausführungsform werden die Kugelpfanne **50** und der Käfigabschnitt **52** im Spritzgußverfahren in einem Stück aus einem einzigen Kunstharz hergestellt. Bei einem Wälzkörper-Abstandshalter **6** nach der zweiten Ausführungsform werden jedoch die Kugelpfanne **50** und der Käfigabschnitt **52** jeweils aus verschiedenen Kunstharzen geformt. Da übrigens die anderen Konstruktionsmerkmale die gleichen sind wie beim Wälzkörper-Abstandshalter **5** nach der ersten Ausführungsform, werden in **Fig.** 11 die gleichen Bezugszeichen wie bei der ersten Ausführungsform zugeordnet, und ausführliche Erläuterungen der Merkmale werden hier weggelassen.

[0040] Da der Wälzkörper-Abstandshalter die Funktion eines Polsters bzw. Stoßdämpfers zwischen den aneinandergrenzenden Kugeln **2** ausübt, um dadurch die Ermüdung und Geräuschentwicklung der Kugeln **2** infolge von Stößen zu vermindern, wird die Kugelpfanne **50** vorzugsweise aus einem entsprechend weichen Material geformt, um diese Funktion in ausreichendem Maße aufweisen zu können. Da jedoch der Käfigabschnitt **52**, wenn sich ein Zwischenraum zwischen den aneinandergrenzenden Kugeln **2** vergrößert, mit der Kugel **2** in Eingriff kommt, um dadurch das Herausfallen des Wälzkörper-Abstandshalters zu verhindern, wird er vorzugsweise aus einem harten Material geformt, damit er nicht leicht deformiert wird. Hierbei kann als Richtwert bei der Auswahl eines Harzmaterials zum Formen des Käfigabschnitts und der Kugelpfanne der Biegeelastizitätsmodul eines solchen Kunstharzes gewählt werden. Das heißt, es wird berücksichtigt, daß ein Material mit niedrigem Biegeelastizitätsmodul sich leicht verformen läßt, während ein Material mit hohem Biegeelastizitätsmodul sich schwer verformen läßt.

[0041] Dementsprechend kann bei dem Wälzkörper-Abstandshalter **6** nach der zweiten Ausführungsform der Käfigabschnitt **52** im Vergleich zur Kugelpfanne **50** aus einem harten Kunstharz geformt werden, so daß die entsprechenden Teile ihre Funktionen in höchstem Grade aufweisen können.

Patentansprüche

1. Wälzkörper-Abstandshalter, der in einer Rollführungsvorrichtung verwendet wird, in der ein Elementepaar eine kontinuierliche Relativbewegung durch eine endlos umlaufende Kugelreihe ausführt, wobei der Abstandshalter zwischen Kugeln eingefügt ist, die in ihrer endlosen Umlaufbahn aneinandergrenzen, und zusammen mit den Kugeln umläuft, **dadurch gekennzeichnet**,
daß der Wälzkörper-Abstandshalter ein Paar Kugelpfannen aufweist, die jeweils in einer konkaven Kugelflächenform ausgebildet sind, die eine Kugelfläche der Kugel gut annähert und sich im Gleitkontakt mit der Kugel befindet, und
daß um jede Kugelpfanne herum ein ringförmiger Käfigabschnitt ausgebildet ist, der in Richtung der Kugelanordnung über einen Randabschnitt der Kugelpfanne vorsteht und außer Kontakt mit der auf der Kugelpfanne aufliegenden Kugel gehalten wird.
2. Wälzkörper-Abstandshalter nach Anspruch 1, dadurch gekennzeichnet, daß zwischen der Kugelpfanne und dem Käfigabschnitt eine ringförmige Rille ausgebildet ist und daß die ringförmige Rille als Schmierölsumpf dient.
3. Wälzkörper-Abstandshalter nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß in der Kugelpfanne ein Schmierölsumpf ausgebildet ist.
4. Wälzkörper-Abstandshalter nach Anspruch 1, 2 oder 3, wobei die Kugelpfanne und der Käfigabschnitt aus verschiedenen Harz- oder Kunststoffmaterialien geformt werden und daß der Käfigabschnitt aus einem härteren Harz- oder Kunststoffmaterial als die Kugelpfanne geformt wird.
5. Rollführungsvorrichtung mit einem Wälzkörper-Abstandshalter nach einem der Ansprüche 1 bis 4.

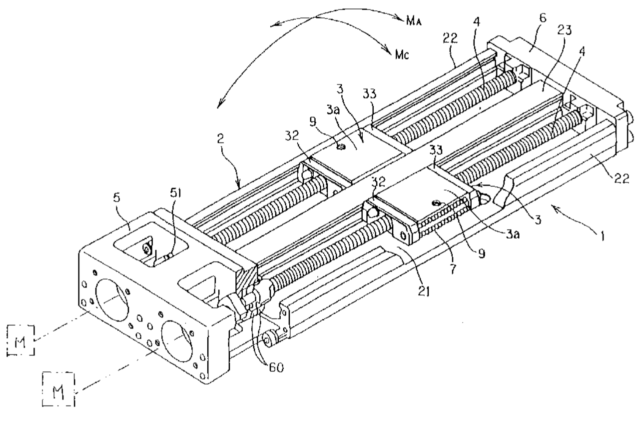
Die folgenden Angaben sind den vom Anmelder eingereichten Unterlagen entnommen

(54) Antriebsvorrichtung

(57) Eine Antriebsvorrichtung enthält einen Führungstisch (2) mit einem flachen Teil (21), senkrechten Seitenteilen (22), die sich parallel zueinander entlang den Seitenrändern des flachen Teils erstrecken, und mindestens einem Teilungsabschnitt (23), der an dem flachen Teil (21) in einem Bereich zwischen den rechtwinkligen Seitenabschnitten (21) ausgebildet ist, wobei er sich parallel zu diesen erstreckt. Bewegungstische (3, 3) sind in jeweils einen Raum zwischen einem der rechtwinkligen Seitenteile und dem Teilungsabschnitt (23) eingesetzt. Die Bewegungstische besitzen an ihren Seitenflächen Laufflächen für belastete Kugeln zur Bildung von Kugelumlaufkanälen entsprechend Laufflächen an dem Führungstisch (2). In den Kugelumlaufkanälen sind mehrere Kugeln angeordnet und zirkulieren in den Kanälen entsprechend der Relativbewegung zwischen dem Führungstisch (2) und den Bewegungstischen. Eine antreibende Einheit dient zum relativen Antreiben von Führungstisch und Bewegungstisch.



DE 101 15 943 A 1

Beschreibung

[0001] Die Erfindung betrifft eine Antriebsvorrichtung mit großer Breite und beispielsweise einer Vorschubspindel sowie einer Linearführungseinrichtung.

[0002] Bekannt ist eine Antriebsvorrichtung mit einem Aufbau, der eine Vorschubspindel als Antriebseinrichtung enthält, zum Beispiel einen Kugelumlauf-Stellantrieb, eine Gleitspindel oder dergleichen, und außerdem eine Linearführungseinrichtung aufweist. Eine solche Antriebseinrichtung besteht im wesentlichen aus einer Spindel, die auf ihrer Außenfläche mit einer spiralförmigen Nut ausgestattet ist, einer linearen Führungsschiene als Längs-Führungstisch oder Spurtisch parallel zu der Spindel, und einem als Bewegungselement dienenden Block, der an der Linearführungsschiene in deren Längsrichtung beweglich gelagert ist, wobei der bewegliche Block mit einem Mutterelement ausgestattet ist, welches in Gewindeeingriff mit der Spindel steht.

[0003] Üblicherweise ist an einer solchen Antriebsvorrichtung eine Werkzeugmaschine, beispielsweise ein Maschinentisch, gelagert, wobei dieses Maschinenteil in eine gewünschte Stellung gebracht und dort angehalten wird. Diese Positionssteuerung der Werkzeugmaschine erfolgt zum Beispiel dadurch, daß man die Drehbewegung der Spindel beim Betreiben eines Motors oder einer anderen Antriebseinrichtung steuert. Wie erwähnt, kann man eine solche Antriebsvorrichtung als Kompaktvorschubeinheit mit guter Montierbarkeit und Einstellbarkeit bezeichnen. Aus diesem Grund wurde eine solche Antriebsvorrichtung bisher für verschiedene Industrieroboter, Transportanlagen und dergleichen verwendet.

[0004] Wie beispielsweise in dem japanischen offengelegten Gebrauchsmuster HEI 2-12554 dargestellt ist, umfassen Antriebsvorrichtungen der oben genannten Art grundsätzlich zwei verschiedene Bautypen: den Sattel- oder Überspreizungstyp, bei dem ein einen Bodenteil und daran in Längsrichtung verlaufende Seitenteile aufweisender beweglicher Tisch eine Führungsschiene überspreizt und an dieser entlang bewegbar ist; und einen Nuteinsatztyp, bei dem ein bewegliches Element mit rechteckigem Querschnitt beweglich in eine nutförmige Ausnehmung eines Spurelements eingepaßt ist, wobei das Spurelement kastenförmigen Querschnitt hat und damit das bewegliche Element in dem Spurelement in dessen Längsrichtung beweglich ist.

[0005] Vergleicht man die beiden Bautypen miteinander bezüglich der gleichen Nenn-Last, so läßt sich eine Linearführungseinrichtung vom Nuteinsatztyp mit geringerer Bauhöhe fertigen als der Überspreizungstyp, er kann also kompakter bauen, wobei er entsprechend weniger Platz einnimmt. In dieser Hinsicht läßt sich sagen, daß der Nuteinsatztyp vom Aufbau her effizienter eingesetzt werden kann bei Robotern oder Transporteinheiten, deren Einsatz für beschränkte oder enge Räume vorgesehen ist.

[0006] Der Nuteinsatztyp (idly groove-fitting type) soll im folgenden anhand der **Fig.** 7 und 8 näher erläutert werden.

[0007] Ein Spur- oder Führungstisch **90** mit kastenförmigem Querschnitt und einer gewissen Längserstreckung setzt sich zusammen aus einem horizontalen flachen Abschnitt, der einen Bodenteil **90**a bildet, und einem Paar seitlicher Abschnitte, die von dem Bodenteil **90**a aufrecht abstehen, wie in den **Fig.** 7 und 8 zu sehen ist, wodurch zwischen den genannten Teilen eine Ausnehmung gebildet wird. Die Seitenabschnitte sind mit inneren Seitenflächen **91**, **91** ausgestattet, in denen zwei Reihen (eine obere und eine untere) Kugellaufnuten **92**, **92** so ausgeformt sind, daß sich die Nuten parallel zueinander in Längsrichtung erstrecken. Außerdem ist in dem in Breitenrichtung gesehen mittleren Abschnitt des kastenförmigen Führungstisches **90** eine Spindel **93** für den Kugelumlauf-Stellantrieb angeordnet, parallel zu den Kugellaufflächen **92**, **92**.

[0008] Ein Bewegungstisch **94** ist ein Bauteil mit einer Oberseite, auf der ein Tisch T oder dergleichen gelagert wird, um ein Werkzeugmaschinenteil oder ein anderes Bauelement zu transportieren, oder um andere Artikel auf dem Tisch T anzuordnen. Der Bewegungstisch **94** besitzt Rechteck-Querschnitt und ist mit einem Mutterabschnitt **95** ausgestattet, der mit der Kugelumlaufspindel **93** zusammenwirkt. Der Bewegungstisch **94** besitzt eine Breitenabmessung, die etwas geringer ist als die Innenabmessung der Ausnehmung des Führungstisches **90**, wie aus **Fig.** 8 ersichtlich ist.

[0009] Der Bewegungstisch **94** ist lose in der Ausnehmung (Nut) des Führungstisches **90** aufgenommen. Der Bewegungstisch **94** ist mit Seitenflächen versehen, in denen Kugellaufflächen **94**a, **94**a für belastete Kugeln derart ausgebildet sind, daß sich die Laufflächen gegenüber den Kugellaufflächen **92**, **92** in den Seitenflächen **91**, **91** des Führungstisches **90** befinden. Außerdem sind Kugelrücklaufkanäle, jeweils bestehend aus einem geradlinigen Durchgangsloch, in einem massiven Abschnitt des Bewegungstisches ausgebildet, wobei sich die Kanäle parallel zu den Laufflächen **94**a für belastete Kugeln erstrecken, wobei außerdem U-förmige Laufrichtungs-Änderungskanäle an dem Bewegungstisch an dessen Längsenden ausgebildet sind, die die Laufflächen **94**a für belastete Kugeln mit den Kugelrücklaufkanälen **94**b verbinden, wodurch jeweils ein Endlos-Kugelumlaufkanal gebildet wird, in welchem eine Anzahl von Kugeln **97** als Wälzelemente aufgenommen ist, die entlang dem Kanal abrollen.

[0010] Wenn im Betrieb die Kugelumlaufwelle **93** durch Antreiben seitens eines nicht gezeigten Servomotors gedreht wird, bewegt sich der Bewegungstisch **94** im Verein mit der Drehbewegung der Kugelumlaufspindel **93** und wird entlang dem Führungstisch **90** in dessen Längsrichtung geführt. Bei diesem Vorgang läßt sich die Bewegung des Bewegungstisches **94** ruckfrei aufgrund der Rollbewegungen der Stahlkugeln B durchführen, welche zwischen dem Mutterelement **95** und der Kugelumlaufspindel **93** angeordnet sind, während die Kugeln **97** sich zwischen dem Führungstisch **90** und dem Bewegungstisch **94** befinden. Eine über den Tisch T auf den Bewegungstisch **94** einwirkende Last eines Gegenstands, beispielsweise eines Maschinenwerkzeugteils, eines Tisches oder dergleichen, oder eines auf dem Tisch T befindlichen Transportguts, wirkt direkt auf eine Anzahl von Kugeln **97** ein, die sich abrollend zwischen den Kugellaufflächen **92**, **92** und den Kugellaufflächen **94**a, **94**a für belastete Kugeln befinden. Darüber hinaus sind die Kugellaufflächen **92**, die Kugellaufflächen **94**a für belastete Kugeln und die Kugeln **97** derart angeordnet, daß sie die Abmessungen der Lücken zwischen jeder der Kugellaufflächen **92** und jeder der Kugeln **97** sowie zwischen jeder der Laufflächen **94**a für belastete Kugeln und jeder der Kugeln **97** kleiner zu machen trachten, wodurch auf die Kugeln **97** eine Vorspannung ausgeübt wird.

[0011] Bei einer herkömmlichen Antriebsvorrichtung mit dem oben beschriebenen Aufbau ist allerdings der Bodenteil **90**a des Führungstisches **90** von beträchtlicher Breite, so daß er die Neigung hat, sich durch ein Lastmoment Mc (**Fig.** 8) zu verformen oder durchzubiegen, welches in Abrollrichtung auf den Bewegungstisch einwirkt, wodurch die beiden Seitenabschnitte mit den Innenflächen **91**, **91**, in denen die Kugelaufnuten ausgebildet sind, nach außen geöffnet werden. Dies verursacht im Ergebnis eine Situation, in der der enge Kontakt zwischen den Kugeln **97**, der Kugellauffläche **92** und der Kugellauffläche **94**a für belastete Kugeln aufgehoben oder gelockert wird und es zu der Schwierigkeit kommt, auf die Kugeln **97** eine ausreichend starke Vorspannung aufzubringen. Bei einer Bewegung des Bewegungstisches **94** kommt es dann zu einer Gier- oder Nickbewegung aufgrund der verringerten Vorspannung, demzufolge man kein glattes und ruckfreies lineares Vorrücken des bewegten Teils erwartet werden kann. Dies ist von Nachteil.

[0012] Um den oben angesprochenen Mangel zu beheben, gab es die Idee, mehrere derartige Antriebsvorrichtungen Seite an Seite parallel zueinander anzuordnen. Allerdings erfordert eine solche seitliche Parallelanordnung beträchtlichen Platz in Breitenrichtung und eignet sich nicht zur Unterbringung in einem eng begrenzten Raum. Darüber hinaus erfordert eine solche Parallelanordnung eine hochgenaue Einstellung der parallelen Fluchtung und Arbeitsposition. Um außerdem den Betriebswiderstand der Anordnung minimal zu machen, ist beträchtlicher Zeit- und Arbeitsaufwand für eine Bedienungsperson erforderlich, wobei außerdem die Fertigungskosten für mehrere Antriebsvorrichtungen beträchtlich hoch sind.

[0013] Ziel der Erfindung ist es, die in dem oben erläuterten Stand der Technik anzutreffenden Unzulänglichkeiten oder Nachteile zu beheben und eine Antriebsvorrichtung mit breitem Aufbau zu schaffen, bei der es weniger Änderung der Vorspannung zwischen einem Wälzelement und einer Wälzelement-Lauffläche auch dann gibt, wenn eine Last, insbesondere ein Lastmoment in der Abrollrichtung relativ groß ist. Dabei sollen die Abmessungen in Breitenrichtung der Antriebsvorrichtung gering gehalten werden, ferner soll der Zusammenbau einfach und problemlos bei verringerten Fertigungskosten geschehen können.

[0014] Erreicht werden diese sowie weitere Ziele erfindungsgemäß durch eine Antriebsvorrichtung, insbesondere eine Antriebsvorrichtung mit beträchtlicher Breite, welche die Merkmale des Anspruchs 1 aufweist.

[0015] Vorteilhafte Weiterbildungen und Ausgestaltungen der Erfindung sind in den abhängigen Ansprüchen angegeben.

[0016] Gemäß diesen Weiterbildungen ist jeder der Bewegungstische mit Lagerteilen ausgestattet, um einen zu transportierenden Gegenstand zu lagern, wobei die Lagerteile an den beweglichen Tischen an einer Stelle ausgebildet sind, die in Bewegungsrichtung der Bewegungstische im wesentlichen zentral ist, wobei sie gleichzeitig in Richtung der Seitenabschnitte des Führungstisches versetzt sind.

[0017] Der Führungstisch ist eine Außenschiene, die Bewegungstische werden durch innere Blöcke gebildet.

[0018] Die Antriebsmittel umfassen ein Vorschubgewinde, eine Vorschubgewindewelle und eine Motoreinrichtung, die mit der Vorschubspindel betrieblich verbunden ist. Werden Kugeln als Wälz- oder Rollelemente verwendet, so ist das Vorschubgewinde vorzugsweise ein Kugelumlaufgewinde für jeden der Bewegungstische, wobei die Vorschubwelle eine Kugelumlaufspindel ist und mehrere Kugelumlaufspindeln synchron von mindestens einem Motor angetrieben werden.

[0019] Der flache Abschnitt, die dazu rechtwinkligen Seitenabschnitte und der Teilungsabschnitt des Führungstisches sind einstückig miteinander ausgebildet. Der Führungs- oder Spurtisch und die beweglichen Tische sind durch Zusammenbau als Linearführungsanordnung ausgebildet.

[0020] Da bei dem Aufbau mit den besonderen Merkmalen der vorliegenden Erindung der Teilungsabschnitt des Führungstisches vorhanden ist, kann sich der flache Abschnitt oder Bodenabschnitt des Führungstisches auch dann nicht durchbiegen, wenn er beträchtliche Abmessungen in Breitenrichtung besitzt. Aus diesem Grund läßt sich die Gegenmoment-Fähigkeit verbessern, wobei sich die Seitenabschnitte des Führungstisches nicht nach außen öffnen. Dementsprechend ändert sich die auf die Wälzelemente und die Wälzelement-Laufflächen aufgebrachte Vorspannung praktisch nicht, wodurch ein glattes und ruckfreies Bewegen des Bewegungstisches garantiert wird. Da es außerdem nicht notwendig ist, eine Mehrzahl von Führungsvorrichtungen Seite an Seite anzuordnen, läßt sich der Aufnahmeraum in Breitenrichtung reduzieren, außerdem können Zusammenbau in kürzerer Zeit und mit weniger Arbeitsaufwand und dementsprechend mit weniger Kosten durchgeführt werden.

[0021] Da sich ferner die Lagerabschnitte (Befestigungsbolzenlöcher) an dem Bewegungstisch an einer Stelle befinden, die im wesentlichen zentral an dem Bewegungstisch entlang dessen Bewegungsrichtung liegt, dabei aber in Richtung der Seitenabschnitte des Führungstisches versetzt ist, wird die Belastung durch den zu transportierenden Gegenstand gleichmäßig auf die jeweiligen rechtwinkligen Seitenabschnitte und den Zwischenabschnitt verteilt, demzufolge die Gegenmoment-Fähigkeiten für die Wälzelement-Laufflächen im wesentlichen gleich groß gehalten werden können, was eine ausgewogene Starrheit und Steifigkeit schafft. Der Bewegungstisch kann dementsprechend glatter bewegt werden. Die Ausbildung der Befestigungsbolzenlöcher als Lagerabschnitte ermöglicht ein einfaches und problemloses Anbringen und Lagern des zu transportierenden Gegenstands und macht die gesamte Struktur des Bewegungstisches einfach und kompakt.

[0022] Im folgenden werden Ausführungsbeispiele der Erfindung anhand der Zeichnung näher erläutert. Es zeigen:

[0023] **Fig.** 1 eine teilweise geschnittene perspektivische Ansicht einer Antriebsvorrichtung mit breitem Aufbau (großer Breitenabmessung) gemäß einer Ausführungsform der Erfindung;

[0024] **Fig.** 2 eine Draufsicht auf einen wesentlichen Teil der Antriebsvorrichtung nach **Fig.** 1;

[0025] **Fig.** 3 eine Schnittansicht entlang der Linie III-III in **Fig.** 2;

[0026] **Fig.** 4 eine perspektivische Ansicht eines wesentlichen Teils der Antriebsvorrichtung nach **Fig.** 1 in vergrößertem Maßstab;

[0027] **Fig.** 5 eine Draufsicht auf eine Antriebsvorrichtung gemäß einer weiteren Ausführungsform der Erfindung;

[0028] **Fig.** 6 ebenfalls eine Draufsicht auf eine Antriebsvorrichtung gemäß einer weiteren Ausführungsform der Erfindung;

[0029] **Fig.** 7 eine perspektivische Ansicht eines wesentlichen Teils einer Antriebsvorrichtung mit herkömmlichem Aufbau; und

[0030] **Fig.** 8 eine Schnittansicht der Antriebsvorrichtung nach **Fig.** 7.

[0031] Anhand der **Fig.** 1 bis 4 soll im folgenden eine erste bevorzugte Ausführungsform einer erfindungsgemäßen Antriebsvorrichtung erläutert werden.

[0032] Die Antriebsvorrichtung **1** gemäß der Erfindung ist eine solche mit besonders großen Abmessungen in Breitenrichtung (breiter lateraler Aufbau) und wird hier einfach als "Antriebsvorrichtung" bezeichnet. Nach **Fig.** 1 enthält die Antriebseinrichtung **1** eine Außenschiene **2** als Führungstisch mit einer gewissen Längserstreckung, zwei Innenblöcke **3**, **3** als Bewegungstisch (oder Bewegungstische), der sich entlang der Außenschiene **2** geführt verfahren läßt, Antriebsmittel in Form eines Kugelumlaufantriebs mit Kugelumlaufspindeln **4**, **4** zum Aufbringen einer Antriebskraft zur Relativbewegung zwischen der Außenschiene **2** und den Innenblöcken **3**, **3**, und Gehäuse **5** und **6**, die das vordere bzw. hintere Ende (die Längsenden) der Kugelumlaufspindeln **4**, **4** drehbar lagern.

[0033] Die Außenschiene **2** besteht gemäß **Fig.** 2 und 3 aus einem flachen Bodenteil **21** mit flacher Oberfläche, dazu rechtwinkligen Seitenteilen **22**, **22**, die sich parallel zueinander und an den Seiten des flachen Bodenteils **21** erstrecken, und einem Teilungsabschnitt **23**, der von dem flachen Bodenteil **21** ähnlich wie die Seitenteile **22**, **22** hochsteht und sich parallel zu diesen Seitenteilen **22**, **22** erstreckt. Bei diesem Aufbau wird die Außenschiene **2** in einen dargestellten Zustand (vertikal installierten Zustand) durch zwei Ausnehmungen mit oberen Öffnungen gebildet, untereinander abgetrennt durch den Teilungsabschnitt **23**, der sich in Längsrichtung der Ausnehmungen erstreckt. Der Bodenteil **21** der Außenschiene **2** enthält außerdem eine Mehrzahl von Bolzenlöchern **2**b, **2**b zum Befestigen der Antriebsvorrichtung als eine bauliche Komponente beispielsweise einer Werkzeugmaschine mit Hilfe von Bolzen oder dergleichen.

[0034] Bei einer bevorzugten Ausführungsform sind der flache Bodenteil **21**, die Seitenteile **22**, **22** und der Teilungsabschnitt **23** einstückig miteinander durch beispielsweise Spritzgießen gebildet. Die einstückige Ausbildung steigert die Festigkeit und Steifigkeit der gesamten Außenschiene **2** und verringert Arbeitsprozesse, was folglich bequem und wirtschaftlich ist. Allerdings können diese Teile auch unabhängig voneinander hergestellt und dann mit Hilfe von Bolzen und Muttern oder dergleichen zusammengebaut werden.

[0035] Beide senkrechten Seitenteile **22**, **22** besitzen Innenflächen **22**a, **22**a, an denen jeweils zwei vertikale Reihen von Kugellaufflächen (Wälzelement-Laufflächen) **24**a, **24**b ausgebildet sind. Es sind also insgesamt vier Kugellaufflächen **24**a, **24**a, **24**b und **24**b so angeordnet, daß sie sich in Längsrichtung der Innenflächen erstrecken. Außerdem sind an jeder der Seitenflächen **23**a, **23**a des Teilungsabschnitts **23** vertikal beabstandet zwei Reihen von Kugellaufflächen (Wälzelement-Laufflächen) **25**a, **25**b ausgebildet, die sich in Längsrichtung des Teilungsabschnitts erstrecken.

[0036] Die Innenblöcke **3**, **3** sind in die beiden Ausnehmungen **2**a, **2**a der Außenschiene **2** aufgenommen und werden von dieser über eine Anzahl von Kugeln **7**, **7**, . . . **7**, die Wälzelemente darstellen, gehaltert. Die Innenblöcke **3**, **3** besitzen Seitenflächen, an denen insgesamt acht Reihen von Laufflächen für belastete Kugeln (Laufflächen für belastete Wälzelemente) **34**a, **34**a, **34**b und **34**b derart ausgebildet ist, daß diese Laufflächen den acht Reihen von Kugellaufflächen **24**a, **24**a, **24**b, **24**b, **25**a, **25**a, **25**b bzw. **25**b der Außenschiene **2** entsprechen, das heißt im Zusammengebauten Zustand diesen Kugellaufflächen gegenüberstehen, wobei eine Reihe von Kugeln **7**, **7**, . . . **7** zwischen diesen Kugellaufflächen und Laufflächen für belastete Kugeln abrollbar angeordnet ist.

[0037] Jeder der Innenblöcke **3** ist an seinem mittleren Bereich mit einem Mutterabschnitt **31** ausgestattet, mit welchem die Spindelwelle **4** in Gewindeeingriff steht, wobei der Mutterabschnitt **31** sich zusammensetzt aus einem Kugelumlaufloch **31**a, welches direkt in den Innenblock **3** eingeformt ist. Das Kugelumlaufloch **31**a ist gemäß **Fig.** 1 in einem Bereich auf einer Linie ausgebildet, welche Mittellinien von Verbindungen zwischen oberen und unteren zwei Reihen von Kügellaufflächen **34**a, **34**b, **35**a und **35**b auf den beiden Seitenflächen des Innenblocks **3** verbindet. Außerdem kann der Mutterabschnitt **31** unabhängig von dem Innenblock **3** als einzelnes Element ausgebildet sein.

[0038] Darüber hinaus sind die Innenblöcke **3** mit Kugelrücklaufkanälen **36**c, **36**c, **36**d, **36**d, **37**c, **37**c, **37**d und **37**d zum Zurückführen der Kugeln **7** ausgestattet, welche den belasteten Kugellaufbereich in Abschnitten zwischen den jeweiligen Seitenflächen der Innenblöcke **3**, **3** und den Kugelumlauflöchern **31**a, **31**a passiert haben, wobei die Kugelrücklaufkanäle den Laufflächen für belastete Kugeln, **34**a, **34**a, **34**b, **34**b, **35**a, **35**a, **35b** bzw. **35b** entsprechen. Bei der dargestellten Ausführungsform sind diese Kugelrücklaufkanäle **36**c, **36**c, **36**d, **36**d, **37**c, **37**c, **37**d, **37**d derart angelegt, daß sie auf horizontalen Linien liegen, die durch die Mitten der jeweiligen Kugellaufflächen der Außenschiene **2** und der Kugellaufflächen für belastete Kugeln der Innenblöcke **3**, **3** gehen. Außerdem ist auf sämtliche Kugeln **7**, **7**, . . . **7** eine Vorspannung aufgebracht, wobei diese Vorspannung dadurch entsteht, daß die Abmessung der Lücken zwischen den jeweiligen Kugellaufflächen **24**a... und jeder der Kugeln **7** sowie zwischen jeder der Laufflächen für belastete Kugeln, 34a . . . und jeder der Kugeln **7** mit einem Minderbetrag (–) gefertigt ist.

[0039] Wie außerdem in den **Fig.** 1 bis 3 zu sehen ist, sind die Innenblöcke **3**, **3** mit Schraubenlöchern (Lagerabschnitten) **9**, **9** zur Anbringung eines zu transportierenden Gegenstands auf den Oberseiten der Innenblöcke **3**, **3** ausgestattet. Die Gewindelöcher **9**, **9** sind in Bereiche an den Seiten der Innenflächen **22**a, **22**a der rechtwinkligen Seitenteile **22**, **22** derart gebohrt, daß sie gegenüber der Stelle der Kugelrücklaufkanäle **36**c, **36**c, **36**d, **36**d, **37**c, **37**c, **37**d und **37**d entfernt sind.

[0040] Die Kugelumlauflöcher **31**a, die die Mittelbereiche der Innenblöcke **3**, **3** durchsetzen, sind auf der Hälfte ihrer Erstreckung (Zonen) in der in die Innenblöcke **3**, **3** eindringenden Richtung mit Gewindenuten ausgestattet, wie dies in **Fig.** 4 dargestellt ist, wobei für die Kugelumlauflöcher **31**a jeweils ein Rücklaufkanal **41** vorgesehen ist, so daß insgesamt durch diese Teile ein Kugelumlaufkanal gebildet wird. Außerdem erhalten auch die Kugeln B zwischen der Kugelumlaufspindel **4** und dem Kugelumlaufloch **31**a eine Vorspannung.

[0041] Wie in **Fig.** 1 und **Fig.** 2 zu sehen ist, sind die Innenblöcke **3**, **3** an ihren längsseitigen Enden mit Stirnplatten **32**, **33** ausgestattet, die vorzugsweise aus Kunststoffmaterial bestehen und jeweils etwa Rechteckform besitzen, etwa mit dem gleichen Grundriß wie der Innenblockkörper **3**a, der aus metallischem Material besteht. Die Stirnplatten **32** und **33** sind an den Innenblockkörpern **3**a, **3**a beispielsweise mittels Schrauben befestigt.

[0042] Die Stirnplatten **32** und **33** sind an ihren Lagerflächen bezüglich der Innenblockkörper **3**a, **3**a mit Laufrichtungs-Änderungskanälen **32**a, **32**a, **32**b, **32**b, **33**a, **33**a, **33**b und **33**b ausgestattet, um die Kugeln **7** aus den Belastungsbereichen zwischen den Innenblöcken **3**, **3** und der Außenschiene **2** aufzunehmen und sie in die Kugelrücklaufkanäle **36**c, **36**d, **37**c, **37**d und dann wieder in die belasteten Bereiche zu führen. Das heißt: an jeweils einer Stirnplatte sind vier Laufrichtungs-Änderungskanäle ausgebildet. Dementsprechend setzen sich die Kugelumlaufkanäle jeweils zusammen aus den Laufrichtungs-Änderungskanälen, den Kugelrücklaufkanälen und den Laufkanälen für belastete Kugeln. Die Kugeln **7**, **7**, ... **7** sind in den Kugelumlaufkanälen derart angeordnet und aufgenommen, daß sie entsprechend der Relativbewegung zwischen der Außenschiene **2** und den Innenblöcken **3**, **3** zirkulieren. Außerdem befinden sich offensichtlich die Laufflächen für die belasteten Kugeln auf den Außenseiten der jeweiligen Innenblöcke **3**, **3**.

[0043] Wie in **Fig.** 1 gezeigt ist, ist jede der Kugelumlaufspindeln **4**, **4** in das Kugelumlaufloch **31**a des jeweiligen Innenblocks **3**, **3** eingesetzt, ist mit einem Ende über einen nicht gezeigten Lagerteil im Gehäuse **6** an einem Ende der Außenschiene **2**, und ist mit dem anderen Ende ebenfalls drehbar durch ein Lagerteil **60** des Gehäuses **5** am anderen Ende der Außenschiene **2** gelagert. Diese Kugelumlaufspindeln **4**, **4** sind betrieblich mit Wellen von zwei nicht gezeigten Motoren gekoppelt, beispielsweise über Verbindungselemente.

[0044] Die Antriebsvorrichtung breiter Struktur gemäß obiger Beschreibung arbeitet folgendermaßen:

[0045] Wenn die erwähnten beiden Motoren synchron angetrieben werden, werden die Kugelumlaufspindeln **4**, **4** der Antriebsvorrichtung **1** gemeinsam gedreht, und diese Drehbewegungen werden über die Mutterabschnitte **31**, **31** auf die Innenblöcke **3**, **3** übertragen, die hierdurch entlang der Außenschiene **2** in dieselbe Richtung hin- und herbewegt werden.

[0046] Da bei diesem Vorgang die Schraubenlöcher oder Gewindelöcher, die zur Befestigung des zu transportierenden Gegenstands dienen, an Stellen ausgebildet sind, die zu den jeweiligen beiden Seiten der Außenschiene **2** versetzt sind und außerdem bezüglich der Bewegungsrichtung der Innenblöcke **3**, **3** mittig angeordnet sind, wird die durch den Gegenstand bedingte Last im wesentlichen gleichförmig auf beide rechtwinklige Seitenteile 22, 22 und den Teilungsabschnitt **23** der Außenschiene **2** verteilt. Aus diesem Grund lassen sich die Gegenmoment-Lastaufnahmefähigkeiten der jeweiligen Kugellaufflächen ausgleichen, demzufolge die Kugellaufflächen in seitlicher Richtung bezüglich der Last starr ausbalanciert sind. Damit sind die Innenblöcke **3**, **3** ruckfrei linear beweglich.

[0047] Da bei der beschriebenen Ausführungsform der Teilungsabschnitt **23** an der Außenschiene **2** ausgebildet ist, um die beiden Innenblöcke **3**, **3**, die Seite an Seite angeordnet sind, voneinander zu trennen oder aufzuteilen, ist es möglich, den horizontalen Teil **21** (den flachen Bodenteil) an einer Durchbiegung oder Auslenkung auch dann zu hindern, wenn die Außenschiene **2** eine sehr breite Struktur oder Abmessung besitzt, wodurch die Gegenmoment-Aufnahmefähigkeit verbessert und verhindert wird, daß die Seitenteile **22**, **22** nach außen geöffnet werden. Dies ist im Betrieb von Vorteil und zweckdienlich.

[0048] Aufgrund der obigen Umstände wird eine auf die Kugeln **7** und die Kugellaufflächen aufgebrachte Vorspannung nicht oder praktisch nicht geändert, demzufolge Fluktuationen der Innenblöcke **3**, **3** wirksam verhindert und mithin eine ruckfreie und glatte Bewegung der Innenblöcke **3**, **3** garantiert wird.

[0049] Das Verhindern des Biegens oder Durchbiegens des horizontalen Teils **21** der Außenschiene **2** durch die genannte Plazierung des Teilungsabschnitts **23** wird im folgenden näher erläutert.

[0050] Zunächst: bezüglich des Lastmoments MA in Nickrichtung gemäß **Fig.** 1 ist anzumerken, daß die Außenschiene **2** eine Schale darstellt, wobei der Trennabschnitt **23** die Funktion eines Kiels hat und dementsprechend eine äußerst hohe Steifigkeit für die Außenschiene **2** in dieser Belastungsrichtung gewährleisten kann.

[0051] Weiterhin: was die Verformung der Außenschiene **2** entsprechend einer pferdesattelähnlichen Aufspreizung angeht, so ist hier das Poisson-Verhältnis maßgeblich, demzufolge der Teilungsabschnitt **23** eine Durchbiegung der Außenschiene **2** bezüglich des Lastmoments MA in Nickrichtung unterdrücken kann, dementsprechend auch die Durchbiegung bezüglich des Lastmoments MC in Rollrichtung gemäß **Fig.** 1 verhindert werden kann.

[0052] Die Verbesserung hinsichtlich des Belastungs-Gegenmoments durch die Plazierung des Teilungsabschnitts **23** führt zu der Situation, daß die Antriebsvorrichtung ausreichende Festigkeit und Steifigkeit auch dann haben kann, wenn die Höhe der Außenschiene **2**, das heißt die Höhe der Gesamtstruktur der Antriebsvorrichtung, reduziert wird.

[0053] Um die Gegenmoment-Fähigkeit gegenüber Lastmomenten weiter zu verbessern, kann es zusätzlich zu den obigen Merkmalen wirksam sein, die Dicke des flachen Bodenteils **21** und der rechtwinkligen Seitenteile **22**, **22** der Außenschiene **2** zu verstärken und die Dicke der Querteile des flachen Bodenteils **21** und der rechtwinkligen Seitenteile **22**, **22** der Außenschiene **2** zu erhöhen.

[0054] Außerdem ist es gemäß der Ausführungsform der vorliegenden Erfindung nicht notwendig, mehrere Antriebsvorrichtungen Seite an Seite wie bei dem herkömmlichen Vorschlag anzuordnen, demzufolge der Unterbringungsraum in Breitenrichtung reduziert wird und die Antriebsvorrichtung einfach eingerichtet und eingestellt werden kann, demzufolge sich Arbeitsaufwand und Arbeitszeit für eine Bedienungsperson ebenso wie die Fertigungskosten verringern.

[0055] Bei einer modifizierten Ausführungsform kann eine Mehrzahl von Innenblöcken größer als zwei Seite an Seite parallel zueinander angeordnet sein. Bei einer solchen Ausgestaltung erhöht sich entsprechend die Anzahl der Teilungsabschnitte **23**. Beim dargestellten Ausführungsbeispiel befindet sich zwar der Teilungsabschnitt **23** zwischen einander benachbarten zwei inneren Blöcken **3**, **3**, die jeweils in einem von beiden Vertiefungen **2**a aufgenommen sind, alternativ können aber zwei oder mehr als zwei Innenblöcke **3**, **3** in jeweils einer Ausnehmung **2**a der Außenschiene **2** aufgenommen sein. Bei der dargestellten Ausführungsform sind zwar die Gewindelöcher in den Innenblöcken als Halteabschnitte an Stellen ausgebildet, die auf beiden Seiten der Außenschiene **2** versetzt sind; alternativ können die Innenblöcke aber auch mit dem zu transportierenden Gegenstand gekoppelt sein, wobei die Innenblöcke **3**, **3** dann als Bewegungstisch fungieren.

[0056] Bei der dargestellten Ausführungsform sind zwei Motoren an einer Stirnseite der Außenschiene **2** angeordnet. Statt dessen können aber auch zwei Motoren M, M an den beiden Enden der Außenschiene angeordnet sein, wie dies in **Fig.** 5 gezeigt ist. Bei dieser Anordnung werden zwei Motoren M, M synchron betrieben, so daß eine hohe Schubkraft erzielbar ist. Natürlich ist es auch möglich, diese beiden Motoren M, M unabhängig ohne synchronen Betrieb zu betreiben.

[0057] Außerdem kann entgegen der Ausführungsform nach **Fig.** 5, wo zwei Motoren endseitig an der Außenschiene **2** vorgesehen sind, ein Antrieb der Kugelumlaufspindeln mit Hilfe eines einzelnen Motors erfolgen, wobei **Fig.** 6 eine derartige Ausgestaltung zeigt.

[0058] Nach **Fig.** 6 ist eine Ausgangswelle (Antriebswelle) eines Motors M betrieblich mit einer der beiden Kugelumlaufspindeln **4**, **4** über eine Kupplung verbunden. Ein Antriebszahnrad **81** auf dieser Ausgangswelle kämmt mit einem angetriebenen Zahnrad **82**, welches mit der anderen Kugelumlaufspindel **4**, **4** gekoppelt ist, über ein Zwischenzahnrad **83**. Wenn bei diesem Aufbau der Motor M angetrieben wird, drehen sich die beiden Kugelumlaufspindeln **4**, **4** synchron und gleichsinnig, um die beiden Innenblöcke **3**, **3** synchron zu bewegen.

[0059] Bei der in **Fig.** 6 gezeigten Ausgestaltung kann das Antriebszahnrad **81** direkt mit dem angetriebenen Zahnrad **82** ohne Zwischenrad **83** kämmen, wobei dann von einer rechtsgängigen Spindel und einer linksgängigen Spindel Gebrauch gemacht wird, um die beiden Kugelumlaufspindeln **4**, **4** zu bilden, während bei Verwendung des Zwischenrads **83** gleichsinnige Kugelumlaufspindeln **4**, **4** benutzt werden können.

[0060] Außerdem kann man als Vorschubspindel anstelle der Kugelumlaufspindel der beschriebenen Ausführungsform eine Gleitspindel verwenden, und man kann außerdem anstelle der Kugeln **7** und B bei der beschriebenen Ausführungsform andere Wälzkörper, beispielsweise Rollen, verwenden.

[0061] Bei der dargestellten Ausführungsform wird zwar die Vorschubspindel als Antriebseinrichtung zur Ausführung der Relativbewegung zwischen der Außenschiene **2** und den Innenblöcken **3**, **3** verwendet, allerdings kann auch eine andere Antriebseinrichtung verwendet werden, so zum Beispiel ein Linearmotor. Bei einem Linearmotor kann ein zylindrischer Magnet als Stator und eine Ringspule an dem Magneten als Bewegungselement eingesetzt werden.

[0062] Gemäß obiger Beschreibung wurde die Linearbewegung zwischen der Außenschiene **2** und den Innenblökken **3**, **3** erwähnt, allerdings ist auch ein Aufbau denkbar, bei dem die Außenschiene **2** und die Innenblöcke **3**, **3** entlang einer gekrümmten Bahn relativ zueinander beweglich sind.

Patentansprüche

1. Antriebsvorrichtung, umfassend:
einen Führungstisch (**2**) mit einem flachen Teil (**21**), sich entlang der beiden Seitenränder des flachen Teils (**21**) in dessen Längsrichtung rechtwinklig erstreckenden, zueinander parallel verlaufenden Seitenteilen (**22**, **22**) und mindestens einem Teilungsabschnitt (**23**), der an dem flachen Teil (**21**) in einem Bereich zwischen den rechtwinkligen Seitenteilen (**22**, **22**) so ausgebildet ist, daß er sich parallel zu den Seitenteilen erstreckt, wobei die rechtwinkligen Seitenteile (**22**, **22**) auf ihren Innenseiten Wälzelement-Laufflächen (**24**a, **24**b, **25**a, **25**b) aufweisen, die sich in Längsrichtung der Seitenteile erstrecken, und der Teilungsabschnitt (**23**) auf beiden Seitenflächen Wälzelement-Laufflächen für belastete Wälzelemente (**34**a, **34**b, **35**a, **35**b) aufweist, die sich in Längsrichtung des Teilungsabschnitts erstrekken;
mehrere Bewegungstische (**3**, **3**), die jeweils in einen Raum eingesetzt sind, welcher zwischen einem der rechtwinkligen Seitenteile (**22**, **22**) und dem Teilungsabschnitt (**23**) oder zwischen mehreren Teilungsabschnitten (**23**) definiert ist, wobei die Bewegungstische (**3**, **3**) jeweils äußere Seitenflächen aufweisen, in denen Wälzelement-Laufflächen für belastete Wälzelemente (**34**a, **34**b, **35**a, **35**b) gebildet sind, wodurch Wälzelement-Umlaufkanäle gebildet werden, welche den Wälzelement-Laufflächen (**24**a, **24**b, **25**a, **25**b) des Führungstisches (**2**) entsprechen;
eine Anzahl von Wälzelementen (**7**), die in den Wälzelement-Umlaufkanälen beweglich angeordnet sind, um in diesen entsprechend der Relativbewegung zwischen dem Führungstisch (**2**) und den beweglichen Tischen (**3**, **3**) zu zirkulieren; und
Antriebsmittel zum Antreiben des Führungstisches (**2**) und/ oder des Bewegungstisches (**3**, **3**), um eine Relativbewegung zwischen ihnen hervorzurufen.
2. Vorrichtung nach Anspruch 1, bei der jeder der Bewegungstische (**3**, **3**) mit Lagerabschnitten (**9**, **9**) ausgestattet ist, um einen zu transportierenden Gegenstand zu lagern, wobei die Lagerabschnitte (**9**, **9**) an den beweglichen Tischen (**3**, **3**) an einer Stelle ausgebildet sind, die sich entlang der Bewegungsrichtung der beweglichen Tische (**3**, **3**) etwa in der Mitte der Tische befindet, während sie in Richtung der Seitenabschnitte des Führungstisches (**2**) versetzt sind.
3. Vorrichtung nach Anspruch 2, bei der die Lagerabschnitte (**9**, **9**) Gewindelöcher sind, die in den Bewegungstischen (**3**, **3**) ausgebildet sind.
4. Vorrichtung nach einem der Ansprüche 1 bis 3, bei der der Führungstisch (**2**) eine Außenschiene ist und die Bewegungstische (**3**, **3**) Innenblöcke sind.
5. Vorrichtung nach einem der Ansprüche 1 bis 4, bei der die Antriebsmittel ein Vorschubgewinde, eine Gewindespindelwelle (**4**, **4**) und eine Motoreinrichtung, die betrieblich mit der Gewindespindelwelle (**4**, **4**) gekoppelt ist, aufweisen.
6. Vorrichtung nach Anspruch 5, bei der die Wälzelemente (B) Kugeln sind, das Vorschubgewinde ein Kugelumlaufgewinde für jeden Bewegungstisch (**3**, **3**) ist, und die Gewindespindelwelle eine Kugelumlaufspindel für jedes Kugelumlaufgewinde ist, wobei mehrere Kugelumlaufspindeln synchron von mindestens einem Motor angetrieben werden.
7. Vorrichtung nach einem der Ansprüche 1 bis 6, bei der der flache Teil (**21**), die senkrechten Seitenteile (**22**, **22**) und der Teilungsabschnitt (**23**) des Führungstisches (**2**) einstückig miteinander ausgebildet sind.
8. Vorrichtung nach einem der Ansprüche 1 bis 7, bei der der Führungstisch (**2**) und die Bewegungstische (**3**, **3**) in zusammengebautem Zustand als Linearführungsvorrichtung ausgebildet sind.

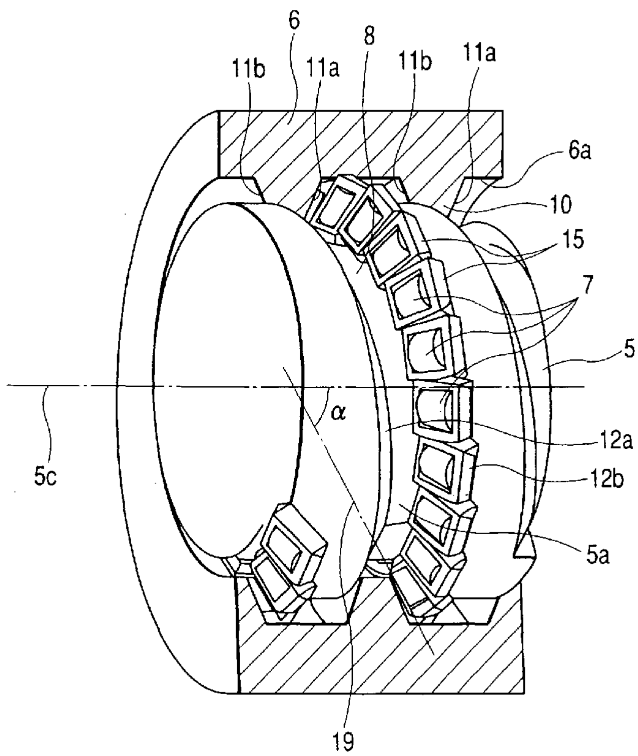
In einer linearen Bahn kommen die linearen Führungsbereiche (16a und 17a) jeweils in Kontakt mit benachbarten Walzenkäfigen (15). In einer gekrümmten Bahn kommen jeweils die gekrümmten Führungsbereiche (16b und 17b) in Kontakt mit benachbarten Walzenkäfigen (15).



DE 101 13 510 A 1

Beschreibung

HINTERGRUND DER ERFINDUNG

1. Gebiet der Erfindung

[0001] Die vorliegenden Erfindung bezieht sich auf einen Walzenkäfig, der in einer direkt wirkenden Führungseinrichtung, einer Walzenschraube oder ähnlichem verwendet wird, und bei dem eine Walze, die in einem umlaufenden Weg abwälzt, so gehalten wird, dass sie drehbar/verschiebbar ist.

2. Beschreibung des Stands der Technik

[0002] Eine Walzenschraube, die Walzen zwischen einer Schraubenwelle und einem Mutterelement zwischengeschaltet hat, ist bekannt. Wenn die Schraubenwelle relativ zu dem Mutterelement gedreht wird, macht das Mutterelement eine Hin- und Herbewegung in einer Richtung der Achse der Schraubenwelle. Die Walzen machen eine Wälzbewegung, so dass sie um den äußeren Umfang einer Schraubennut zwischen der Schraubenwelle und dem Mutterelement laufen. Somit laufen die Walzen in einem Walzenumlaufweg um. Eine helixförmige Walzenabwälznut ist in der Schraubenwelle geformt. Der Walzenumlaufweg, der eine helixförmige Lastabwälznut entsprechend der Walzen Abwälznut enthält, ist in dem Mutterelement geformt. In der Walzenschraube kann die Vielzahl von Walzen in dem Walzenumlaufweg so angeordnet sein, dass sie parallel zueinander sind, damit die Achsen von benachbarten Walzen näherungsweise parallel zueinander gehalten werden, oder die Vielzahl von Walzen kann in dem Walzenumlaufweg so angeordnet sein, dass die Walzen einander kreuzen, dass sich die Achsen von benachbarten Walzen schneiden.

[0003] Im allgemeinen machen im Fall einer Walzenschraube der Voll-Walzenart, bei der nur Walzen in dem Walzenumlaufweg angeordnet sind, die jeweiligen Walzen keine konsistente Bewegung, so dass jede der Walzen in einer Ebene nach unten fällt, die die Achse der Walze enthält und die Richtung der Bewegung der Walze um ein Festklemmen zu bewirken. Somit können sich die Walzen nicht bewegen, während sie in dem Walzenumlaufweg angeordnet sind. Obwohl es sich nicht auf eine Walzenschraube bezieht, ist ein gürtelartiger Kugelkäfig zum drehbar/verschiebbar Halten einer Vielzahl von Kugeln einer Kugelschraube bekannt, um einen geordneten Umlauf der Kugeln zu ermöglichen (beispielsweise aus der JP-A-11-223258). Der Kugelkäfig hält die Kugeln in der Form einer linearen Kette, so dass benachbarte Kugeln der Vorderseite und Rückseite sich glatt bewegen können.

[0004] Andererseits ist ein Käfig zum Halten von korrespondierenden Walzen, die in einem Umlaufweg einer direkt wirkenden Führungseinrichtung angeordnet und aufgenommen sind, bekannt (siehe JP-A-60-205013). **Fig.** 17 zeigt solche Käfige, die in dem Walzenumlaufweg der direkt wirkenden Führungseinrichtung umlaufen. Eine Vielzahl von Walzen **1** ist kreuzangeordnet in dem Walzenführungsweg **2**, so dass die Achsen von benachbarten Walzen **1** einander schneiden. Die Richtung der Walzen **1** wird zweidimensional zwischen einem linearen Lastdurchgang **2**a und einem U-förmigen Richtungsänderungsdurchgang **2**b verändert. **Fig.** 18 ist eine Vorderansicht eins Käfigs **3** mit einer Walze **1**, gesehen in der Bewegungsrichtung davon. **Fig.** 19 ist eine Querschnittsansicht entlang der Linie A-A aus **Fig.** 18. Aufgrund der kreuzenden Anordnung der Walzen **1** ist der Walzenumlaufweg **2** im wesentlichen wie ein Rechteck im Querschnitt geformt. Die Käfige **3** halten die Walzen **1** in Behälterlöchern **3**a der Käfige **3** drehbar/verschiebbar und individuell und entsprechend, wobei die äußeren Umfänge **1**a der Walzen **1** teilweise leicht freigelegt sind. Die Dicke des Käfigs **3** (die radiale Dicke der Walzen) ist näherungsweise gleich derjenigen der Walze **1** gesetzt. Wie es in den Zeichnungen gezeigt ist, bildet die Form des Käfigs **3**, die von der Vorderseite in der Richtung der Bewegung zu sehen ist, ein Rechteck, das näherungsweise gleich der Querschnittsform des Walzenumlaufwegs **2** ist, so dass die Walze **1** durch den Käfig **3** geführt werden kann. Wie es in **Fig.** 17 gezeigt ist, sind zwei Endoberflächen **3**a und **3**b, die einen Winkel bilden, der nicht kleiner als 90° ist, an zwei Enden der benachbarten Käfige **3** in deren Bewegungsrichtung geformt. Wenn der Käfig **3** sich auf dem linearen Lastdurchgang **2**a befindet, ist eine Endoberfläche **3**a so positioniert, dass sie näherungsweise senkrecht zu dem Lastdurchgang **2**a ist. Wenn sich der Käfig **3** auf dem U-förmigen Richtungsänderungsdurchgang **2**b befindet, ist die andere Endoberfläche **3**b in die Richtung des Radius des Richtungsänderungsdurchgangs **2**b gerichtet. Somit laufen die Käfige **3** mit den Walzen **1** in dem Walzenumlaufweg **2** um, wobei die Endoberflächen **3**a und **3**b von benachbarten Käfigen **3** einander drücken.

[0005] Bei dem Kugelkäfig des Stands der Technik, der Kugeln in der Gestalt einer geraden Kette hält, zeichnet jedoch der Umlaufweg der Kugelschraube eine Spirale. Somit wird der Kugelkäfig so spiralförmig verwunden, dass Last auf den Kugelkäfig aufgebracht wird. Es ist eine Gefahr vorhanden, dass der Kugelkäfig durch diese Last beschädigt wird.

[0006] Auf der anderen Seite sind die Käfige **3**, durch die die Walzen **1**, die in dem Walzenführungsweg **2** der direkt wirkenden Führungseinrichtung angeordnet und aufgenommen sind, individuell gehalten werden, an den Fall angepasst, in dem der lineare Lastdurchgang und der U-förmige Richtungsänderungsdurchgang auf eine Ebene positioniert sind, so dass die Richtung der Walzen **1** zweidimensional geändert wird. Beispielsweise ist in einem Umlaufweg einer Walzenschraube jedoch keine zweidimensionale Richtungsänderung, sondern eine dreidimensionale Richtungsänderung vorhanden und entsprechend kann eine Verwindungsbewegung um die Bewegungsrichtung verlangt werden. Bei den vorher erwähnten Käfigen **3** wird den umlaufenden Käfigen **3** nicht ermöglicht, dass sie sich leicht um die Achsen der Walzen **1** jeweils drehen, so dass die Käfige **3** kaum solch eine komplexe Bewegung ausführen können. Dies ist, da die Gestalt jedes Käfigs **3** geformt ist, dass sie näherungsweise gleich der Querschnittsgestalt des Walzenumlaufwegs **2** ist, und da benachbarte Käfige **3** in Oberflächenkontakt miteinander an großflächigen, flachen Endoberflächen **3**a und **3**b sind. Weiterhin kann ein Schmiermittel kaum zwischen den Käfig **3** und eine korrespondierende Walze **1** eindringen, da der Umfang der Walze **1**, außer einem Teil des äußeren Umfangs **1**a, mit dem Käfig **3** bedeckt ist. Somit kann die Walze **1** nicht ausreichend geschmiert werden. Weiterhin ist näherungsweise der gesamte Querschnitt des Walzenumlaufwegs **2** mit dem Käfig **3** bedeckt. Es besteht ein Problem dahingehend, dass ein Stützelement zum Stützen des Käfigs **3** um den Käfig **3** vom Herunterfallen von dem Gleitelement zu hindern, wenn das Gleitelement aus der Laufschiene entfernt wird, kaum in dem Umlaufweg vorgesehen wird.

ZUSAMMENFASSUNG DER ERFINDUNG

[0007] Es ist eine Aufgabe der vorliegenden Erfindung, das oben stehende Ziel zu erreichen, und daher einen Walzenkäfig vorzusehen, der glatt umlaufen kann, selbst unter einem komplexen kinetischen Zustand, wie einem dreidimensionalen Richtungsänderungsdurchgang, und bei dem Schmieröl ausreichend den Walzen zugeführt werden kann, und eine direkt wirkende Führungseinrichtung und eine Walzenschraube vorzusehen, die solche Walzenkäfige verwenden.

[0008] Die vorliegende Erfindung wird unten stehend beschrieben. Obwohl die Referenzziffern in den beigefügten Zeichnungen in Klammern gesetzt sind, um das Verständnis der vorliegenden Erfindung einfach zu machen, ist die vorliegende Erfindung nicht auf die Ausführungsformen beschränkt, die auf den beigefügten Zeichnungen basieren.

[0009] Um das Problem zu lösen, sieht der Erfinder der vorliegenden Erfindung ein System vor, bei dem Walzen, die in einem Umlaufweg umlaufen, nicht in der Gestalt einer geraden Kette gehalten werden, sondern in Walzenkäfigen individuell gehalten werden, so dass die Walzen in einem Umlaufweg umlaufen, wobei der rückseitige Walzenkäfig den vorderseitigen Walzenkäfig drückt. Ferner, da lineare Bereiche und gekrümmte Bereiche hauptsächlich in dem Umlaufweg vorhanden sind, berücksichtigt die Erfinder die Gestalt von jedem Ende des Walzenkäfigs in einer Bewegungsrichtung davon, so dass eine Druckkraft glatt in sowohl den linearen Bereichen als auch in den gekrümmten Bereichen übertragen wird. Weiterhin sieht der Erfinder ein System vor, bei dem Walzenkäfige umlaufen können, wobei ihnen erlaubt wird, sich leicht um die Achsen der Walzen jeweils zu drehen, wenn die Walzenkäfige umlaufen, wobei sie einander pressen. Entsprechend können die Walzenkäfige auf einen dreidimensionalen, komplexen Umlaufweg unter der Annahme angepasst werden, dass die Walzen in dem Umlaufweg angeordnet sind und die Achsen von benachbarten Walzen im wesentlichen parallel zueinander gehalten werden.

[0010] Insbesondere ist gemäß einem ersten Aspekt der vorliegende Erfindung eine Walzenkäfiganordnung vorgesehen, die Walzenkäfige **15** zum individuellen und korrespondierenden Aufnehmen einer Vielzahl von Walzen **7** hat, die in einem Walzenumlaufweg umlaufen, der lineare und gekrümmte Bahnen umfasst, wobei: jeder der Walzenkäfige **15** dünn gestaltet ist, um gegenüberliegende Seitenoberflächen der Walze **7** und vordere und rückwärtige Oberflächen der Walze **7** in einer Bewegungsrichtung der Walze **7** zu halten; ein linearer Führungsbereich **16**a, **17**a und ein gekrümmter Führungsbereich **16**b, **17**b, die sich in einem Neigungswinkel voneinander unterscheiden, in gegenüberliegenden Endoberflächen des Walzenkäfigs **15** in einer Bewegungsrichtung des Walzenkäfigs **15** geformt sind; und der lineare Führungsbereich **16**a, **17**a des Walzenkäfigs **15** in Berührung mit einem benachbarten Walzenkäfig **15** in der linearen Bahn kommt und der gekrümmte Führungsbereich **16**b, **17**b des Walzenkäfigs **15** in Kontakt mit einem benachbarten Walzenkäfig **15** in der gekrümmten Bahn kommt. Durch das Vorsehen des Walzenkäfiganordnung wird daher das oben erwähnte Problem gelöst. Die Dicke des Walzenkäfigs **15** wird ausgewählt, dass sie nicht größer als 90%, vorzugsweise nicht größer als 60%, des Walzendurchmessers ist.

[0011] Gemäß dieser Erfindung können in sowohl linearen Bahnen als auch gekrümmten Bahnen, die eine Umlaufbahn bilden, benachbarte Walzenkäfige einander drücken, ohne die Position einer Walze zu beeinträchtigen, die sich vorderseitig in der Richtung der Bewegung der Walze befindet. Somit können Walzen ausgerichtet werden, dass ein glatter Umlauf erzielt werden kann. Weiterhin, da der Walzenkäfig dünn gestaltet ist, werden die folgenden Wirkungen erzielt.

(1) Benachbarte Walzenkäfige können einander drükken, wobei ihnen erlaubt wird, dass sie sich leicht um die Achsen von entsprechenden Walzen jeweils drehen. Als eine Folge kann der Walzenkäfig als ein Walzenkäfig erzielt werden, der für einen komplexen Umlaufweg, wie einen dreidimensionalen Richtungsänderungsdurchgang oder einen helixförmigen Lastabwälzdurchgang, der wie eine Schraube gestaltet ist, geeignet ist.

(2) Ein großer Raum kann zum Aufnehmen von Schmieröl in dem Umlaufweg sichergestellt werden. Somit können die Walzen ausreichend geschmiert werden.

(3) Ein Element zum Verhindern des Herunterfallens zum Stützen des Walzenkäfigs kann in dem Umlaufweg vorgesehen werden, so dass der Walzenkäfig nicht aus dem Mutterelement fallen kann, oder ähnlichem.

[0012] Gemäß einem zweiten Aspekt der Erfindung ist eine Walzenanordnung vorgesehen, die Walzenkäfige **31** zum individuellen und entsprechenden Zurückhalten einer Vielzahl von Walzen **7** hat, die in einem Walzenumlaufweg, der lineare und gekrümmte Bahnen beinhaltet, umlaufen, wobei: jeder der Walzenkäfige **31** dünn gestaltet ist, um die gegenüberliegenden Seitenoberflächen der Walze **7** zu halten, und entweder die vordere oder die rückwärtige Oberfläche der Walze **7** in einer Bewegungsrichtung der Walze **7**; ein linearer Führungsbereich **32**a und ein gekrümmter Führungsbereich **32**b, die sich in ihrem Neigungswinkel unterscheiden, in einer Endoberfläche des Walzenkäfigs **31** in einer Bewegungsrichtung des Walzenkäfigs **31** geformt sind; und der lineare Führungsbereich **32**a des Walzenkäfigs **31** in Kontakt mit einer benachbarten Walze **7** in der linearen Bahn kommt und der gekrümmte Führungsbereich **32**b des Walzenkäfigs **31** in Kontakt einer benachbarten Walze **7** in der gekrümmten Bahn kommt. Durch das Vorsehen der Walzenkäfiganordnung wird das oben erwähnte Problem daher gelöst.

[0013] Gemäß dieser Erfindung hält zusätzlich zu dem gleichen Betrieb und der gleichen Wirkung wie derjenigen der vorher erwähnten Erfindung der Walzenkäfig entweder die vordere oder die rückwärtige Oberfläche einer entsprechenden Walze in der Bewegungsrichtung der Walze. Somit wird der Raum, der durch einen Walzenkäfig in dem Umlaufweg eingenommen wird, reduziert, so dass die Anzahl der Walzen erhöht werden kann. Entsprechend kann die Lastkapazität einer direkt wirkenden Führungseinrichtung oder Walzenschraube, die solche Walzenkäfige verwendet, erhöht werden.

[0014] Gemäß einem dritten Aspekt der Erfindung wird bei dem ersten Aspekt der Erfindung jeder der linearen Führungsbereiche **16**a, **17**a und der gekrümmten Führungsbereiche **16**b, **17**b des Walzenkäfigs **15** geformt, dass er eine gekrümmte Oberfläche ist, die wie ein kreisförmiger Bogen im Querschnitt geformt ist, so dass sie in einen linearen Kontakt mit dem benachbarten Walzenkäfig **15** kommt.

[0015] Gemäß dieser Erfindung können benachbarte Walzenkäfige einander drücken, während ihnen mit Sicherheit ermöglicht wird, dass sie sich leicht um die Achsen der entsprechenden Walzen jeweils drehen.

[0016] Gemäß einem vierten Aspekt der Erfindung ist bei dem zweiten Aspekt der Erfindung jeder der linearen Führungsbereiche **32**a und gekrümmten Führungsbereiche **32**b des Walzenkäfigs **15** als eine gekrümmte Oberfläche in Übereinstimmung mit einem äußeren Umfang der Walze **7** geformt.

[0017] Gemäß dieser Erfindung können eine Walzen und ein Walzenkäfig, die einander benachbart sind, einander drücken, wobei dem Walzenkäfig mit Sicherheit ermöglicht wird, dass er sich leicht um die Achse einer entsprechenden

Walze dreht. Ferner, da der Walzenkäfig in Oberflächenkontakt mit einer Walze kommt, die sich an der Vorderseite oder Rückseite in der Bewegungsrichtung des Walzenkäfigs befindet, kann ein Berührungsoberflächendruck reduziert werden.

[0018] Gemäß einem fünften Aspekt der Erfindung ist bei der Walzenkäfiganordnung, wie sie dem ersten oder dritten Aspekt entspricht, ein Gelenkvorsprung **26** an einem Schnittpunkt zwischen dem linearen Führungsbereich **16**a und dem gekrümmten Führungsbereich **16**b in einer Endoberfläche des Walzenkäfigs **25** vorgesehen; und eine Gelenkaussparung **27** ist an einem Schnittpunkt zwischen dem linearen Führungsbereich **17**a und dem gekrümmten Führungsbereich **17**b in der anderen Endoberfläche des Walzenkäfigs **25** vorgesehen, so dass die Gelenkaussparung **27** mit dem Gelenkvorsprung **26** eines benachbarten Walzenkäfigs in Eingriff kommt.

[0019] Gemäß dieser Erfindung wird dem Walzenkäfig nur ermöglicht, dass er um ein Gelenk schwingt, das durch eine Kombination des Gelenkvorsprungs und der Gelenkaussparung gebildet wird, in einer Ebene, die die Achse einer entsprechenden Walze und die Bewegungsrichtung der Walze enthält. Somit kann verhindert werden, dass die Walze herunterfällt, selbst an einer Grenze, in der ein Übergang von einer linearen Bahn zu einer gekrümmten Bahn auftritt. Somit kann ein glatter Umlauf der Walze sichergestellt werden.

[0020] Gemäß einem sechsten Aspekt der Erfindung sind bei einem der ersten bis fünften Aspekte Vorsprünge **20**, die ein Herunterfallen verhindern, auf entweder dem Walzenkäfig **15** oder den gegenüberliegenden Seitenoberflächen der Walze **7** geformt; und Aussparungen **21** zum Verhindern des Herunterfallens sind in dem anderen von dem Walzenkäfig und den gegenüberliegenden Seitenoberflächen der Walze geformt, so dass die Vorsprünge zum Verhindern des Herunterfallens in die Aussparungen zum Verhindern des Herunterfallens eingepasst werden.

[0021] Gemäß dieser Erfindung kann verhindert werden, dass die Walze aus dem Walzenkäfig fällt. Beispielsweise kann selbst in dem Fall, in dem ein Gleitelement, wie ein Mutterelement, aus der Bahnschiene entfernt wird, der Walzenkäfig verhindern, dass die Walze aus dem Gleitelement herunterfällt, so dass verhindert werden kann, dass die Walze von dem Gleitelement fällt.

[0022] Gemäß einem siebten Aspekt der Erfindung ist bei einem der ersten bis sechsten Aspekte eine Dicke des Walzenkäfigs **15** gewählt, dass sie nicht kleiner als 50% eines Durchmessers der Walze ist. Wenn eine kegelförmige Walze als jede der Walzen verwendet wird, bedeutet der Ausdruck "Walzendurchmesser", der hier verwendet wird, den kleinsten Walzendurchmesser.

[0023] Wenn die Dicke von jedem der Walzenkäfige kleiner als 50% des Walzendurchmessers ist, dringt das vordere Ende des nachfolgenden Walzenkäfigs in dem Umlaufweg in die Lücke zwischen dem vorderseitigen Walzenkäfig und der Walzenabwälznut ein, so dass benachbarte Walzenkäfige einander überlappen. Als Folge ist eine Gefahr vorhanden, dass der Umlauf der Walzen stoppen könnte. Wenn die Dicke von jedem der Walzenkäfige nicht kleiner als 50% des Walzendurchmessers ist, können solche benachbarten Walzenkäfige daran gehindert werden, einander zu überlappen.

[0024] Ferner ist gemäß der Erfindung auch eine direkt wirkende Führungseinrichtung vorgesehen, die umfasst: eine Bahnwelle **41**, **51**, die eine Walzenabwälzoberfläche **41**a, **51**a enthält; ein Gleitelement **42**, **52**, das einen Walzenumlaufweg umfasst, der eine Lastabwälzoberfläche **42**a, **52**a entsprechend der Walzenabwälzoberfläche **41**a, **51**a umfasst, wobei das Gleitelement **42**, **52** an der Bahnwelle **41**, **51** angepasst ist, so dass es frei bewegbar relativ zu der Bahnwelle **41**, **51** ist; eine Vielzahl von Walzenpaaren **40**, **53**, die in dem Walzenumlaufweg angeordnet und darin aufgenommen sind, so dass sie in Übereinstimmung mit der Bewegung des Gleitelements **42**, **52** relativ zu der Bahnwelle **41**, **51** umlaufen; und eine Vielzahl von Walzenkäfigen **15** zum Halten der Vielzahl von Walzen **43**, **53** individuell und entsprechend, so dass die Vielzahl von Walzen **43**, **53** drehbar/verschiebbar ist, wobei: die Vielzahl von Walzen **43**, **53** angeordnet und aufgenommen ist, so dass die Achsen von benachbarten Walzen **43**, **53** näherungsweise parallel zueinander gehalten werden; jeder der Walzenkäfige **15** dünn gestaltet ist, um gegenüberliegende Seitenoberflächen einer entsprechenden der Walzen **7** und vordere und rückwärtige Oberflächen der Walze **7** in einer Bewegungsrichtung der Walze **7** zu halten; ein linearer Führungsbereich **16**a, **17**a und ein gekrümmter Führungsbereich **16**b, **17**b, die sich im Neigungswinkel voneinander unterscheiden, in jeder der gegenüberliegenden Endoberflächen des Walzenkäfigs **15** in einer Bewegungsrichtung des Walzenkäfigs **15** geformt sind; und der lineare Führungsbereich **16**a, **17**a des Walzenkäfigs **15** in Kontakt mit einem benachbarten Walzenkäfig **15** in einer linearen Bahn und der gekrümmte Führungsbereich **16**b, **17**b des Walzenkäfigs **15** in Kontakt mit einem benachbarten Walzenkäfig **15** in einer gekrümmten Bahn kommt.

[0025] Weiterhin ist gemäß der Erfindung auch eine direkt wirkende Führungseinrichtung vorgesehen, die umfasst: eine Bahnwelle **41**, **51**, die eine Walzenabwälzoberfläche **41**a, **51**a enthält ein Gleitelement **42**, **52**, das einen Walzenumlaufweg umfasst, der eine Lastabwälzoberfläche **42**a, **52**a entsprechend der Walzenabwälzoberfläche **41**a, **51**a umfasst, wobei das Gleitelement **42**, **52** in die Bahnwelle **41**, **51** eingepasst ist, so dass es frei bewegbar relativ zu der Bahnwelle **41**, **51** ist; eine Vielzahl von Walzen **43**, **53**, die in dem Walzenumlaufweg angeordnet und aufgenommen sind, so dass sie in Übereinstimmung mit der Bewegung des Gleitelements **42**, **52** relativ zu der Bahnwelle **41**, **51** umlaufen; und eine Vielzahl von Walzenkäfigen **15** zum Halten der Vielzahl von Walzen **43**, **53** individuell und entsprechend, so dass die Vielzahl von Walzen **43**, **53** drehbar/verschiebbar ist, wobei: die Vielzahl von Walzen **43**, **53** angeordnet und aufgenommen ist, so dass die Achsen von benachbarten Walzen **43**, **53** näherungsweise parallel zueinander gehalten werden; jeder der Walzenkäfige **31** dünn gestaltet ist, um gegenüberliegenden Seitenoberflächen einer entsprechenden der Walzen **7** und entweder eine vordere oder eine rückwärtige Oberfläche der Walze **7** in einer Bewegungsrichtung der Walze **7** zu halten; ein linearer Führungsbereich **32**a und ein gekrümmter Führungsbereich **32**b, die sich in ihrem Neigungswinkel unterscheiden, in einer Endoberfläche des Walzenkäfigs **31** in einer Bewegungsrichtung des Walzenkäfigs **31** geformt sind; und der lineare Führungsbereich **32**a des Walzenkäfigs **31** in Kontakt mit einer benachbarten Walze **7** in einer linearen Bahn kommt und der gekrümmten Führungsbereich **32**b des Walzenkäfigs **31** in Kontakt mit einer benachbarten Walze **7** in einer gekrümmten Bahn kommt.

[0026] Weiterhin ist gemäß der Erfindung auch eine Walzenschraube vorgesehen, die umfasst: eine Bahnwelle **5**, die eine helixförmige Walzenabwälzoberfläche **5**a enthält; ein Gleitelement **6**, das einen Walzenumlaufweg **8** umfasst, der eine helixförmige Walzenabwälzoberfläche **6**a enthält, die der Walzenabwälzoberfläche **5**a entspricht, wobei das Gleitelement **6** in die Bahnwelle **5** eingepasst ist, so dass es frei bewegbar relativ zu der Bahnwelle **5** ist; eine Vielzahl von Walzen **7**, die in dem Walzenumlaufweg **8** angeordnet und aufgenommen sind, so dass sie in Übereinstimmung mit der Bewegung des Gleitelements **6** relativ zu der Bahnwelle **5**

umlaufen; und eine Vielzahl von Walzenkäfigen **15** zum Halten der Vielzahl von Walzen **7** individuell und entsprechend, so dass die Vielzahl von Walzen **7** drehbar/verschiebbar ist, wobei: die Vielzahl von Walzen **7** angeordnet und aufgenommen ist, so dass Achsen von benachbarten Walzen **7** näherungsweise parallel zueinander gehalten werden, jeder der Walzenkäfige **15** dünn gestaltet ist, dass er gegenüberliegende Oberflächen einer entsprechenden der Walzen **7** und vordere und rückwärtige Oberflächen der Walzen **7** in einer Bewegungsrichtung der Walze **7** hält; ein linearer Führungsbereich **16**a, **17**a und ein gekrümmter Führungsbereich **16**b, **17**b, die sich in dem Neigungswinkel voneinander unterscheiden, in jeder der gegenüberliegenden Endoberflächen des Walzenkäfigs **15** in einer Bewegungsrichtung des Walzenkäfigs **15** geformt sind; und der lineare Führungsbereich **26**a, **17**a des Walzenkäfigs **15** in Kontakt mit einem benachbarten Walzenkäfig **15** in einer linearen Bahn kommt und der gekrümmte Führungsbereich **16**b, **17**b des Walzenkäfigs **15** in Kontakt mit einem benachbarten Walzenkäfig **15** in einer gekrümmten Bahn kommt.

[0027] Weiterhin ist gemäß der Erfindung auch eine Walzenschraube vorgesehen, die umfasst: eine Bahnwelle **5**, die eine helixförmige Walzenabwälzoberfläche **5**a umfasst; ein Gleitelement **6**, das einen Walzenumlaufweg **8** umfasst, der eine helixförmige Lastabwälzoberfläche **6**a entsprechend der Walzenabwälzoberfläche **5**a umfasst, wobei das Gleitelement **6** in die Bahnwelle **5** eingepasst ist, so dass es frei bewegbar relativ zu der Bahnwelle **5** ist; eine Vielzahl von Walzen **7**, die in dem Walzenumlaufweg **8** angeordnet und aufgenommen sind, so dass sie in Übereinstimmung mit der Bewegung des Gleitelements **6** relativ zu der Bahnwelle **5** umlaufen; und eine Vielzahl von Walzenkäfigen **15** zum Halten der Vielzahl von Walzen **7** individuell und entsprechend, so dass die Vielzahl von Walzen **7** drehbar/verschiebbar ist, wobei: die Vielzahl von Walzen **7** angeordnet und aufgenommen ist, so dass Achsen von benachbarten Walzen **7** näherungsweise parallel zueinander gehalten werden; jeder der Walzenkäfige **31** dünn gestaltet ist, um gegenüberliegende Seitenoberflächen einer entsprechenden der Walzen **7** zu halten, und entweder eine vordere oder eine rückwärtige Oberfläche der Walze **7** in einer Bewegungsrichtung der Walze **7**; ein linearer Führungsbereich **32**a und ein gekrümmter Führungsbereich **32**b, die im Neigungswinkel unterschiedlich sind, in einer Endoberfläche des Walzenkäfigs **31** in einer Bewegungsrichtung des Walzenkäfigs **31** geformt sind; und der lineare Führungsbereich **32**a des Walzenkäfigs **31** in Kontakt mit einer benachbarten Walze **7** in einer linearen Bahn kommt und der gekrümmte Führungsbereich **32**b des Walzenkäfigs **31** in Kontakt mit einer benachbarten Walze in einer gekrümmten Bahn kommt.

DETAILLIERTE BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSFORMEN

[0049] Nun wird eine Beschreibung detaillierter von bevorzugten Ausführungsformen der Erfindung unter Bezug auf die beigefügten Zeichnungen gegeben.

[0050] **Fig.** 1 zeigt eine Walzenschraube, bei der Walzenkäfige gemäß einer ersten Ausführungsform der vorliegenden Erfindung beinhaltet sind. Die Walzenschraube umfasst eine Schraubenwelle **5** (Bahnwelle), ein Mutterelement **6** (Gleitelement), und eine Vielzahl von Walzen **7**. Die Schraubenwelle **5** hat eine helixförmige Walzenabwälznut **5** in ihrer äußeren Umfangsoberfläche, so dass die helixförmige Walzenabwälznut **5**a als eine Walzenabwälzoberfläche dient. Das Mutterelement **6** hat einen Walzenumlaufweg in seiner inneren Umfangsoberfläche geformt. Der Walzenumlaufweg umfasst eine helixförmige Lastabwälznut **6**a, so dass die helixförmige Lastabwälznut **6**a als eine Lastabwälzoberfläche entsprechend der Walzenabwälznut **5**a dient. Das Mutterelement **6** ist an die Schraubenwelle **5** aufgepasst, so dass sie relativ bewegbar sind. Die Vielzahl von Walzen **7** ist in dem Walzenumlaufweg angeordnet und aufgenommen und läuft in Übereinstimmung mit der Relativbewegung des Mutterelements **6** zur Schraubenwelle **5** um. Die Vielzahl von Walzen **7** ist in dem Walzenumlaufweg so angeordnet und aufgenommen, dass Achsen von benachbarten Walzen **7** im wesentlichen parallel zueinander gehalten werden. In dem Walzenumlaufweg wird ein Lastabwälzdurchgang **8** zwischen der Walzenabwälznut **5**a, der Schraubenwelle **5** und der Lastabwälznut **6**a des Mutterelements **6** geformt. Das Mutterelement **6** hat ein Rückkehrrohr. Das Rückkehrrohr bildet einen Rückkehrdurchgang ohne Last, durch den ein Ende des Lastabwälzdurchgangs **8** mit dem anderen Ende des Lastabwälzdurchgangs **8** in Verbindung steht.

[0051] **Fig.** 2 zeigt das Rückkehrrohr **9**. Das Rückkehrrohr **9** hat einen Körperbereich **9**b und gegenüberliegende Endbereiche **9**a, die in bezug auf den Körperbereich **9**b gebogen sind. Die gegenüberliegenden Endbereiche **9**a sind in den Lastabwälzdurchgang eingepasst, so dass ein Abstand von einigen Schraubensteigungen zwischen den gegenüberliegenden Endbereichen **9**a verbleibt. Dabei ist das Rückkehrrohr **9** an dem Mutterelement **6** durch Rohrdrücken angebracht.

[0052] **Fig.** 3 zeigt die Schraubenwelle **5**. Die helixförmige Walzenabwälznut **5**a, die eine vorbestimmte Steigung hat, ist in der äußeren Umfangsoberfläche der Schraubenwelle **5** geformt. Die Walzenabwälznut **5**a ist im Querschnitt wie ein Trapezoid gestaltet. Jede der Walzen **7** wälzt sich auf einer Wandoberfläche **12**a oder **12**b der Walzenabwälznut **5**a ab.

[0053] Wie es in **Fig.** 1 gezeigt ist, ist das Mutterelement **6** im wesentlichen wie ein Zylinder gestaltet. Die helixförmige Lastabwälznut **6**a, die eine Steigung hat, die gleich der Steigung der Schraubenwelle **5** ist, ist in der inneren Umfangsoberfläche des Mutterelements **6** geformt. Die Lastabwälznut **6**a ist ebenfalls wie ein Trapezoid im Querschnitt geformt. Ein Vorsprung **10** zum Bilden der Lastabwälznut **6**a des Mutterelements **6** ist in die Walzenabwälznut **5**a eingepasst, so dass der innere Durchmesser des Mutterelements **6** kleiner ist als der äußere Durchmesser der Schraubenwelle **5**. Jede der Walzen **7** wälzt sich auf einer Wandoberfläche **11**a oder **11**b der Lastabwälznut **6**a ab. Die Lastabwälznut **6**a des Mutterelements **6** kann in der Mitte versetzt sein. Somit ist bis zu der Position des Versatzes ein Raum zum Anordnen der Walzen **7** zwischen der Wandoberfläche **12**b der Walzenabwälznut **5**a und der Wandoberfläche **11**b der Lastabwälznut **6**a geformt, und, nach der Versatzposition, ist ein Raum zum Anordnen der Walzen **7** zwischen der Wandoberfläche **12**a der Walzenabwälznut **5**a und der Wandoberfläche **11**a der Lastabwälznut **6**a geformt. Rückkehrrohrpasslöcher sind in dem Mutterelement **6** geformt, so dass die gegenüberliegenden Seiten des Rückkehrrohrs **9** in die Löcher jeweils eingeführt werden. Die Rückkehrrohrpasslöcher erstrecken sich in die Lastabwälznut **6**a.

[0054] Wie es aus **Fig.** 2 offensichtlich ist, hat das Rückkehrrohr **9** gegenüberliegende Endbereiche **9**a, die um etwa 90° in bezug auf den Körperbereich **9**b gebogen sind. Das heißt, das Rückkehrrohr **9** ist im wesentlichen in der Art eines Doppelgehäuses geformt. Ein Querschnitt des Rückkehrdurchgangs ohne Last des Rückkehrrohrs **9** wird in Übereinstimmung mit der Gestalt jeder Walze **7** bestimmt. Wie es in **Fig.** 2 gezeigt ist, sind die gegenüberliegenden Endbereiche **9**a nicht parallel zueinander, so dass die jeweiligen Richtungen der gegenüberliegenden Endbereiche **9**a einen Torsionswinkel $\theta 1$ bilden (der sich in Übereinstimmung mit dem Steigungswinkel ändert).

[0055] **Fig.** 4 und 6 zeigen Walzenkäfige **15** und Walzen **7**, die in der Walzenschraube beinhaltet sind. **Fig.** 4 ist eine Ansicht (Vorderansicht) in einer Richtung senkrecht zur Richtung der Achse jeder Walze **7** und senkrecht zur Richtung der Bewegung jeder Walze **7**. **Fig.** 5 ist eine Ansicht (Seitenansicht) aus der Richtung der Bewegung jeder Walze **7**. **Fig.** 6 ist eine Ansicht (Unteransicht) aus der Achsenrichtung jede Walze **7**. Walzenkäfige **15** der gleichen Anzahl wie derjenigen der Walzen **7** sind vorgesehen, um die Walzen **7** individuell aufzunehmen. Jeder der Walzenkäfige **15** ist dünn gestaltet, dass er eine vordere und rückwärtige Oberfläche einer entsprechenden Walze **7** in der Bewegungsrichtung der Walze **7** hält. Die frontale Gestalt des Walzenkäfigs **15** (gesehen aus der Richtung senkrecht zur Achse der Walze und senkrecht zur Bewegungsrichtung der Walze) ist wie ein Rahmen geformt. Die Dicke W jeder Seitenoberfläche des Walzenkäfigs **15** ist gesetzt, dass sie in einem Bereich von 50% bis 90%, vorzugsweise in einem Bereich von 50% bis 60% des Durchmessers der Walze ist. Dabei wird, wenn eine kegelförmige Walze als Walze **7** verwendet wird, der minimale Durchmesser der Walze eingesetzt.

[0056] Ein linearer Führungsbereich **16**a und ein gekrümmter Führungsbereich **16**b, die sich im Neigungswinkel voneinander unterscheiden, sind in einer Endoberfläche **16** eines Walzenkäfigs **15** in der Bewegungsrichtung des Walzenkäfigs **15** geformt. Ein linearer Führungsbereich **17**a und ein gekrümmter Führungsbereich **17**b, die sich im Neigungswinkel voneinander unterscheiden, sind in der anderen Endoberfläche **17** des Walzenkäfigs **15** in der Bewegungsrichtung des Walzenkäfigs **15** geformt. Die linearen Führungsbereiche **16**a und **17**a sind so geformt, dass sie im wesentlichen parallel zur Achse jeder Walze **7** sind. Die gekrümmten Führungsbereiche **16**b und **17**b sind so geformt, dass die gekrümmten Führungsbereiche **16**b und **17**b in radialen Richtungen jeweils gerichtet sind, wenn Walzenkäfige in einer gekrümmten Bahn angeordnet sind. Das heißt, in einer gekrümmten Bahn kommen die gekrümmten Führungsbereiche **16**b und **17**b des Walzenkäfigs **15** in Kontakt mit benachbarten Walzenkäfigen **15**, und in einer linearen Bahn kommen die linearen Führungsbereiche **16**a und **17**a des Walzenkäfigs **15** in Kontakt mit benachbarten Walzenkäfigen **15**. Die linearen Führungsbereiche **16**a und **17**a und die gekrümmten Führungsbereiche **16**b und **17**b des Walzenkäfigs **15** sind geformt, dass sie abschnittsweise kreisförmige, bogenförmige, gekrümmte Oberflächen sind, so dass sie in linearen Kontakt mit benachbarten Walzenkäfigen **15** kommen (siehe **Fig.** 6). Wie es in **Fig.** 5 gezeigt ist, sind vier Ecken von Seitenoberflächen des Walzenkäfigs **15** abgeschnitten, dass sie abgeschrägte Bereiche **18** sind. Somit kann verhindert werden, dass der Walzenkäfig **15** mit der Schraubenwelle **5** in Wechselwirkung tritt, selbst in dem Fall, in dem die Achse **19** der Walze **7** nicht senkrecht zur Mittellinie **5**c der Schraubenwelle **5** angeordnet ist, sondern wenn sie geneigt unter einem Winkel α ist, wie es in **Fig.** 1 gezeigt ist. Wie es in **Fig.** 4 gezeigt ist, ist ein Paar von Vorsprüngen zum Verhindern des Herunterfallens **20**, **20** auf oberen und unteren Bereichen des Walzenkäfigs **15** auf der Seite der Walze **7** geformt. Weiterhin ist ein Paar von Aussparungen **21**, **21** auf der Seitenoberfläche der Walze **7** geformt, so dass die Aussparungen **21** zu den Vorsprüngen **20**, **20** passen. Somit hält der Walzenkäfig **15** die Walze **7**, so dass sich die Walze **7** um ihre Achse **19** drehen kann. Dabei können die Vorsprünge **20** zum Verhindern des Herunterfallens auf der Seite der Walze **7** vorgesehen werden, wobei die

Aussparungen **21** zum Verhindern des Herunterfallens auf der Seite des Walzenkäfigs **15** vorgesehen werden können. Der Walzenkäfig **15** ist aus einem Kunstharz oder ähnlichem als einem Rohmaterial durch Spritzguss oder ähnliches gefertigt.

[0057] Eine Kegelwalze kann als Walze **7** verwendet werden. Der Scheitel Q des Konus der Kegelwalze befindet sich auf der Mittellinie **5**c der Schraubenwelle **5**. Somit wälzt die Kegelwalze ohne Rutschen zwischen der Lastabwälznut **6**a und der Walzenabwälznut **5**a ab. Dabei können die Querschnittsform der Walzenabwälznut **5**a, die Querschnittsform der Lastabwälznut **6**a und die Seitengestalt der Walze frei gewählt werden in Übereinstimmung mit der Last, Genauigkeit usw., die von der Walzenschraube verlangt wird.

[0058] Wie es in **Fig.** 1 gezeigt ist, werden, wenn die Schraubenwelle **5** gedreht wird, Walzen **7** und Walzenkäfige **15**, die in dem Lastabwälzdurchgang **8** in der Richtung des Umfangs der Schraubenwelle **5** abwälzen, wobei sie einer Last unterliegen, durch das Rückkehrrohr **9** aufgenommen. Die aufgenommenen Walzen **7** und Walzenkäfige **15** gelangen durch das Rückkehrrohr **9**. Dann werden die Walzen **7** und Walzenkäfige **15** zum Lastabwälzdurchgang **8** zurückgeführt, nach dem Abstand einiger Schraubensteigungen. Wenn die Richtung der Drehung der Schraubenwelle **5** umgedreht wird, laufen die jeweiligen Walzen **7** in umgekehrter Richtung um. Dabei kann das Mutterelement **6** in dem Zustand gedreht werden, dass die Schraubenwelle **5** als stationäre Seite vorgesehen wird. Auch in diesem Fall können die Walzen **7** auf der vorher erwähnten Weise umlaufen.

[0059] **Fig.** 7 zeigt Walzen **7** und Walzenkäfige **15**, die in dem Rückkehrrohr **9** und dem Lastabwälzdurchgang **8** umlaufen. Wie es in **Fig.** 7 gezeigt ist, drückt in einer linearen Bahn (in einem Rückkehrrohr **9**), die einen Umlaufweg bildet, ein linearen Führungsbereich **16**a eines Walzenkäfigs **15**, der sich an der rückwärtigen Seite in der Bewegungsrichtung **1** der Walze **7** befindet, einen linearen Führungsbereich **17**a eines anderen Walzenkäfigs **15**, der sich an der Vorderseite befindet. In einer gekrümmten Bahn (in einem Lastabwälzdurchgang **8**) drückt der gekrümmte Führungsbereich **16**b des rückseitigen Walzenkäfigs **15** den gekrümmten Führungsbereich **17**b des vorderseitigen Walzenkäfigs **15**. Sowohl in der linearen Bahn als auch in der gekrümmten Bahn kann der rückseitige Walzenkäfig **15** den vorderseitigen Walzenkäfig **15** drücken, ohne die Position der Walze **7** zu beeinträchtigen, die sich in der rückwärtigen Seite in der Bewegungsrichtung der Walzen befindet. Wenn eine Kegelwalze als jede der Walzen **7** verwendet wird, insbesondere in einer linearen Bahn, neigt die Walze **7** dazu, in einer Ebene zu fallen, die die Achse und die Bewegungsrichtung der Walze enthält. In der linearen Bahn kommen lineare Führungsbereiche **16**a und **17**a von benachbarten Walzenkäfigen **15** in engen Kontakt miteinander, wohingegen in der gekrümmten Bahn gekrümmten Führungsbereiche **16**b und **17**b der benachbarten Walzenkäfige **15** in engen Kontakt miteinander kommen. Als Folge sind die Walzen **7** so ausgerichtet, dass ein glatter Umlauf erzielt werden kann. In den meisten Fällen hat der Rückkehrdurchgang **9** in einer Nichtlastregion eine lineare Bahn, eine kreisförmige Bogenbahn, eine lineare Bahn und eine kreisförmige Bogenbahn. Wenn die Krümmung eines kreisförmigen Bogens **24** des Rückkehrrohrs **9** zusammenfallend mit der Krümmung des Lastabwälzdurchgangs **8** gestaltet ist, können Walzen **7** ausgerichtet werden, dass ein glatter Umlauf erzielt werden kann. Dies ist, da gekrümmte Führungsbereiche **16**b und **17**b von benachbarten Walzenkäfigen **15** in engen Kontakt miteinander selbst in dem kreisförmigen Bogenbereich des Rückkehrrohrs **9** kommen. Wenn die Krümmung des kreisförmigen Bogens **24** des Rückkehrwegs **9** nicht mit der Krümmung des Lastabwälzdurchgangs **8** zusammenfällt, können die gekrümmten Führungsbereiche **16**b und **17**b weiter in zwei Bereiche getrennt werden, die in ihrem Neigungswinkel unterschiedlich sind. Das heißt, Führungsbereiche können in drei Bereiche getrennt werden, beispielsweise einen linearen Führungsbereich, einen gekrümmten Führungsbereich für den Lastabwälzdurchgang und einen gekrümmten Führungsbereich für das Rückkehrrohr.

[0060] Wie es oben beschrieben ist, ist der Lastabwälzdurchgang **8** der Walzenschraube helixförmig geformt. Wie es oben unter Bezug auf **Fig.** 2 beschrieben ist, hat das Rückkehrrohr zum Ändern der Richtung der aufgenommenen Walze **7** eine Torsion (Torsionswinkel $\theta 1$) um die Bewegungsrichtung der Walze. Das heißt, bei der Walzenschraube ändern die Walzen **7** und Walzenkäfige **15** ihre Richtungen dreidimensional und machen eine komplexe Bewegung. Die vorher beschriebenen Walzenkäfige **15** sind für solch eine komplexe Bewegung angepasst. Wie es in **Fig.** 5 gezeigt ist, ist die Dicke W jeder Seite jedes Walzenkäfigs **15** klein gehalten. Weiterhin sind die linearen Führungsbereiche **16**a und **17**a (die in engem Kontakt sein sollen) und die gekrümmten Führungsbereiche **16**b und **17**b (die in engem Kontakt sein sollen) von benachbarten Walzenkäfigen **15** wie kreisförmige Bögen im Querschnitt geformt, so dass sie miteinander in linearen Kontakt kommen. Somit drücken solche benachbarten Walzenkäfige **15** einander, wobei ihnen ermöglicht wird, sich leicht um die Achsen der entsprechenden Walzen **7** jeweils zu drehen. Als Folge ändern die Walzenkäfige **15** frei ihre Richtung dreidimensional mit entsprechenden Walzen **7**, jeweils, so dass eine komplexe Bewegung, die von der Walzenschraube in dieser Ausführungsform verlangt wird, gemacht werden kann. Insbesondere, wenn die Achse **19** jeder Walze **7** nicht senkrecht zur Mittellinie **5**c der Schraubenwelle **5**, sondern geneigt unter einem bestimmten Winkel ist, wie es in **Fig.** 1 gezeigt ist, läuft die Walze **7** in einer schirmartigen, gekrümmten Bahn um. Daher müssen benachbarte Walzenkäfige **15** in engen Kontakt miteinander kommen, wobei ein Kreuzungswinkel β zwischen den benachbarten Walzenkäfigen **15** konstant gehalten wird, wie es in **Fig.** 8 gezeigt ist. Gemäß der vorliegenden Erfindung drücken benachbarte Walzenkäfige **15** einander, wobei ihnen ermöglicht wird, sich leicht um die Achsen von entsprechenden Walzen **7** jeweils zu drehen. Entsprechend können Walzenkäfige **15**, die ausreichend an eine solche Umlaufform angepasst sind, erhalten werden.

[0061] Da jeder der Walzenkäfige **15** dünn gemacht ist, kann ein großer Raum zum Aufnehmen von Schmieröl in dem Umlaufweg sichergestellt werden. Somit können die Walzen **7** ausreichend geschmiert werden. Weiterhin, da jeder der Walzenkäfige **15** dünn gestaltet ist, kann eine große Lücke zwischen den Walzenkäfigen **15** und der Lastabwälznut **6**a eingenommen werden. Somit kann ein Stützelement zum Stützen der Walzenkäfige **15** in dem Umlaufweg vorgesehen werden, um zu verhindern, dass die Walzenkäfige **15** aus dem Mutterelement **6** oder ähnlichem fallen.

[0062] **Fig.** 9 zeigt den Fall, in dem die Dicke jedes Walzenkäfigs **15** ausgewählt ist, dass sie kleiner als 50% des Walzendurchmessers ist. Wenn die Dicke des Walzenkäfigs **15** kleiner als 50% des Walzendurchmessers gemacht wird, dringt das vordere Ende des nachfolgenden Walzenkäfigs **15** in die Lücke zwischen dem vorderseitigen Walzenkäfig **15** und der Walzenabwälznut **5**a ein, so dass benachbarte Walzenkäfige **15** einander überlappen können. Als Folge ist eine Gefahr vorhanden, dass der Umlauf der Walzen **7** stoppen kann. Wenn die Dicke des Walzenkäfigs **15** ausgewählt wird, dass sie nicht kleiner als 50% des Walzendurchmessers ist, können benachbarte Walzenkäfige **15** daran gehindert werden, einander zu überlappen, wie es oben beschrieben ist.

[0063] **Fig.** 10 zeigt eine zweite Ausführungsform der vorliegenden Erfindung, die Walzen und Walzenkäfige betrifft, die in der Walzenschraube beinhaltet sind. Jeder der Walzenkäfige **25** hat im wesentlichen die gleiche Konfiguration wie diejenige der Walzenkäfige **15** gemäß der ersten Ausführungsform. Der Walzenkäfig **25** hat weiter einen Gelenkvorsprung **26** und eine Gelenkaussparung **27**, die zu dem Gelenkvorsprung **26** des benachbarten Walzenkäfigs **25** passt. Der Gelenkvorsprung **26** ist an einem Schnittpunkt zwischen dem linearen Führungsbereich **16**a und dem gekrümmten Führungsbereich **16**b auf einer Endoberfläche des Walzenkäfigs **25** in der Bewegungsrichtung der Walze **7** vorgesehen. Die Gelenkaussparung **27** ist an einem Schnittpunkt zwischen dem linearen Führungsbereich **17**a und dem gekrümmten Führungsbereich **17**b auf der anderen Endoberfläche des Walzenkäfigs **25** vorgesehen. Da der Gelenkvorsprung **26** und die Gelenkaussparung **27** auf der vorher erwähnten Weise vorgesehen sind, kann der Walzenkäfig **25** nur um ein Gelenk schwingen, das durch eine Kombination des Gelenkvorsprungs **26** und der Gelenkaussparung **27** gebildet wird, in einer Ebene, die die Achse einer entsprechenden Walze **7** und die Bewegungsrichtung **1** der Bewegung der Walze **7** enthält. Somit kann verhindert werden, dass die Walze **7** herunterfällt, selbst an der Grenze, an der die Walze sich von der linearen Bahn zur gekrümmten Bahn bewegt. Somit kann ein glatter Umlauf der Walze **7** sichergestellt werden.

[0064] **Fig.** 11 bis 13 und **Fig.** 14A bis 14C Zeigen eine dritte Ausführungsform der vorliegenden Erfindung, die Walzenkäfige betrifft, die in der Walzenschraube beinhaltet sind. **Fig.** 11 ist eine Ansicht (Vorderansicht) aus einer Richtung senkrecht zur Achse jeder Walze **7** und senkrecht zur Richtung (**1**) der Bewegung der Walze **7**. **Fig.** 12 ist eine Ansicht (Seitenabschnitt) von der rückwärtigen Seite in der Bewegungsrichtung der Walze **7**. **Fig.** 13 ist eine Ansicht (Unteransicht) aus der Richtung der Achse der Walze **7**. **Fig.** 14A bis 14C sind Ansichten, die den Fall zeigen, in dem Walzenkäfige mit Walzen **7** in einer Linie ausgerichtet sind. In dieser Ausführungsform ist jeder der Walzenkäfige **31** dünn gestaltet, um nur die gegenüberliegenden Seitenoberflächen einer entsprechenden Walze **7** und die Vorderoberfläche der gleichen Walze **7** in der Bewegungsrichtung der Walze **7** zu halten. Jeder der Walzenkäfige **31** ist in der Vorderansicht U-förmig gestaltet. Die Dicke W jeder Seite des Walzenkäfigs **31** ist gewählt, dass sie in einem Bereich von 50% bis 90%, vorzugsweise in einem Bereich von 50% bis 60%, des Walzendurchmessers ist.

[0065] Ein linearer Führungsbereich **32**a und ein gekrümmter Führungsbereich **32**b die sich im Neigungswinkel voneinander unterscheiden, sind in einer Endoberfläche des Walzenkäfigs **31** in dessen Bewegungsrichtung geformt. Der lineare Führungsbereich **32**a ist unter einem vorbestimmten Winkel in bezug auf die Achse der Walze **7** geneigt, so dass die Achsen von benachbarten Walzen **7** parallel zueinander gehalten werden. Der gekrümmte Führungsbereich **32**b ist so geneigt, dass die Walzenkäfige **31** in radialen Richtungen gerichtet sind, wenn die Walzenkäfige **31** in einer gekrümmten Bahn angeordnet sind. Das heißt, in einer gekrümmten Bahn kommt der gekrümmte Führungsbereich **32** in Kontakt mit einer benachbarten Walze **7**, und in einer linearen Bahn kommt der lineare Führungsbereich **32**a in Kontakt mit der benachbarten Walze **7**. Der lineare Führungsbereich **32**a und der gekrümmte Führungsbereich **32**b sind als eine gekrümmte Oberfläche entsprechend dem äußeren Umfang der Walze **7** geformt.

[0066] Entsprechend diesem Walzenkäfig **31** können der Walzenkäfig **31** und eine zum Walzenkäfig **31** benachbarte Walze **7** einander drücken, wobei dem Walzenkäfig **31** ermöglicht wird, sich leicht um die Achse einer entsprechenden Walze **7** auf die gleiche Weise zu drehen, wie bei dem Walzenkäfig **15** in der ersten Ausführungsform. Somit kann der Walzenkäfig **31** den gleichen Betrieb und die gleichen Wirkungen wie diejenigen des Walzenkäfigs **15**, die in der ersten Ausführungsform erzielt sind, erfüllen. Weiterhin, da der Walzenkäfig **31** in Oberflächenkontakt mit einer Walze **7** kommt, die sich an der Vorderseite oder Rückseite in der Bewegungsrichtung der Walze befindet, kann ein Kontaktoberflächendruck ebenfalls reduziert werden.

[0067] Im Beispiel dieser Walzenschraube werden Walzen **7**, die in der Walzenabwälznut **5**a der Schraubenwelle **5** sich abwälzen, durch das Rückkehrrohr **9** aufgenommen und um einige Steigungen zurückgebracht. Alternativ kann ein Ablenkungselement zum Einfangen von Walzen **7** in dem Mutterelement **6** vorgesehen werden. Das heißt, eine der Walzen **7**, die auf der Walzenabwälznut **5**a der Schraubenwelle **5** läuft, kann aus der Walzenabwälznut **5**a durch das Ablenkelement genommen werden, so dass die Walze **7** über den äußeren Durchmesserbereich der Schraubenwelle **5** springt und vor einer Steigung zur Walzenabwälznut **5**a zurückkehrt. Obwohl es nicht gezeigt ist, kann eine Walzenschraube des sogenannten Seitenabdecktyps verwendet werden. Das heißt, das Mutterelement **6** wird durch einen Mutterkörper gebildet, der eine Lastabwälznut darin geformt hat, und Seitenabdeckungen, die an gegenüberliegenden Enden des Mutterkörpers angebracht sind. Eine Walzenrückkehrdurchgang ist in dem Mutterkörper geformt. Ein Verbindungsdurchgang, durch den die Lastabwälznut und der Rückkehrdurchgang miteinander in Verbindung stehen, ist in jeder der Seitenabdeckungen geformt.

[0068] Die Walzenaufnahme gemäß der vorliegenden Erfindung ist nicht nur auf die Walzenschraube beschränkt, sondern kann auf eine direkt wirkende Führungseinrichtung, wie eine Linearführung oder einen Spline angewendet werden. Insbesondere kann der Walzenkäfig gemäß der vorliegenden Erfindung angepasst an eine direkt wirkende Führungseinrichtung werden, außer in dem Fall, in dem jede Walze zweidimensional in einer Ebene senkrecht zur Achse der Walze umläuft. Das heißt, der Walzenkäfig gemäß der vorliegenden Erfindung kann auf eine direkt wirkende Führungseinrichtung angepasst werden, die einen Umlaufweg hat, der so komplex ist, dass der Weg gebogen ist, wobei die Walze verwunden wird.

[0069] **Fig.** 15 zeigt eine lineare Führung, in der Walzenkäfige **15** gemäß der ersten Ausführungsform der vorliegenden Erfindung beinhaltet sind. Die lineare Führung ist eine gut bekannte Einrichtung zum Führen eines bewegbaren Körpers, wie einem Tisch auf einem stationären Bereich, wie einem Bett oder einem Sattel. Die lineare Führung hat eine Führungsschiene **41** (Bahnwelle), einen sich bewegenden Block (Gleitelement) **42** und eine Vielzahl von Walzen **43**. Die Führungsschiene **41** ist auf dem stationären Bereich angebracht und hat eine Walzenabwälznut **41**a, die entlang der Richtung von dessen Länge geformt ist, so dass die Walzenabwälznut **41** als eine Walzenabwälzoberfläche dient. Der sich bewegende Block **42** ist an der Führungsschiene **41** angebracht, so dass sie relativ bewegbar sind. Ein Walzenumlaufweg, der eine Lastabwälznut **42**a entsprechend der Walzenabwälznut **41**a der Führungsschiene **41** enthält, ist in dem sich bewegenden Block **42** geformt, so dass die Lastabwälznut **42**a als eine Lastabwälzoberfläche dient. Die Vielzahl von Walzen **43** ist in dem Walzenumlaufweg angeordnet und aufgenommen und läuft in dem Walzenumlaufweg in Übereinstimmung mit der Relativbewegung des sich bewegenden Blocks **42** zur Führungsschiene **41** um. Die Vielzahl von Walzen **43** ist in den Walzenkäfigen **15** individuell und entsprechend gehalten. Die Walzen **43** sind angeordnet und aufgenommen in dem Walzenumlaufweg, so dass die Achsen der Walzen **43** im wesentlichen parallel zueinander gehalten werden. Durch den endlosen Umlauf der Walzen **43** macht der sich bewegende Block **42**, der die Walzen stützt, eine lineare Bewegung entlang der Führungsschiene **41**.

[0070] Die Führungsschiene **41** ist schlank länglich, dass sie ein Rechteck im Querschnitt bildet. Eine Walzenabwälznut **41**a, die als eine Bahn dient, wenn eine Walze **43** sich abwälzt, ist in sowohl der linken als auch der rechten Seitenoberfläche der Führungsschiene **41** geformt, so dass sie sich über die gesamte Länge der Führungsschiene erstreckt. Obwohl **Fig.** 15 den Fall zeigt, in dem die Führungsschiene linear ist, kann die Erfindung auch auf den Fall angewendet werden, in dem die Schiene gekrümmt ist. Obwohl **Fig.** 15 den Fall zeigt, in dem zwei Walzenabwälznuten **41**a links und rechts vorgesehen sind, kann die Erfindung auch auf den Fall angewendet werden, in dem die Anzahl von Walzenabwälznuten variierend in Übereinstimmung mit dem Zweck der Verwendung der linearen Führung oder ähnlichem verändert wird.

[0071] Der sich bewegende Block **42** wird grob durch eine Kombination eines sich bewegenden Körpers **44** und ein Paar von Seitenabdeckungen (nicht gezeigt) geformt, die an gegenüberliegenden Enden des sich bewegenden Körpers **44** angebracht sind. Zwei Lastabwälznuten **42**a entsprechend den Walzenabwälznuten **41**a sind in dem sich bewegenden Körper **44** vorgesehen. Die Kombination der Lastabwälznuten **42**a und der Walzenabwälznuten **41**a bildet zwei Lastabwälzdurchgänge C zwischen der Führungsschiene **41** und dem sich bewegenden Block **42**.

[0072] Zwei Rückkehrdurchgänge D, die sich parallel zu den Lastabwälzdurchgängen C jeweils erstrecken, und Richtungsänderungsdurchgänge B zum Verbinden der Lastabwälzdurchgänge C mit den Rückkehrdurchgängen D sind jeweils weiter in dem sich bewegenden Körper **44** vorgesehen. Die Kombination der Lastabwälzdurchgänge C, der Rückkehrdurchgänge D und dem Paar von Richtungsänderungsdurchgängen zum Verbinden der Lastabwälzdurchgänge C mit den Rückkehrdurchgängen D jeweils bildet einen Walzenumlaufweg. Jeder der Richtungsänderungsdurchgänge B hat eine dreidimensionale komplexe Bahn.

[0073] Wenn sich der sich bewegende Block **42** entlang der Führungsschiene **41** bewegt, wälzt die Walze **43** in dem Lastabwälzdurchgang C von einem Ende zum anderen Ende ab, wobei die Walze **43** eine Last von dem sich bewegenden Black **42** erfährt. Dann wird jede der Walzen **43** durch einen Richtungsänderungsdurchgang B eingefangen und zu dem Rückkehrdurchgang D gebracht. Die Walze **43** wird weiter zu einem Ende des Lastabwälzdurchgangs C durch den gegenüberliegenden Richtungsänderungsdurchgang B zurückgebracht. Bei dieser Gelegenheit drückt in den Lastabwälzdurchgängen C und Rückkehrdurchgängen D, die eine lineare Bahn bilden, der lineare Führungsbereich des rückwärtigen Walzenkäfigs **15** den linearen Führungsbereich des vorderseitigen Walzenkäfigs **15**. In dem Richtungsänderungsdurchgang B, der eine gekrümmte Bahn bildet, drückt der gekrümmte Führungsbereich des rückseitigen Walzenkäfigs **15** den gekrümmten Führungsbereich des vorderseitigen Walzenkäfigs **15**. Sowohl in der linearen Bahn als auch in der gekrümmten Bahn kann der rückseitige Walzenkäfig **15** den vorderseitigen Walzenkäfig **15** drücken, ohne die Position der Walze **7** zu beeinträchtigen, die sich in der Vorderseite in der Bewegungsrichtung der Walzen befindet.

[0074] Wie es oben beschrieben ist, ist jede Seitenoberfläche des Walzenkäfigs **15** dünn gestaltet, und der lineare Führungsbereich und der gekrümmte Führungsbereich zum Bringen von benachbarten Walzenkäfigen in engen Kontakt miteinander sind wie kreisförmige Bögen im Querschnitt geformt, so dass sie in linearen Kontakt mit benachbarten Walzenkäfigen kommen. Somit drücken benachbarte Walzenkäfige einander, während ihnen ermöglicht wird, sich leicht um die Achsen der entsprechenden Walzen jeweils zu drehen. Auf solch eine Weise können die Walzenkäfige **15** mit den Walzen **43** ihre Richtung frei dreidimensional ändern. Somit können die Walzenkäfige **15** solch eine komplexe Bewegung machen, wie diejenige, die von den Richtungsänderungsdurchgängen B der linearen Führung in dieser Ausführungsform verlangt wird.

[0075] Obwohl diese Ausführungsform den Fall gezeigt hat, in dem die Relativbewegung des sich bewegenden Blocks **42** zur Führungsschiene **41** linear gestaltet ist, kann die vorliegende Erfindung vorzugsweise auch auf eine Führungseinrichtung angewendet werden, die so konfiguriert ist, dass die Relativbewegung gekrümmt ist.

[0076] **Fig.** 16 zeigt einen Spline, in dem Walzenkäfige gemäß der ersten Ausführungsform der vorliegenden Erfindung beinhaltet sind. Der Spline hat eine Splinewelle **51** und einen äußeren Zylinder **52**. Die Splinewelle **51** dient als ein Bahnelement, wohingegen der äußere Zylinder **52** als ein Gleitelement dient. Der äußere Zylinder **52** ist auf der Splinewelle **51** montiert, so dass er durch eine Vielzahl von Walzen **53** bewegbar ist. Die Vielzahl von Walzen **53** ist in Walzenkäfigen **15** individuell gehalten, die in der ersten Ausführungsform erzielt werden. Weiterhin werden die Achsen von benachbarten Walzen im wesentlichen parallel zueinander gehalten.

[0077] Die Splinewelle **51** ist wie eine Säule eines tatsächlichen Kreises geformt. Eine Vielzahl von Walzenabwälznuten **51**a, die als Walzenbahnen wirken und als Walzenabwälzoberflächen dienen, die sich in der radialen Richtung der Splinewelle **51** erstrecken, sind in einer Oberfläche der Splinewelle **51** geformt. Beispielsweise sind sechs Walzenabwälznuten **51**a geformt.

[0078] Der äußere Zylinder **52**, der auf die Splinewelle **51** montiert ist, hat Lastabwälznuten **52**a, die den Walzenabwälznuten **51**a entsprechen. Die Lastabwälznuten **52**a dienen als Lastabwälzoberflächen. Eine Vielzahl von Walzen **53** ist in dem Walzenumlaufweg so angeordnet, dass die Walzen **53** zusätzlich zur linearen Bewegung des äußeren Zylinders **52** relativ zu der Splinewelle **51** umlaufen. Ein Lastabwälzdurchgang C ist zwischen jeder Lastabwälznut **52**a, die in dem äußeren Zylinder **52** geformt ist, und einer entsprechenden Walzenabwälznut **51**a, die in der Splinewelle **51** geformt ist, geformt. Ein Nichtlastrückkehrdurchgang D ist benachbart zu jedem Lastabwälzdurchgang C geformt. In dem Nichtlastrückkehrdurchgang D wälzen Walzen **53**, die von der Last freigegeben sind, ab. Ein Richtungsänderungsdurchgang B zum Verbinden jedes Lastabwälzdurchgangs C mit einem entsprechenden Nichtlastrückkehrdurchgang D ist weiter in dem äußeren Zylinder **52** geformt. Der Richtungsänderungsdurchgang B hat eine dreidimensionale, komplexe Bahn, wie diejenige der linearen Führung.

[0079] Wenn der äußere Zylinder **52** relativ zu der Splinewelle **51** bewegt wird, wälzt die Walze **53** in dem Nichtlastabwälzdurchgang C ab, wobei sie Last erfährt. Somit ändert die Walze **53** ihre Richtung in dem Richtungsänderungsdurchgang B und bewegt sich zu dem Nichtlastrückkehrdurchgang D. In dem Nichtlastrückkehrdurchgang D bewegt sich die Walze **53** in der umgekehrten Richtung gegen den Lastabwälzdurchgang C. Die Walzen **53**, die sich in dem Nichtlastrückkehrdurchgang D bewegen, ändern ihre Richtung wiederum in dem anderen Richtungsänderungsdurchgang B und kehren zu dem Nichtlastrückkehrdurchgang C wiederum zurück. Dabei drückt in den Lastabwälzdurchgängen C und Nichtlastrückkehrdurchgängen D, die lineare Bahnen bilden, der lineare Führungsbereich des rückseitigen Walzenkäfigs **15** den linearen Führungsbereich des vorderseitigen Walzenkäfigs **15**. In dem Richtungsänderungsdurchgang B, der eine gekrümmte Bahn bildet, drückt der gekrümmte Führungsbereich des rückseitigen Walzenkäfigs **15** den gekrümmten Führungsbereich des vorderseitigen Walzenkäfigs **15**. Sowohl in der linearen Bahn als auch in der gekrümmten Bahn kann der rückseitige Walzenkäfig **15** den vorderseitigen Walzenkäfig **15** drücken, ohne die Position der Walze **53** zu beeinträchtigen, die sich vorne in der Bewegungsrichtung der Walze befindet.

[0080] Weiterhin ist jede Seitenoberfläche des Walzenkäfigs **15** dünn gestaltet, und der lineare Führungsbereich und gekrümmte Führungsbereich zum Bringen benachbarter Walzenkäfige **15** in engen Kontakt miteinander sind wie kreisförmige Bögen im Querschnitt geformt, so dass sie in linearen Kontakt mit benachbarten Walzenkäfigen kommen. Somit drücken benachbarte Walzenkäfige **15** einander, wobei sie sich leicht um die Achsen von entsprechenden Walzen jeweils drehen können. Auf solch eine Weise können die Walzenkäfige **15** mit den Walzen **53** ihre Richtung frei dreidimensional ändern. Somit können die Walzenkäfige **15** eine solche komplexe Bewegung machen, wie sie von den Richtungsänderungsdurchgängen B der Splines in dieser Ausführungsform verlangt wird.

[0081] Wie es oben beschrieben ist, wird gemäß der vorliegenden Erfindung ein Walzenkäfig dünn gestaltet, um gegenüberliegende Seitenoberflächen einer entsprechenden Walze und vordere und rückwärtige Oberflächen der Walze in der Bewegungsrichtung der Walze zu halten. Ein linearer Führungsbereich und ein gekrümmter Führungsbereich, die sich im Neigungswinkel voneinander unterscheiden, sind in jeder Endoberfläche des Walzenkäfigs in der Bewegungsrichtung des Walzenkäfigs geformt. Somit kommt in der gekrümmten Bahn der gekrümmte Führungsbereich in Kontakt mit einem benachbarten Walzenkäfig. In der linearen Bahn kommt der lineare Führungsbereich in Kontakt mit einem benachbarten Walzenkäfig. Somit kann in sowohl der linearen Bahn als auch der gekrümmten Bahn, die eine Umlaufbahn bilden, der rückwärtige Walzenkäfig den vorderseitigen Walzenkäfig drücken, ohne die Position der Walze zu beeinträchtigen, die sich vorne in der Bewegungsrichtung der Walzen befindet. Somit können die Walzen ausgerichtet werden, dass ein glatter Umlauf erzielt werden kann. Ferner, da der Walzenkäfig dünn gestaltet ist, werden die folgenden Wirkungen erzielt.

(1) Benachbarte Walzenkäfige können einander drükken, wobei ihnen ermöglicht wird, sich leicht um die Achsen von entsprechenden Walzen jeweils zu drehen. Als eine Folge kann der Walzenkäfig als ein Walzenkäfig erzielt werden, der für einen komplexen Umlaufweg, wie einen dreidimensionalen Richtungsänderungsdurchgang oder einen helixförmigen Lastabwälzdurchgang, der wie eine Schraube geformt ist, geeignet ist.

(2) Ein großer Raum kann sichergestellt werden, um Schmieröl in dem Umlaufweg zu bevorraten. Somit können die Walzen ausreichend geschmiert werden.

(3) Ein Element zum Verhindern des Herunterfallens zum Stützen des Walzenkäfigs kann in dem Umlaufweg vorgesehen werden, so dass der Walzenkäfig am Herunterfallen aus dem Mutterelement oder ähnlichem gehindert wird.

Patentansprüche

1. Walzenkäfiganordnung, umfassend:
eine Vielzahl von Walzenkäfigen zum individuellen, entsprechenden Aufnehmen einer Vielzahl von Walzen, die in einem Walzenumlaufweg, der eine lineare und eine gekrümmte Bahn beinhaltet, umlaufen;
wobei jeder der Walzenkäfige dünn gestaltet ist, dass er gegenüberliegende Seitenoberflächen der Walze und vordere und rückwärtige Oberflächen der Walze in einer Bewegungsrichtung der Walze hält;
wobei ein linearer Führungsbereich und ein gekrümmter Führungsbereich, die sich voneinander im Neigungswinkel unterscheiden, an gegenüberliegenden Endoberflächen des Walzenkäfigs in einer Bewegungsrichtung des Walzenkäfigs geformt sind; und
wobei der lineare Führungsbereich des Walzenkäfigs in Kontakt mit einem benachbarten Walzenkäfig in der linearen Bahn und der gekrümmte Führungsbereich des Walzenkäfigs in Kontakt mit dem benachbarten Walzenkäfig in der gekrümmten Bahn kommt.

2. Walzenkäfiganordnung, umfassend:
eine Vielzahl von Walzenkäfigen zum individuellen, entsprechenden Aufnehmen einer Vielzahl von Walzen, die in einem Walzenumlaufweg umlaufen, der eine lineare und eine gekrümmte Bahn umfasst;
wobei jeder der Walzenkäfige dünn gestaltet ist, dass er gegenüberliegende Seitenoberflächen der Walze und entweder die vordere oder rückwärtige Oberfläche der Walze in einer Bewegungsrichtung der Walze hält;
wobei ein linearer Führungsbereich und ein gekrümmter Führungsbereich, die sich im Neigungswinkel voneinander unterscheiden, in einer Endoberfläche des Walzenkäfigs in einer Bewegungsrichtung des Walzenkäfigs geformt sind; und
wobei der lineare Führungsbereich des Walzenkäfigs in Kontakt mit einer benachbarten Walze in der linearen Bahn und der gekrümmte Führungsbereich des Walzenkäfigs in Kontakt mit der benachbarten Walze in der gekrümmten Bahn kommt.

3. Walzenkäfiganordnung nach Anspruch 1, wobei jeder von dem linearen Führungsbereich und dem gekrümmten Führungsbereich des Walzenkäfigs geformt ist, dass er eine gekrümmte Oberfläche ist, die wie ein kreisförmiger Bogen im Querschnitt geformt ist, so dass sie in linearen Kontakt mit dem benachbarten Walzenkäfig kommt.

4. Walzenkäfiganordnung nach Anspruch 2, wobei jeder von dem linearen Führungsbereich und dem gekrümmten Führungsbereich des Walzenkäfigs geformt ist, dass er eine gekrümmte Oberfläche ist in Übereinstimmung mit einem äußeren Umfang der Walze.

5. Walzenkäfiganordnung nach Anspruch 1 oder 3, wobei ein Gelenkvorsprung an einem Schnittpunkt zwischen dem linearen Führungsbereich und dem gekrümmten Führungsbereich in einer Endoberfläche des Walzenkäfigs in der Bewegungsrichtung des Walzenkäfigs vorgesehen ist; und
wobei eine Gelenkaussparung an einem Schnittpunkt zwischen dem linearen Führungsbereich und dem gekrümmten Führungsbereich in der anderen Endoberfläche des Walzenkäfigs in der Bewegungsrichtung des Walzenkäfigs vorgesehen ist, so dass die Gelenkaussparung mit dem Gelenkvorsprung eines benachbarten Walzenkäfigs in Eingriff kommt.

6. Walzenkäfiganordnung nach Anspruch 1, wobei Vorsprünge zum Verhindern des Herunterfallens an entweder dem Walzenkäfig oder gegenüberliegenden

Seitenoberflächen der Walze geformt sind; und wobei Aussparungen zum Verhindern des Herunterfallens in dem anderen von dem Walzenkäfig und den gegenüberliegenden Seitenoberflächen der Walze geformt sind, so dass die Vorsprünge zum Verhindern des Herunterfallens in die Aussparungen zum Verhindern des Herunterfallens eingepasst sind.

7. Walzenkäfiganordnung nach Anspruch 1, wobei eine Dicke des Walzenkäfigs gewählt ist, dass sie nicht kleiner als 50% eines Durchmessers der Walze ist.

8. Direkt wirkende Führungseinrichtung, umfassend:
eine Bahnwelle, umfassend eine Walzenabwälzoberfläche;
ein Gleitelement, das einen Walzenumlaufweg umfasst, der eine Lastabwälzoberfläche entsprechend der Walzenabwälzoberfläche enthält, wobei das Gleitelement mit der Bahnwelle in Passung gebracht ist, so dass es frei bewegbar relativ zu der Bahnwelle ist;
eine Vielzahl von Walzen, die in dem Walzenumlaufweg angeordnet und aufgenommen sind, so dass sie in Übereinstimmung mit der Bewegung des Gleitelements relativ zu der Bahnwelle umlaufen; und
eine Vielzahl von Walzenkäfigen zum Halten der Vielzahl von Walzen individuell und entsprechend, so dass die Vielzahl von Walzen drehbar/verschiebbar ist;
wobei die Vielzahl von Walzen angeordnet und aufgenommen ist, so dass die Achsen von benachbarten Walzen näherungsweise parallel zueinander gehalten werden;
wobei jeder der Walzenkäfige dünn gestaltet ist, dass er gegenüberliegende Seitenoberflächen von benachbarten Walzen und vordere und rückwärtige Oberflächen der Walze in einer Richtung der Bewegung der Walze hält;
wobei ein linearer Führungsbereich und ein gekrümmter Führungsbereich, die im Neigungswinkel voneinander sich unterscheiden, in jeder von gegenüberliegenden Endoberflächen des Walzenkäfigs in einer Bewegungsrichtung des Walzenkäfigs geformt sind; und
wobei der lineare Führungsbereich des Walzenkäfigs in Kontakt mit einem benachbarten Walzenkäfig in einer linearen Bahn und der gekrümmte Führungsbereich des Walzenkäfigs in Kontakt mit dem benachbarten Walzenkäfig in einer gekrümmten Bahn kommt.

9. Direkt wirkende Führungseinrichtung, umfassend:
eine Bahnwelle, die eine Walzenabwälzoberfläche enthält;
ein Gleitelement, das einen Walzenumlaufweg umfasst, der eine Lastabwälzoberfläche entsprechend der Walzenabwälzoberfläche enthält, wobei das Gleitelement an die Bahnwelle angepasst ist, so dass es frei bewegbar relativ zu der Bahnwelle ist;
eine Vielzahl von Walzen, die in dem Walzenumlaufweg angeordnet und aufgenommen sind, so das sie in Übereinstimmung mit der Bewegung des Gleitelements relativ zu der Bahnwelle umlaufen; und
eine Vielzahl von Walzenkäfigen zum Halten der Vielzahl von Walzen individuell und entsprechend, so dass die Vielzahl von Walzen drehbar/verschiebbar ist;
wobei die Vielzahl von Walzen angeordnet und aufgenommen ist, so dass die Achsen von benachbarten Walzen näherungsweise parallel zueinander gehalten werden;
wobei jeder der Walzenkäfige dünn gestaltet ist, dass er gegenüberliegende Seitenoberflächen von entsprechenden der Walzen und entweder die vordere oder die rückwärtige Oberfläche der Walze in einer Bewegungsrichtung der Walze hält;
wobei ein linearer Führungsbereich und ein gekrümmter Führungsbereich, die sich im Neigungswinkel voneinander unterscheiden, in einer Endoberfläche des Walzenkäfigs in einer Bewegungsrichtung des Walzenkäfigs geformt sind; und
wobei der lineare Führungsbereich des Walzenkäfigs in Kontakt mit einer benachbarten Walze in einer linearen Bahn und der gekrümmte Führungsbereich des Walzenkäfigs in Kontakt mit der benachbarten Walze in einer gekrümmten Bahn kommt.

10. Walzenschraube, umfassend:
eine Bahnwelle, die eine helixförmige Walzenabwälzoberfläche enthält;
ein Gleitelement, das einen Walzenumlaufweg umfasst, der eine helixförmige Lastabwälzoberfläche enthält, die der Walzenabwälzoberfläche entspricht, wobei das Gleitelement an die Bahnwelle angepasst ist, so dass es frei bewegbar relativ zu der Bahnwelle ist;
eine Vielzahl von Walzen, die in dem Walzenumlaufweg angeordnet und aufgenommen sind, so dass sie in Übereinstimmung mit der Bewegung des Gleitelements relativ zu der Bahnwelle umlaufen; und
eine Vielzahl von Walzenkäfigen zum Halten der Vielzahl von Walzen individuell und entsprechend, so dass die Vielzahl von Walzen drehbar/verschiebbar ist;
wobei die Vielzahl von Walzen angeordnet und aufgenommen ist, so dass die Achsen von benachbarten Walzen näherungsweise parallel zueinander gehalten werden;
wobei jeder der Walzenkäfige dünn gestaltet ist, dass er gegenüberliegende Seitenoberflächen einer entsprechenden der Walzen und vordere und rückwärtige Oberflächen der Walze in einer Bewegungsrichtung der Walze hält;
wobei ein linearer Führungsbereich und ein gekrümmter Führungsbereich, die im Neigungswinkel voneinander unterschiedlich sind, in jeder der gegenüberliegenden Endoberflächen des Walzenkäfigs in einer Bewegungsrichtung des Walzenkäfigs geformt sind; und
wobei der lineare Führungsbereich des Walzenkäfigs in Kontakt mit einem benachbarten Walzenkäfig in einer linearen Bahn und der gekrümmte Führungsbereich des Walzenkäfigs in Kontakt mit dem benachbarten Walzenkäfig in einer gekrümmten Bahn kommt.

11. Walzenschraube, umfassend:
eine Bahnwelle, die eine helixförmige Walzenabwälzoberfläche enthält;
ein Gleitelement, das einen Walzenumlaufweg umfasst, der eine helixförmige Lastabwälzoberfläche enthält, die der Walzenabwälzoberfläche entspricht, wobei das Gleitelement an die Bahnwelle angepasst ist, so dass es frei bewegbar relativ zu der Bahnwelle ist;
eine Vielzahl von Walzen, die angeordnet und aufgenommen in dem Walzenumlaufweg sind, so dass sie in Übereinstimmung mit der Bewegung des Gleitelements relativ zu der Bahnwelle umlaufen; und
eine Vielzahl von Walzenkäfigen zum Halten der Vielzahl von Walzen individuell und entsprechend, so dass die Vielzahl von Walzen drehbar/verschiebbar ist;
wobei die Vielzahl von Walzen angeordnet und aufgenommen ist, so dass die Achsen von benachbarten Walzen näherungsweise parallel zueinander gehalten werden;
wobei jeder der Walzenkäfige dünn gestaltet ist, um gegenüberliegende Seitenoberflächen von einer entsprechenden der Walzen und entweder die vordere oder die rückwärtige Oberfläche der Walze in einer Bewegungsrichtung der Walze zu halten;

wobei ein linearer Führungsbereich und ein gekrümmter Führungsbereich, die sich im Neigungswinkel voneinander unterscheiden, in einer Endoberfläche des Walzenkäfigs in einer Richtung der Bewegung des Walzenkäfigs geformt sind; und
wobei der lineare Führungsbereich des Walzenkäfigs in Kontakt mit einer benachbarten Walze in einer linearen Bahn und der gekrümmte Führungsbereich des Walzenkäfigs in Kontakt mit der benachbarten Walze in einer gekrümmten Bahn kommt.

Beschreibung

Hintergrund der Erfindung

Die vorliegende Erfindung betrifft eine Wälzkörperführungsvorrichtung und insbesondere ein Verfahren zur Bestimmung einer Länge einer Laufwegoberfläche und eines Durchmessers eines Wälzkörpers einer Wälzkörperführungsvorrichtung, eine Wälzkörperführungsvorrichtung und ein Wälzkörperführungssystem, in dem obiges Bestimmungsverfahren Anwendung findet.

Als eine Wälzkörperführungsvorrichtung zum Führen einer linearen oder gekrümmten Bewegung sind lineare Führungsvorrichtungen, Kugellaufbuchsen, Kugelspindelmaschinen und dergleichen bekannt. In derartigen Wälzkörperführungsvorrichtungen weist die lineare Kugelführung eine Spurschiene und einen bewegbaren Block als bewegliches Element auf, das derart angeordnet ist, dass es mit Bezug auf die Spurschiene über eine Anzahl von Kugeln als Wälzkörper bewegbar ist. Ein lineares Kugelführungssystem als ein Wälzkörperführungssystem ist ein System, bei dem die lineare Führungsvorrichtung mit einem Maschinenwerkzeugtisch oder dergleichen zusammengesetzt ist und beispielsweise zwei bewegbare Blöcke jeweils mit zwei Spurschienen zum Tragen des Tisches, also insgesamt vier bewegbaren Blökken vorgesehen sind.

In diesem System wird auf den Tisch eine radiale Last, eine horizontale Last und entsprechende Kraftmomente einer Abrolllast, einer Wende-Rolllast, sowie einer Längsmomentenlast als externe Kräfte aufgebracht. Der Tisch verändert seine Lage aufgrund dieser externen Kräfte, wobei die Stellung des Tisches fünf variable Komponenten einer vertikalen (senkrechten) Versetzung, einer horizontalen (transversalen) Versetzung, eines Abrollwinkels, eines Verdrehwinkels und eines Kippwinkels beinhaltet.

Der bewegbare Block hat eine Laufwegoberfläche, wobei eine Anzahl von Kugeln zwischen dieser Laufwegoberfläche und einer Spurschiene als Spurschaft angeordnet sind. In der linearen Wälzkörperführungsvorrichtung laufen die Kugeln gemäß der Bewegung des bewegbaren Elements, womit eine relative Position der Kugeln und des bewegbaren Blocks variabel ist. Diese Änderung der relativen Position der Kugeln und des bewegbaren Blocks verursacht eine Änderung der Lastverteilung in dem linearen Führungssystem, womit die Stellung des Tisches verändert wird. Der Betrag dieser Änderung der Stellung des Tisches stellt die Genauigkeit des linearen Kugelführungssystems dar, wobei demgemäß die Präzision des linearen Kugelführungssystems verbessert werden kann, wenn der Betrag der änderbaren Tischstellung verringert wird.

Zusammenfassung der Erfindung

Im Hinblick auf die zum Stand der Technik oben erwähnten Umstände ist es eine Aufgabe der vorliegenden Erfindung, ein Verfahren zur Bestimmung einer Länge einer Laufwegoberfläche eines bewegbaren Elements und eines Durchmessers eines Wälzkörpers einer Wälzkörperführungsvorrichtung, sowie eine Wälzkörperführungsvorrichtung und ein Wälzkörperführungssystem vorzusehen, bei dem ein derartiges Bestimmungsverfahren Anwendung findet, durch das die Variabilität der fünf Komponenten einer Stellung eines bewegbaren Elements reduziert oder gemindert werden kann, die hinsichtlich einer variablen Lastverteilung gemäß der Änderung der relativen Position eines Elements und einer Anzahl von Wälzkörpern die Genauigkeit eines Kugelspindelsystems darstellt.

In der Wälzkörperführungsvorrichtung sind die relativen Positionen der entsprechenden Wälzkörper und des bewegbaren Elements gemäß der Auslenkung variabel, wobei ein Zyklus vollzogen ist, wenn die Auslenkung den Wert 2 κDa erreicht (Wälzkörperhöhe oder Aufnahmehöhe), wonach dieser Zyklus wiederholt wird. Da sich die relativen Positionen der Wälzkörper in dem Intervall der 2 κDa Länge verändern, verändert sich die Lastverteilung in der Kugelspindel und daher die Stellung des Tischs des Wälzkörperführungssystems gemäß der Änderung dieser Lastverteilung.

Die Erfinder der vorliegenden Anmeldung analysierten die Genauigkeit eines linearen Wälzkörperführungssystems durch Unterteilen der 2 κDa Länge des bewegbaren Elements und durch Lösen der Gleichgewichtsgleichungen betreffend die externen Belastungen und die Belastungen des Wälzkörpers an entsprechenden Positionen, um dadurch fünf variable Komponenten der Stellung des Tisches zu erhalten. In dieser Analyse zeigte sich, dass es durch die Deformation eines Flanschabschnittes des bewegbaren Elementes möglich ist, die Genauigkeit effektiver zu analysieren.

Gemäß dem Ergebnis dieser Analyse hat man herausgefunden, dass sich mit einem Verringern des Durchmessers des Wälzkörpers die radiale Versetzung, die Kipp- und die maximale Lastverteilung verringern, wobei jedoch die radiale Versetzung und die die Genauigkeit des Wälzkörperführungssystems darstellende Kippwinkelvariation nicht direkt proportional zum Durchmesser des Wälzkörpers ist. D. h., dass herausgefunden worden ist, dass es einen anderen Faktor als den Durchmesser des Wälzkörpers geben muss, der einen Einfluss auf die Genauigkeit ausübt. Hinsichtlich dieses Faktors gaben die Erfinder ihr Augenmerk auf ein Verhältnis der Variation der Anzahl der belasteten Wälzkörper, die die Last in der 2 κDa Länge verteilen, und sie fanden heraus, dass die Variationen der radialen Versetzung und des Kippwinkels extrem gering gemacht werden können, indem dieses Verhältnis auf einen bestimmten Wert gesetzt wird, womit dadurch die Genauigkeit des linearen Führungssystems beträchtlich erhöht ist.

Unter Betrachtung der obigen Ausführungen können die Aufgaben der vorliegenden Erfindung gelöst werden, indem in einem Aspekt ein Verfahren zur Bestimmung der Länge einer Laufwegoberfläche eines bewegbaren Elements und eines Durchmessers eines Wälzkörpers einer Wälzkörperführungsvorrichtung vorgesehen ist, welche ein bewegbares Element und Wälzkörper aufweist, wobei in einer Länge von 2 κDa des bewegbaren Elements, innerhalb der relative Positionen des bewegbaren Elements und der entsprechenden Wälzkörper variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 100% bis 0% (100% : 0%) festgelegt ist, wobei $I = \mathrm{int}(2Ux/\kappa Da + 0{,}5)$, mit 2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

Gemäß diesem Aspekt der Erfindung ist die Veränderung der Anzahl der wirksamen Wälzkörper hinsichtlich der Auslenkungslänge reduziert, wobei die Genauigkeit des Wälzkörperführungssystem und insbesondere die Abwälzpräzision beträchtlich verbessert werden kann. Überdies ist bei einer Reduzierung der Veränderung der Anzahl der wirksamen Wälzkörper auch der Einfluss auf die Abwälzgenauigkeit durch eine Veränderung des Durchmessers des Wälzkörpers verringert, wobei beispielsweise der Durchmesser des Wälzkörpers unter Aufrechterhaltung der Abwälzgenauigkeit groß gewählt werden kann und überdies die grundlegende dynamische Belastungsrate ebenso groß gewählt werden kann.

Obige Aufgabe kann ebenso in einem anderen Aspekt gelöst werden, in dem ein Verfahren zur Bestimmung einer Länge einer Laufwegoberfläche eines bewegbaren Elements und eines Durchmessers eines Wälzkörpers einer Wälzkörperführungsvorrichtung bestimmt wird, die ein bewegbares Element und Wälzkörper aufweist, wobei in einer Wälzlänge von 2 κDa des bewegbaren Elements, innerhalb der relative Positionen des bewegbaren Elements und der entsprechenden Wälzkörper variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 50% bis 50% (50% : 50%) festgelegt ist, wobei I = int(2Ux/kDa + 0,5), mit 2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und κDa = Wälzkörperdurchmesser oder Aufnahmehöhe.

Gemäß diesem Aspekt kann die Genauigkeit des linearen Wälzkörperführungssystems, die Neigungswinkelgenauigkeit und die Radialgenauigkeit bedeutend verbessert werden.

In einem weiteren Aspekt kann die obige Aufgabe auch durch Vorsehen einer Wälzkörperführungsvorrichtung gelöst werden, die ein bewegbares Element und Wälzkörper aufweist, wobei die Länge einer Laufwegoberfläche des bewegbaren Elements und der Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Wälzkörper variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 100% bis 0% (100% : 0%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit 2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

In einem noch weiteren Aspekt kann die obige Aufgabe gelöst werden, indem eine Wälzkörperführungsvorrichtung vorgesehen ist, die ein bewegbares Element und Wälzkörper aufweist, wobei die Länge der Laufwegoberfläche des bewegbaren Elements und der Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 50% bis 50% (50% : 50%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit 2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

In einem noch weiteren Aspekt kann die obige Aufgabe gelöst werden, indem ein Wälzkörperführungssystem vorgesehen ist, das eine Spurschiene, mindestens ein auf der Spurschiene bewegbar befestigt bewegbares Element und Wälzkörper aufweist, die zwischen der Spurschiene und dem bewegbaren Element angeordnet sind, wobei die Länge einer Laufwegoberfläche des bewegbaren Elements und der Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Wälzkörper variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 100% bis 0% (100% : 0%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit 2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

In einem noch weiteren Aspekt kann obige Aufgabe gelöst werden, indem ein Wälzkörperführungssystem vorgesehen ist, das eine Spurschiene, mindestens ein auf der Spurschiene bewegbar befestigtes bewegbares Element und Wälzkörper aufweist, die zwischen der Spurschiene und den bewegbaren Elementen angeordnet sind, wobei die Länge einer Laufwegoberfläche des bewegbaren Elements und der Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 50% bis 50% (50% : 50%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit 2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

Die Erfinder gaben ihr Augenmerk überdies auf einen weiteren Faktor hinsichtlich der relativen Positionen der Wälzkörper in den bewegbaren Elementen, die an vorderen und hinteren Positionen in derselben Spurschiene des linearen Führungssystems angeordnet sind, und sie fanden heraus, dass die Variation des Neigungswinkels durch Einstellen der lichten Weite der bewegbaren Elemente beträchtlich reduziert werden kann, um so die relativen Positionen der Wälzkörper zueinander übereinstimmend vorzusehen.

D. h., dass obige Aufgabe gemäß der vorliegenden Erfindung hinsichtlich eines noch weiteren Aspektes gelöst werden kann, indem ein Wälzkörperführungssystem vorgesehen ist, das eine Schienenvorrichtung, eine Mehrzahl von bewegbaren Elementen, die auf der Schienenvorrichtung befestigt sind, und eine zwischen der Schienenvorrichtung und den bewegbaren Elementen angeordnete Wälzkörper aufweist, wobei die lichten Weiten der bewegbaren Elementen derart eingestellt sind, dass relative Positionen der Wälzkörper in den entsprechenden bewegbaren Elementen entsprechend übereinstimmen. Diese Einstellung wird dadurch realisiert, dass die lichte Weite des bewegbaren Elements ein ganzzahliges Vielfaches des Rollendurchmessers κDa ist.

Bei einem Aufbau, bei dem das Wälzkörperführungssystem mit einer Mehrzahl von Spurschienen versehen ist, kann die lichte Weite des bewegbaren Elements derart eingestellt sein, dass die relativen Positionen der Wälzkörper in den auf die entsprechenden Spurschienen befestigten bewegbaren Elementen einander entsprechen.

Überdies kann die vorliegende Erfindung die Kombination aus obigen zwei Faktoren (Aspekten) vorsehen, d. h., dass ein Wälzkörperführungssystem vorgesehen ist, bei dem eine Mehrzahl von bewegbaren Elementen auf der Schienenvorrichtung befestigt ist, wobei die Länge einer Laufwegoberfläche des bewegbaren Elements und der Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von κDa des bewegbaren Elements, in der relative Positionen des bewegbaren Elements und der entsprechenden Wälzkörper variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 100% bis 0% (100% : 0%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit 2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

Gemäß diesem Aspekt können die zwei obigen Wirkungen oder Funktionen wirksam kombiniert und die Genauigkeit des Wälzkörperführungssystems weiter erhöht werden.

Die Erfindung kann überdies die Kombination der zwei obigen Faktoren (Aspekte) vorsehen, d. h., dass ein Wälzkörperführungssystem vorgesehen ist, bei dem eine Mehrzahl von den bewegbaren Elementen auf der Schienenvorrichtung befestigt ist, wobei die Länge einer Laufwegoberfläche des bewegbaren Elements und der Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 50% bis 50% (50% : 50%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit 2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

Gemäß diesem Aspekt können die zwei obigen Wirkungen oder Funktionen ebenso wirksam kombiniert und die Genauigkeit des Wälzkörperführungssystems überdies erhöht werden.

Die weiteren charakteristischen Merkmale der vorliegenden Erfindung werden aus der mit auf Bezug auf die beigefügten Zeichnungen gemachten Beschreibung deutlicher.

Beschreibung von bevorzugten Ausführungsformen

Die vorliegende Erfindung wird nun nachfolgend mit Bezug auf die beigefügten Zeichnungen beschrieben.

Fig. 1 zeigt ein lineares Kugelführungssystem als ein Wälzkörperführungssystem, dessen Gegenstand hinsichtlich der vorliegenden Erfindung analysiert wurde, wobei dieses lineare Kugelführungssystem unter Zuständen mit unterschiedlichen schweren Belastungen, Kraftmomenten und dergleichen in einer Maschineneinrichtung, einer Transporteinrichtung, Industrierobotern und dergleichen verwendet wird.

Das in **Fig.** 1 gezeigte lineare Kugelführungssystem weist zwei Spurschienen **1** als parallel zueinander angeordnete Spurschafte und vier bewegbare Blöcke **2** (zwei für jede Spurschiene) als bewegbare Elemente auf, die mit den Spurschienen **1** zusammengesetzt sind und einen Tisch **3** tragen, der linear bewegt wird.

Fig. 2 zeigt eine lineare Kugelführung in Zusammenhang mit dem als Wälzkörperführungsvorrichtung in **Fig.** 1 gezeigten linearen Führungssystems. Diese lineare Kugelführung weist eine auf einem feststehenden Element (Teil) angeordnete Spurschiene **1**, die mit einer Kugellaufnut **1**a als Wälzkörperlauffläche entlang einer Längsrichtung der Schiene ausgebildet ist, einen bewegbaren Block **2**, der mit einem Kugelzirkulationsdurchgang **7** ausgebildet ist, der eine Lastlaufnut **2**a als eine Lastlauffläche entsprechend der Kugellaufnut **1**a der Spurschiene **1** hat und der mit der Spurschiene **1** zusammengesetzt ist, um zu dieser relativ beweglich zu sein, und eine Anzahl von Kugeln **4** als Wälzkörper auf, die in dem Kugelzirkulationsdurchgang **7** aufgenommen sind und darin gemäß der Relativbewegung des bewegbaren Blocks bezüglich der Spurschiene **1** zirkulieren.

Die Spurschiene **1** hat einen länglichen und einen schmalen Aufbau und weist eine im Wesentlichen rechteckige Form im Querschnitt auf. Die Kugellaufnuten **1**a sind an beiden Seitenflächen der Spurschiene **1** als Spuren für die Laufkugeln **4** ausgebildet, um sich so über die gesamte Längsrichtung der Spurschiene zu erstrecken. Obwohl die zwei Reihen der Kugellaufnuten **1**a an jeder Seitenfläche der Spurschiene **1** ausgebildet sind, können überdies die Anzahl und die Anordnung der Nuten **1**a gemäß den Aufgaben und den Anwendungsbedingungen verschiedenartig geändert werden. Die Spurschiene **1** ist mit Schraubenlöchern **5** zum Befestigen der Schiene **1** an einem feststehenden Abschnitt ausgebildet. Anstelle der gezeigten linearen Spurschiene **1** kann eine gekrümmte Schiene verwendet werden.

Der bewegbare Block **2** setzt sich aus einem Blockkörper **12** und einem Paar Endplatten **8** zusammen, die an beiden Längsenden des Blockkörpers **12** angeordnet und an diesem befestigt sind. Die Endplatte **8** ist mit einem Richtungswechseldurchgang ausgebildet und kann daher als richtungswechselndes Durchgangselement bezeichnet werden. Der Blockkörper **12** ist ein Blockelement mit einem ⊐-förmigen Querschnitt, der in einem zusammengesetzten Zustand einen der oberen Fläche der Spurschiene **1** zugewandten horizontalen Abschnitt **6**a und ein Paar Trägerschenkel **6**b hat, die Innenoberflächen aufweisen, die den Seitenflächen der Spurschiene **1** zugewandt sind. Jeder Trägerschenkel **6**b ist an seinen Innenflächen mit zwei Reihen Lastlaufnuten **2**a ausgebildet, die den an der Spurschiene **1** ausgebildeten Kugellaufnuten **1**a zugewandt sind. Überdies ist jeder Trägerschenkel **6**b mit zwei Kugelrückführdurchgängen **9** in der Form eines sich parallel zu den Kugellaufnuten **1**a erstreckenden Tunnels ausgebildet. Der Blockkörper **12** ist auch mit Schraubenlöchern **10** ausgebildet, um den Tisch **3** an der Oberfläche des Blockkörpers **12** mittels Schrauben oder dergleichen zu befestigen.

Gemäß der Bewegung des bewegbaren Blocks **6** entlang der Spurschiene **1** werden die Kugeln **4** entlang des Lastlaufdurchgangs bewegt und mit einer Last abgerollt, die von dem bewegbaren Block **6** aufgebracht wird, wobei die Kugeln **4** an ein Ende des Lastlaufdurchganges rollen und die Kugeln **4** dann nach oben gehoben und an den Rückführdurchgang **9** durch den Richtungswechseldurchgang geführt werden und danach an das eine Ende des Lastlaufdurchganges durch den anderen Richtungswechseldurchgang zurückgeführt werden.

Die Ausführung der Bewegung (des Laufs) des linearen Kugelführungssystems wird hierin unter der Annahme analysiert, dass ein lineares Kugelführungssystem an einem Maschinenwerkzeugtisch oder dergleichen angebracht ist, sowie in Betrachtung einer Deformation eines Flanschabschnittes des bewegbaren Blocks, wobei eine Gleichgewichtsgleichung hinsichtlich eines Lastverteilungszustandes in dem linearen Kugelführungssystems eingeführt wird, um damit die Beziehung zwischen einem Durchmesser des in der linearen Kugelführung aufgenommenen Kugel und einem Laufvorgang im Hinblick auf die Einflüsse der Steifheit und der Lebensdauer der Kugelführung klarzustellen.

Fig. 3 zeigt die Zustände, unter denen die Analysen vorgenommen wurden, wobei ein zu analysierender Gegenstand ein X-Tisch (einachsig) ist, bei dem vier bewegbare Blöcke durch zwei Schienen unterstützt sind. Zu **Fig.** 3 gehört die eine Draufsicht darstellende **Fig.** 3A, sowie die eine Seitenansicht darstellende **Fig.** 3B.

Mit Bezug zu **Fig.** 3:

Setzen der Koordinatenachsen: die X-Achse und Z-Achse liegen auf dem Tisch **3** und die Y-Achse ist in die zur Oberfläche des Tisches **3** senkrechte Achse gelegt.

Aufbringen einer äußeren Kraft: eine auf den Tisch **3** aufgebrachte radiale Last ist mit F_y bezeichnet; eine darauf aufgebrachte horizontale (transversale) Last ist mit F_z bezeichnet; eine um die X-Achse auftretende Abrollkraft ist mit M_c bezeichnet; eine um die Y-Achse auftretende Scherkraft ist mit M_b bezeichnet und eine Kippkraft um die Z-Achse ist mit M_a bezeichnet. Diese äußeren Kräfte wirken als statischer Äquivalenzbetrag auf den Ursprung der Koordinaten unterhalb des Zentralabschnitts des Tisches **3**.

Setzen einer Versetzung: eine radiale Versetzung des Tisches ist mit $\alpha1$ gekennzeichnet; seine horizontale Versetzung ist mit $\alpha4$; ein Abrollwinkel ist mit $\alpha3$ bezeichnet; ein Abrollwinkel ist mit $\alpha5$ bezeichnet; und ein Neigungswinkel ist mit $\alpha2$ bezeichnet.

Setzen der Tischposition: ein Abstand zwischen dem Endabschnitt der Spurschiene **1** zum Zentrum des Tisches ist mit l_{Start} bezeichnet.

Überdies sind die Bezeichnungen k1, k2, k3 und k4 jeweils den bewegbaren Blöcken zugeordnet, wobei die Montagenlängen des bewegbaren Blocks in der X-Richtung mit 2lx, und in der Z-Richtung mit 21z bezeichnet sind. Bezugszeichen von i = 1, i = 2, ... i = I sind den entsprechenden Kugeln **4** der linearen Kugelführung beigefügt, wobei Bezugszeichen von j = 1, j = 2, j = 3 und j = 4 zu den vier Lastlaufdurchgängen hinzugefügt sind, in denen die Kugeln angeordnet sind.

Fig. 4 zeigt einen Längsschnitt eines bestimmten bewegbaren Blocks **2** in einem bestimmten Zustand. Da sich eine hohe Hertzsche Pressung an den zwei Enden der Laufwegoberfläche des bewegbaren Blocks **2** mit entweder keiner Scheitelbombierung oder einer geringen Bombierung entwickelt, wenn die Kugeln den Durchgang passieren und dann an den Ausgang laufen, ist eine Scheitelbombierung vorzusehen, um diese Situation auszugleichen. In dem dargestellten Fall wird an beiden Endabschnitten des bewegbaren Blocks **2** eine kreisförmige R-Scheitelbombierung vorgenommen. Diese Scheitelbombierung wird in einem Abstand von der Endfläche des Führungsblocks zu einer Position $X\varepsilon$ mit einer durch einen Ausdruck $x = R(1 - \cos\theta)$ dargestellten Form ausgeführt. Da überdies der bewegbare Block von der Endfläche der Spurschiene **1** eingesetzt ist, wird die relative Position des bewegbaren Blocks **2** und der Kugel(n) **4** theoretisch durch den Abstand von der Schienenendfläche bestimmt.

Fig. 5 zeigt eine Beziehung zwischen der Wälzlänge des bewegbaren Blocks **2** und der Kugelposition. Wenn sich der bewegbare Block **2** bewegt, rollen die Kugeln **4**, wobei sich die relative Position des bewegbaren Blocks **2** zu den Kugeln **4** verändert. In dem dargestellten Beispiel verändert sich die relative Position des bewegbaren Blocks **2** zu den Kugeln gemäß der Darstellung in **Fig.** 5, wenn die Auslenkung des bewegbaren Blocks **2** von $0 \rightarrow 0{,}5\ \kappa Da \rightarrow 1{,}0\ \kappa Da \rightarrow 1{,}5\ \kappa Da \rightarrow 2{,}0\ \kappa Da$ verändert wird. Vorausgesetzt, dass der Kugeldurchmesser gleich κDa ist, wird bei einer Bewegung des bewegbaren Blocks **2** um 2 κDa ein anfänglicher Zustand eingenommen, der dem relativen Positionszustand des bewegbaren Blocks **2** und den Kugeln **4** in dem Fall der Auslenkung "0" entspricht. Das bedeutet, dass sich die relative Position des bewegbaren Blocks **2** und der Kugeln **4** mit 2 κDa des bewegbaren Blocks **2** in einem Zyklus verändert und dieser Zyklus darauffolgend wiederholt wird.

Dabei ist zu betonen, dass der Term "κ" aus κDa ein Vorfaktor und der Term "Da" den Kugeldurchmesser kennzeichnet. Der Vorfaktor "κ" ist einstimmig für eine Wälzkörperführungsvorrichtung bestimmt, die mit einem Aufnehmer versehen ist, wobei jedoch vorausgesetzt wird, dass der Vorfaktor auf "1" bezüglich des gesamten Kugelführungselements ohne Aufnehmer gesetzt wird und ein unbekannter Vorfaktor aufgrund der Erzeugung von Reibung zwischen den Kugeln in dem Lastlaufbereich wiederum angepasst werden muss. Die Verteilung des Vorfaktors "κ" wird experimentell durch Verwendung eines Kugeldurchlaufsensors oder dergleichen erhalten und auf die folgende Weise bestimmt.

Wälzkörperführungselement mit einem Aufnehmer:
κDa = Aufnehmerhöhe

Wälzkörperführungselement ohne Aufnehmer:
$\kappa Da = (1.000–1.005)\ Da$

Fig. 6 zeigt Zustände der Anzahl wirksamer Kugeln, die Kugeln sind, die die Laufwegoberfläche kontaktieren und eine aufgebrachte Last verteilen. Die Anzahl der wirksamen Kugeln wird erhalten, indem die Länge 2Ux der Schienenoberfläche durch die Kugeldurchmesser κDa dividiert und dann gerundet (Halb-Regelung) wird. **Fig.** 6A zeigt einen von einem Konstrukteur betrachteten Zustand der Anzahl von wirksamen Kugeln, wobei der Einfluss der Scheitelbombierung nicht miteinbezogen ist. Die konstruktive Anzahl wirksamer Kugeln beträgt $I = \mathrm{int}(2Ux/\kappa Da + 0{,}5)$, wobei "int" eine Funktion zum Weglassen der Ziffer hinter der ersten Dezimalstelle, 2Ux eine Länge einer Laufwegfläche eines bewegbaren Blocks und κDa eine Höhe des Wälzkörpers oder des Aufnehmers ist, und in diesem Fall $2Ux/\kappa Da$ abgerundet (Halb-Regelung) ist, da zu $2Ux/\kappa Da$ 0,5 addiert wird. **Fig.** 6B zeigt einen tatsächlichen Zustand, bei dem ausgehend von der Beziehung zwischen der Form der Scheitelbombierung und der elastischen Deformation der belasteten Kugeln die tatsächliche Länge des Kugelkontaktabschnittes 2Ux' ist, welche Länge kürzer als die Laufwegoberflächenlänge des bewegbaren Blocks 2Ux ist. Die tatsächliche Anzahl der wirksamen Kugeln ist ausgedrückt durch $I = \mathrm{int}(2Ux'/\kappa Da + 0{,}5)$, in der 2Ux' eine Länge einer Laufwegoberfläche des bewegbaren Blocks und κDa eine Höhe des Wälzkörpers oder Aufnehmers ist, und sich die Anzahl der wirksamen Kugeln innerhalb der Länge von 2 κDa beispielsweise mit I und I-1, und I' und I'-1 ändert.

Fig. 7 zeigt eine relative Beziehung zwischen der Spurschiene **1**, dem bewegbaren Block und den Kugeln **4**. Eine Bedienperson bestimmt eine Blockspannweite einer Mehrzahl von beweglichen Blöcken **2**, die auf der einzelnen Schiene befestigt sind. Im Allgemeinen sind die relativen Positionen der bewegbaren Blöcke **2** und der Kugeln **4** gemäß den entsprechenden bewegbaren Blöcken **2** unterschiedlich. D. h., dass gemäß **Fig.** 7, bei unterschiedlichen bewegbaren Blökken **2**, der Abstand lx01 zwischen einer Endfläche eines bewegbaren Blocks **2** (bei Draufsicht rechter Block) und der ersten Kugel **4** zu dem Abstand lx02 zwischen einer Endfläche eines anderen bewegbaren Blocks **2** (linker Block bei Draufsicht) unterschiedlich ist. Überdies variiert die Belastung, wobei sich demgemäß unter einer bestimmten Bedingung einer Belastung die Anzahl der wirksamen Kugeln **4** gemäß der Konstruktion von der tatsächlichen Anzahl derer für den entsprechenden bewegbaren Block **2** unterscheiden.

Fig. 8 zeigt die Lastverteilungen in den entsprechenden bewegbaren Blöcken **2**. Das Belastungsgleichgewicht in jedem der bewegbaren Blöcke **2** variiert von einem Moment auf den anderen gemäß der Positionsänderung der Kugeln **4** in jedem der bewegbaren Blöcke **2**. D. h., dass die Zustände der Lastverteilungen in den entsprechenden bewegbaren Blökken **2**, wenn der Tisch **3** in fünf Richtungskomponenten einer in einem bestimmten Moment verursachten Versetzung bewegt wird. Mit Bezug auf **Fig.** 8 bezeichnet ein Symbol Ab ein Krümmungszentrum der Lastrollnut **2**a des bewegbaren Blocks **2** und ein Symbol Ab' bezeichnet eine Position von Ab nach der Bewegung. Die Symbole $\delta yi2k$ und $\delta zi2k$ zeigen Komponenten in Y- und Z-Richtung des Bewegungsbetrages des Krümmungszentrums Ab. **Fig.** 8 zeigt den Zustand bei Betrachtung einer Fehlausrichtung, wobei ein Symbol Ar ein Krümmungszentrum der Kugelrollnut **1**a der Schiene **1** zeigt. Ein Symbol Ar' ist eine Position Ar nach der Bewegung. Die Symbole Δyil und Δzil zeigen Komponenten in Y- und Z-Richtung des Bewegungsbetrages des Krümmungszentrums Ar. Ein Symbol Vy zeigt eine Länge in Y-Richtung einer die Positionen Ab' und Ar' verbindenden Linie, und ein Symbol Vz zeigt eine Länge einer die Positionen Ab' und Ar' verbindenden Linie in Z-Richtung. Des Weiteren zeigt ein Symbol P_{ijk} eine Belastung des Wälzkörpers gemäß der Versetzung, welche Belastung in der Richtung der die Positionen Ab' und Ar' verbindenden Linie wirkt. Ein Winkel β_{ijk} ist ein durch die Richtung der Belastung Pijk mit der Horizontalebene festgelegter Winkel.

Überdies bezeichnet der Buchstabe "i" die Nummer des Wälzkörpers auf der Laufwegfläche, der Buchstabe "j" bezeichnet die Reihennummer des Wälzkörpers und der Buchstabe "k" bezeichnet die Nummer des Führungsblocks.

Fig. 9 zeigt einen deformierten Zustand des Blockflanschabschnittes (Flansch) **11**, wobei eine Trägertheorie auf die Deformation des Blockflansches **11** anwendbar ist. Ein rechteckiges Trägermodell wird durch Schneiden des Blockflanschs **11** hergestellt, so dass dessen Dicke dem Kugeldurchmesser entspricht, wobei der minimale Dicke-Abschnitt eines deformierten Flansches herausgenommen ist. Eine Trägerdeformation wird durch Verwendung der Lastverteilung (N = 1) im Voraus erhalten. Dann wird wiederum der Bewegungsbetrag des Krümmungszentrums Ab' der Nut in Abhängigkeit der Trägerdeformation erhalten, wobei die Lastverteilung an diesem bewegten Krümmungszentrum Ab' der Nut wiederum berechnet wird (N = 2). In diesem Fall, wenn die Differenz der Summe der Lastverteilungen aller Kugeln in den Fällen von N = 1 und N = 2 größer als 0,001 ist, wird wiederum eine Trägerdeformation erhalten und oben erwähnte Verfahren werden wiederholt. Eine Bedingung der Konvergenz dieser Lösung wird durch den folgenden Ausdruck ausgedrückt.

[Ausdruck 1]

Bedingung der Lösungskonvergenz

$$\sum_{k=1}^{4}\sum_{j=1}^{4}\sum_{i=1}^{I} P_{ijk}(N) - \sum_{k=1}^{4}\sum_{j=1}^{4}\sum_{i=1}^{I} P_{ijk}(N-1) < 10^{-3}$$

Die Bewegung des Tisches **3** hinsichtlich aller Auslenkungen kann durch Wiederholen obiger Berechnungsserien an der Position analysiert werden, an der die Länge unterteilt wird.

Hierunter wird ein Beziehungsausdruck der Lastverteilungstheorie erklärt, wobei hierin der Beziehungsausdruck durch Verwendung der fünf Variationskomponenten erhalten wird. Zunächst wird der folgende Berechnungsausdruck als ein Basisausdruck der obigen fünf Variationskomponenten festgelegt.

[Ausdruck 2]

Versetzung in Y-Richtung

$$\alpha_y = \alpha_1 + \alpha_{2x} + \alpha_{3z}$$

Versetzung in Z-Richtung

$$\alpha_z = \alpha_4 + \alpha_{5x} - \alpha 3_y$$

Die Hertzsche Elastizitätkontakttheorie (Hertzsches Gesetz) wird auf die elastische Deformation der Kugeln angewendet. Die Lastverteilung P_{ijk}, die elastische Versetzung δ_{ijk} und der Kontaktwinkel β_{ijk} werden mit der Hertzkonstante, dargestellt mit Cb, wie folgt ausgedrückt.

[Ausdruck 3]

$$\delta_{ijk} = \sqrt{V_y^{\,2} + V_z^{\,2}} - (2f-1)D_a + \lambda - \lambda_x$$

$$\tan\beta_{ijk} = \frac{V_y}{V_z}$$

Gemäß dieser Ausdrücke werden die folgenden fünf Bedingungsausdrücke zum Kräfteausgleich festgelegt.

[Ausdruck 4]

$$g_1 = \sum_{k=1}^{4}\sum_{j=1}^{4}\sum_{i=1}^{I} P_{ijk}\sin\beta_{ijk} - F_y = 0$$

für den Neigungswinkel:

$$g_2 = \sum_{k=1}^{4}\sum_{j=1}^{4}\sum_{i=1}^{I} P_{ijk}\sin\beta_{ijk}\,x_{ijk} - M_a = 0$$

für den Abrollwinkel:

$$g_3 = \sum_{k=1}^{4}\sum_{j=1}^{4} f_{ik} \sum_{i=1}^{I} P_{ijk}(z_{rijk}\sin\beta_{ijk} - y_{rijk}\cos\beta_{ijk}) - M_c = 0$$

wobei für f_{jk} gilt: $f_{1k} = f_{2k} = 1$, $f_{3k} = f_{4k} = -1$ mit Bezug auf die Spurschiene **1** und $f_{1k} = f_{2k} = -1$, $f_{3k} = f_{4k} = 1$ mit Bezug auf die Spurschiene **2**;
für die horizontale Versetzung:

$$g_4=\sum_{k=1}^{4}\sum_{j=1}^{4}\sum_{i=1}^{I} P_{ijk}\cos\beta_{ijk} - F_z = 0$$

für den Verdrehwinkel:

$$g_5=\sum_{k=1}^{4}\sum_{j=1}^{4}\sum_{i=1}^{I} P_{ijk}\cos\beta_{ijk}\, x_{ijk} - M_b = 0$$

Die fünf Variationskomponenten werden durch Lösen des obigen Gleichungssystems erhalten, wobei die Lösung durch das Newton-Raphson-Verfahren erhalten wird, das in **Fig.** 10 gezeigt ist.

Nachfolgend wird nun das Ergebnis der Analyse beschrieben.

Fig. 11 zeigt ein Analyseergebnis Nr. 1 "Einfluss durch Auslenkungslänge", wobei **Fig.** 11A ein eine Versetzung $\alpha 1$ in der vertikalen Richtung der Länge 4 κDa darstellender Graph, **Fig.** 11B ein den Neigungswinkel $\alpha 2$ darstellender Graph und **Fig.** 11C ein Graph ist, der die maximale Lastverteilung P_{ijkmax} für eine Kugel aufzeigt. Überdies sind als feste Bestandteile eine Form der Scheitelbombierung, eine Schienenspannweite, eine radiale Belastung und ein Vorlastbetrag ($\lambda = 0$) wie folgt festgelegt.

[Ausdruck 5]

$2\,l_z = 250$ mm "R" Bombierungsform
$F_y = 1000$ N $X_\varepsilon = 1.5 \times$ Da mm
$\lambda = 0$

$$\lambda_\varepsilon = \frac{Da}{500}\text{mm}$$

Überdies sind als variable Zustände eine Blocklänge und eine Blockspannweite auf die folgenden Zustände festgesetzt.

[Ausdruck 6]

2Ux = 80,4 mm
2lx = 250 mm

Es wurden fünf Arten von Kugeln mit fünf Arten von Durchmessern verwendet, von denen die Kugeln mit einem jeweiligen Durchmesser von 6,35000 mm als Basis (Bezug) verwendet wurden, und die anderen vier Arten von Kugeln jeweils einen Durchmesser hatten, der größer war als derjenige der Basiskugeln und zwei Durchmesser jeweils kleiner waren als derjenige der Basiskugel, wie das durch den JIS (Japanischen Industriestandart) festgelegt ist (d. h. fünf Arten von Kugeln wurden verwendet). Wie in **Fig.** 11 gezeigt, neigen die radiale Versetzung, der Neigungswinkel und die maximale Lastverteilung mit einer Abnahme des Kugeldurchmessers ebenso dazu abzunehmen. Die Kugeln mit einem Durchmesser von 5,55625 mm zeigten jedoch gute Fluktuationswerte des Neigungswinkels, der Versetzung in der vertikalen Richtung (radiale Versetzung) und der Variation der maximalen Lastverteilung, mehr als diejenigen Kugeln mit einem jeweiligen geringsten Durchmesser von 4,76250 mm. Es wird davon ausgegangen, dass das Ergebnis davon abhängt, ob diese Ausführungen eine direkte Proportionalität zu den Kugeldurchmessern haben oder andere Faktoren beteiligt sind, die dieses Ergebnis bewirken.

Fig. 12 zeigt den Graphen, der ein Analyseergebnis Nr. 2 "Fluktuation in Abhängigkeit des Kugeldurchmessers" darstellt, bei dem die Abszissenachse den Kugeldurchmesser und die Ordinatenachse die Fluktuationen der entsprechenden Werte aufzeigt. Aus diesem Graphen ist ebenso zu ersehen, dass diese Werte nicht direkt proportional zu den Kugeldurchmessern sind und eine unnatürliche Beziehung gegeben ist. Davon ausgehend wird erachtet, dass der Unterschied in den relativen Positionen der Kugeln **4** in den bewegbaren Blöcken **2**, die an der vorderen und hinteren Position in der Längsrichtung der Schiene **1** angeordnet sind, wie sie in dem vorigen Festlegungsverfahren festgelegt wurden, den diesen Einfluss ausmachenden Faktor darstellt.

Fig. 13 zeigt den Graphen, der ein Analyseergebnis Nr. 3 "Fluktuation in Abhängigkeit des Kugeldurchmessers im Falle koindizierender Phasen der bewegbaren Blöcke" darstellt, bei dem die Blockspannweiten so gewählt sind, dass die relative Position der Kugeln **4** in den bewegbaren Blöcken zur Deckung kommt, die an der längsseitigen vorderen und rückwärtigen Position angeordnet sind. Das Zusammenfallen der relativen Positionen der Kugeln **4** in den bewegbaren Blöcken **2** wird erhalten, in dem lx01 = lx02 gesetzt wird, wie das in **Fig.** 7 gezeigt ist. Da der bewegbare Block **2** auf der Spurschiene **1** von deren Endabschnitt angebracht wird, können die relativen Positionen der Kugeln **4** in den bewegbaren Blöcken einander koindizent vorgesehen werden, in dem die Blockspannweite 2lx als ein ganzzahliges Vielfaches von 2 κDa gewählt wird. Die Blockspannweite 2lx wird auf einen Wert nahe des ursprünglich gesetzten Wertes von 250 mm gesetzt. D. h., dass die variable Blockspannweite gemäß der folgenden Bedingungen gesetzt wird.

[Ausdruck 7]

2Ux = 80.4 mm
2lx = nl × 2 κDa mm (nl: integer)
lx01: = lx02
wobei nl ein Wert ist, bei dem sich 2lx 250 mm annähert.

Wie in **Fig.** 13 gezeigt, wird durch Vorsehen einer Koinzidenz der relativen Positionen der Kugeln **4** in dem vorderen (front-) und dem rückwärtigen (hinteren) bewegbaren Block **2** die Fluktuation des Neigungswinkels extrem gering (siehe Skalierung der Ordinatenachse). Die Größenordnung der Fluktuation ist jedoch nicht proportional zu dem Kugeldurchmesser und es scheint, dass noch ein anderer Faktor existiert.

Einer der anderen Faktoren, der in Betrachtung gezogen wird, ist ein Verhältnis der Variation der Anzahl der wirksamen Kugeln in der 2 κDa Länge. Das Verhältnis der Variation der Anzahl der wirksamen Kugeln fällt natürlich unterschiedlich aus, indem die Kugeldurchmesser gemäß der feststehenden Laufwegoberflächenlänge verändert werden. Durch Vereinheitlichung dieses Gegenstandes scheint es, dass demzufolge eine klarere Beziehung hervortritt.

Fig. 14 zeigt den ein Analyseergebnis Nr. 4 "Fluktuation in Abhängigkeit des Kugeldurchmessers" darstellenden Graphen, bei dem wie oben erwähnt, die Blockspannweiten so eingestellt sind, dass die relativen Positionen der Kugeln in dem vorderen und rückwärtigen bewegbaren Block zusammenfallen. Überdies ist die Länge der Laufwegoberfläche und der Kugeldurchmesser bestimmt, so dass ein Verhältnis, bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 50% bis 0% festgelegt ist. Das wird sowohl bei der theoretischen Anzahl von wirksamen Kugeln als auch bei deren tatsächlicher Anzahl bestimmt. D. h., dass die variablen Bedingungen auf die folgenden Werte gesetzt werden.

[Ausdruck 8]

$2Ux = ni \times \kappa Da$ mm (ni: optional)
$2lx = nl \times 2\,\kappa Da$ mm (nl: integer)
$lx01 := lx02$
mit ni ist ein Wert, bei dem sich 2Ux 80,4 mm annähert,
nl ist ein Wert, bei dem sich 2lx 250 mm annähert

ni ist ein Wert, so dass die theoretische Anzahl der wirksamen Kugeln I : I-1 = 50 : 50 wird, und die tatsächliche Anzahl der wirksamen Kugeln I' : I'-1 = 50 : 50 in der Länge von 2 κDa wird.

Wie in **Fig.** 14 gezeigt, zeigen der Kugeldurchmesser und die Fluktuationen der entsprechenden Werte eine im Wesentlichen proportionale Beziehung. Daraus wird geschlossen, dass die Phasen der Kugeln und das Verhältnis der Anzahl von wirksamen Kugeln in dem vorderen und dem hinteren Block derjenige Faktor ist, der die proportionale Beziehung des Kugeldurchmessers stört.

Fig. 15 zeigt den Graphen, der ein Analyseergebnis Nr. 5 "Fluktuation in Abhängigkeit des Kugeldurchmessers" darstellt, in dem die Analyseergebnisse Nr. 3 bis Nr. 5 in demselben Graphen beschrieben sind. Im Standardzustand (Standard), bei dem die Phasen der bewegbaren Blöcke **2** nicht miteinander koindizieren und das Verhältnis der Anzahl wirksamer Kugeln nicht festgelegt ist, ist die Fluktuation nicht proportional zu dem Kugeldurchmesser. Wenn die Phasen der bewegbaren Blöcke ($2lx = nlx \times \kappa Da$) koinzident gemacht sind, wird die Wälzgenauigkeit beträchtlich hoch und nahezu proportional zum Kugeldurchmesser. Wenn das Verhältnis der Variation der Anzahl wirksamer Kugeln zu dem entsprechenden Kugeldurchmesser (I : I-1 = 50 : 50, I' : I'-1 = 50 : 50) konstant gemacht wird, wird erstmals ein einfaches Verhältnis des Kugeldurchmessers vorgesehen.

Fig. 16 zeigt ein Analyseergebnis Nr. 6 "dynamischer Basisbelastungs-Nennwert in Abhängigkeit des Kugeldurchmessers", bei dem ein dynamischer Basisbelastungs-Nennwert in einem System gezeigt ist, das mit 4 Blöcken versehen ist. Der dynamische Basisbelastungs-Nennwert wurde gemäß dem folgenden Ausdruck berechnet.

[Ausdruck 9]

$$S_t = 2U_x$$

$$Q_{cg} = K_c(2U_x)^{-03}(2\kappa Da)^{1/3}$$

$$Q_{cr} = K_c\{\frac{18}{19}(2U_x)\}^{-0.3}(2\kappa Da)^{1/3}$$

$$C_{sys} = (2K)^{0.7}\ I\ \sin\beta(Q_{cg}^{-\frac{10}{3}} + Q_{cr}^{-\frac{10}{3}})^{-0.3}$$

mit:
Q_{cg} = Wälzelementbelastung (N) bezüglich einer gesamten Reihe eines Blocks;
Q_{cr} = Wälzelementbelastung (N) bezüglich einer gesamten Schiene;
C_{sys} = dynamischer Basisbelastungs-Nennwert des gesamten Systems;
K_c = Proportionalitätskonstante (bestimmt durch die Gestalt des Kontaktabschnitts);
I = theoretische Anzahl der wirksamen Kugeln
β = Kontaktwinkel (in deg Grad);
K = Anzahl der Blöcke (4).

Wie das aus **Fig.** 16 zu erkennen ist, wurde herausgefunden, dass die dynamische Belastungsrate einfach proportional zum Kugeldurchmesser ist.

Fig. 17 zeigt den ein Analyseergebnis Nr. 7 "Fluktuation in Abhängigkeit des Kugeldurchmessers" darstellenden Graphen, bei dem wie oben erwähnt, die Blockspannweiten angepasst sind, so dass die relative Position der Kugeln **4** jeweils in den bewegbaren Blöcken in der vorderen und rückwärtigen Längsrichtung zusammenfällt. Überdies ist die Länge der Laufwegoberfläche und der Kugeldurchmesser derart bestimmt, dass das Verhältnis, bei dem I die Anzahl der wirksamen

Kugeln und I-1 der Bereich der Anzahl der wirksamen Kugeln ist, bei einer 2 κDa-Länge, bei der die relative Position der entsprechenden Kugeln und der bewegbaren Blöcke variiert, mit ca. 100% : 0% festgelegt ist. Das wird sowohl hinsichtlich der theoretischen Anzahl wirksamer Kugeln als auch der tatsächlichen Anzahl derer bestimmt. D. h., dass variable Bedingungen auf die folgenden Werte gesetzt sind.

[Ausdruck 10]

$2Ux = ni \times \kappa Da$ mm (ni: optional)
$2lx = nl \times 2\ \kappa Da$ mm (nl: integer)
$lx01 := lx02$

ni ist ein Wert, bei dem in der Länge 2 κDa die theoretische Anzahl der wirksamen Kugeln I : I-1 = 50 : 50, I : I-1 = 100 : 0 wird und die tatsächliche Anzahl der wirksamen Kugeln I' : I'-1 = 50 : 50 und I' : I'-1 wird.

Wenn das Verhältnis wie in **Fig.** 17 gezeigt 100% : 0% ist, wird erachtet, dass die entsprechenden Fluktuationen proportional zum Kugeldurchmesser sind. Überdies kann die Fluktuation in dem Neigungswinkel dann extrem klein gemacht werden, wenn das Verhältnis, verglichen mit dem Verhältnis 50% : 0%, 100% : 0% ist.

Fig. 18 zeigt den ein Analyseergebnis Nr. 8 "Fluktuation in Abhängigkeit des Kugeldurchmessers" darstellenden Graphen, der einen Fall aufzeigt, der den Fall mit einem Verhältnis von I : I-1 = 100% : 0% des Analyseergebnisses Nr. 5 aus **Fig.** 15 überdeckt. Wie in **Fig.** 18 gezeigt, kann zunächst die Neigungsgenauigkeit insbesondere dadurch erhöht werden, dass die Phasen der bewegbaren Blöcke **2** zueinander koinzident (2lx = nlx κDa) gemacht sind. Indem das Verhältnis (I : I-1) der Variation der Anzahl an wirksamen Kugeln 50 : 50 gesetzt wird, kann die Neigungsgenauigkeit erhöht und ebenso die Steifigkeit in der Radialrichtung erhöht werden. Des Weiteren kann die Wälzgenauigkeit überdies erhöht werden, indem das Verhältnis (I : I-1) der Variation der Anzahl der wirksamen Kugeln auf 100 : 0 gesetzt wird.

Fig. 19 zeigt einen ein Analyseergebnis Nr.9 "dynamischer Basisbelastungs-Nennwert in Abhängigkeit des Kugeldurchmessers" darstellenden Graphen, wobei derselbe Berechnungsausdruck wie der für das Analyseergebnis Nr. 6 für den Berechnungsausdruck des dynamischen Basisbelastungs-Nennwerts verwendet wurde.

Die folgende Schlussfolgerung wird aus den obigen Analyseergebnissen Nr. 1 bis Nr. 9 erhalten.

Es wurde herausgefunden, dass die Genauigkeit und die Steifheit des linearen Kugelführungssystems im Fall einer vorbestimmten Blocklänge mit Verringerung des Kugeldurchmessers hoch wurden, in welchem System die Steifigkeit von der Versetzung $\alpha 1$ in der Vertikalrichtung angenommen wird und die Steifigkeit mit der Verringerung der Versetzung $\alpha 1$ erhöht wird. Der auf die Lebensdauer Einfluss ausübende dynamische Basisbelastungs-Nennwert kann mit Erhöhung des Kugeldurchmessers erweitert werden.

Überdies wurde befunden, dass ein Einfluss aufgrund der Differenz der relativen Positionen der Kugeln in den bewegbaren Blöcken in dem vorderen und hinteren bewegbaren Block beträchtlich groß ist.

Noch weiter wurde befunden, dass der Einfluss basierend auf dem Variationsverhältnis der Anzahl wirksamer Kugeln sehr hoch ist, die in der Länge variiert. Wenn die Variation der Anzahl wirksamer Kugeln aufgrund der Länge geringer wird (wenn (I : I-1) sich 100% : 0% annähert) verringert sich der Einfluss des Kugeldurchmessers auf die Auslenkgenauigkeit. Andererseits wird die Variation hoch (wenn (I : I-1) sich 50% : 50% annähert), wobei der Einfluss des Kugeldurchmessers auf die Fluktuation der Steifigkeit und der maximalen Lastverteilung gering wird.

Tatsächlich ist es jedoch schwierig, einfach zu sagen, dass durch Verringerung des Kugeldurchmessers die Funktion verbessert ist, weil die Blockspannweite durch eine Bedienperson festgelegt wird und die Länge der Laufwegfläche im Voraus bestimmt ist. Dann wird eine unmittelbare Anwendung der bestehenden Maschine durch eine minutiöse Einstellung der Blockspannweite durch eine Bedienperson ausgeführt. Wenn eine kleine spezielle Konstruktion für die bestehende Maschine erlaubt ist, kann die Scheitelbombierung durch Bestätigung der tatsächlichen Belastungsbedingung und durch Wählen eines optimalen Variationsverhältnis der Anzahl wirksamer Kugeln angepasst werden.

Die folgende Tabelle 1 zeigt Beispiele der Wälzkörperlänge κDa, der Länge 2Ux der Laufwegfläche (Block), der Blockspannweite 2lx und des dynamischen Basisbelastungs-Nennwertes C, in der "κ" auf κ = 1,003 und die Blocklänge 2Ux in Annäherung auf den oben erwähnten gesetzten Wert von 80,4 mm gesetzt ist. Indem die entsprechenden Zustände auf die in dieser Tabelle 1 gezeigten Werte gesetzt und bestimmt werden, ist es möglich, die Wälzgenauigkeit und die Genauigkeit in der Radialrichtung des linearen Kugelführungssystems zu erhöhen. Überdies ist zu beachten, dass die in dieser Tabelle 1 beschriebenen Werte lediglich Beispiele sind und viele andere Werte gewählt werden können, insoweit die vorigen erwähnten Ausdrücke erfüllt sind.

Tabelle 1

Überdies ist zu beachten, dass in den obigen Beschreibungen die vorliegende Erfindung nicht auf eine lineare Kugelführungsvorrichtung beschränkt ist, obwohl das lineare Kugelführungssystem als Gegenstand einer Analyse erklärt wurde, und sie kann bei einer Wälzkörperführungsvorrichtung angewendet werden, bei der Rollen als Wälzkörper verwendet werden. Andere Wälzkörperführungsvorrichtungen, die eine Kugelbüchse, eine Kugelspindel oder dergleichen verwenden, können ebenso verwendet werden. Noch weiter kann die vorliegende Erfindung auf eine Vorrichtung mit einer kurzen Aufnehmerstruktur angewendet werden, in der Wälzkörper nicht zirkulieren. Kurvenlineare Schienenelemente können anstelle der linearen Schienenelemente verwendet werden.

Patentansprüche

1. Verfahren zur Bestimmung der Länge einer Laufwegoberfläche eines bewegbaren Elements und eines Durchmessers eines Wälzkörpers einer Wälzkörperführungsvorrichtung, die ein bewegbares Element und Wälzkörper aufweist, wobei in einer Länge von 2 κDa des bewegbaren Elementes, in der relative Positionen des bewegbaren Elements und der entsprechenden Wälzkörper variieren, ein Verhältnis (I : I-1), in dem I die Anzahl wirksamer Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, im Bereich von ca. 100% bis 0% (100% : 0%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5) ist, mit
2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und
κDa = die Rollenkörper- oder Aufnehmerhöhe.
2. Verfahren zur Bestimmung einer Länge einer Laufwegoberfläche eines bewegbaren Elements und eines Durchmessers eines Wälzkörpers einer Wälzkörperführungsvorrichtung, die ein bewegbares Element und Wälzkörper aufweist, wobei wobei in einer Länge von 2κDa des bewegbaren Elementes, in der relative Positionen des bewegbaren Elements und der entsprechenden Wälzkörper variieren, ein Verhältnis (I : I-1), in dem I die Anzahl wirksamer Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, im Bereich von ca. 50% bis 50% (50% : 50%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5) ist, mit

2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und
κDa = die Rollenkörper- oder Aufnehmerhöhe.

3. Wälzkörperführungsvorrichtung, die ein bewegbares Element und Wälzkörper aufweist, wobei eine Länge einer Laufwegoberfläche des bewegbaren Elements und ein Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 100% bis 0% (100% : 0%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit
2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und
κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

4. Wälzkörperführungsvorrichtung, die ein bewegbares Element und Wälzkörper aufweist, wobei eine Länge einer Laufwegoberfläche des bewegbaren Elements und ein Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 50% bis 50% (50% : 50%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit
2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und
κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

5. Wälzkörperführungssystem, das eine Spurschiene, mindestens ein auf der Spurschiene bewegbar befestigtes bewegbares Element und Wälzkörper aufweist, die zwischen der Spurschiene und dem bewegbaren Element angeordnet sind, wobei eine Länge einer Laufwegoberfläche des bewegbaren Elements und ein Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2KDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 100% bis 0% (100% : 0%) festgelegt ist, wobei I = int (2Ux/κDa + 0,5), mit
2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und
κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

6. Wälzkörperführungssystem, das eine Spurschiene, mindestens ein auf der Spurschiene bewegbar befestigtes bewegbares Element und Wälzkörper aufweist, die zwischen der Spurschiene und dem bewegbaren Element angeordnet sind, wobei eine Länge einer Laufwegoberfläche des bewegbaren Elements und ein Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 50% bis 50% (50% : 50%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit
2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und
κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

7. Wälzkörperführungssystem, aufweisend eine Spurvorrichtung, eine Mehrzahl von auf der Spurvorrichtung befestigter bewegbarer Elemente und eine Anzahl von Wälzkörpern, die zwischen der Spurvorrichtung und den bewegbaren Elementen angeordnet sind, wobei die lichte Weite der bewegbaren Elemente derart gewählt ist, dass relative Positionen der Wälzkörper in den entsprechenden bewegbaren Elementen miteinander übereinstimmen.

8. Ein Wälzkörperführungssystem gemäß Anspruch 7, wobei die Spurvorrichtung eine Mehrzahl von Spurschaften aufweist, eine Mehrzahl von bewegbaren Elementen auf den entsprechenden Spurschaften befestigt sind, und die lichten Weiten der bewegbaren Elemente derart gewählt sind, dass relative Positionen der Wälzkörper in den bewegbaren Elementen, die auf den entsprechenden Spurschaften befestigt sind, miteinander übereinstimmen.

9. Ein Wälzkörperführungssystem gemäß Anspruch 7, wobei eine Länge einer Laufwegoberfläche des bewegbaren Elements und ein Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 100% bis 0% (100% : 0%) festgelegt ist, wobei I = int(2Ux/κDa + 0, 5), mit
2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und
κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

10. Ein Wälzkörperführungssystem gemäß Anspruch 7, wobei eine Länge einer Laufwegoberfläche des bewegbaren Elements und ein Durchmesser des Wälzkörpers derart bestimmt sind, dass in einer Länge von 2 κDa des bewegbaren Elements, in der die relativen Positionen des bewegbaren Elements und der entsprechenden Rollenelemente variieren, ein Verhältnis (I : I-1), bei dem I gleich der Anzahl der wirksamen Wälzkörper und I-1 ein Bereich der Anzahl der wirksamen Wälzkörper ist, innerhalb eines Bereiches von ca. 50% bis 0% (50% : 0%) festgelegt ist, wobei I = int(2Ux/κDa + 0,5), mit
2Ux = die Länge der Laufwegoberfläche des bewegbaren Elements und
κDa = der Wälzkörperdurchmesser oder die Aufnahmehöhe.

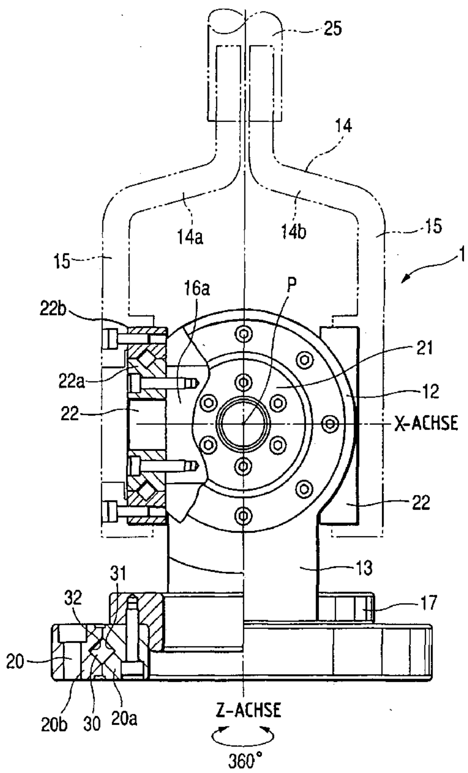
(54) Universalgelenk

(57) Ein Universalgelenk (11) ist mit einer Pendellager-Montageplatte (13) geformt, die ein gekrümmtes Joch (12) hat, einer Verbindung (14), die ein gekrümmtes Joch (15) hat, und einem kreuzförmigen Element (16), das kreuzförmige Schaftbereiche (16a und 16b) hat, die mit den jeweiligen Jochen (12 und 15) verbunden sind. Ein Y-Achsen-Pendellager (21) ist zwischen dem Joch (12) und dem Schaftbereich (16b) des kreuzförmigen Elements (16) vorgesehen, und ein X-Achsen-Pendellager (22) ist zwischen dem anderen Joch (15) und dem Schaftbereich (16a) davon vorgesehen. Da das Universalgelenk (11) drei Freiheitsgrade des Schwenkens hat, wird das Universalgelenk (11) stoßfrei und glatt betätigt, wenn die Position und Lage einer Gleitbasis in dem parallelen Verbindungsgliedmechanismus beispielsweise bestimmt sind.



DE 100 58 317 A 1

Beschreibung

HINTERGRUND DER ERFINDUNG

1. Gebiet der Erfindung

Die vorliegende Erfindung bezieht sich auf ein Universalgelenk, beispielsweise zur Verwendung in einem parallelen Verbindungsgliedmechanismus.

2. Beschreibung des Stands der Technik

Bislang ist ein paralleler Verbindungsgliedmechanismus bekannt, bei dem eine Vielzahl von Verbindungen zwischen einer Basis und einer schwankenden Basis besteht, so dass bewirkt wird, dass die schwankende Basis eine räumliche Bewegung ausführt. **Fig.** 15 zeigt einen Fahrsimulator, der solch einen parallelen Verbindungsmechanismus verwendet (siehe JP-A-11-224472, die durch die vorliegende Anmelderin vorgeschlagen worden ist). Stellglieder in der Form von sechs Verbindungen **3**, beispielsweise, sind zwischen der Basis **1** und der schwankenden Basis **2** angebracht, und eine schwankende Bewegung wird auf die schwankende Basis **2** auferlegt, wobei die dreidimensionale Position (räumliche Position) und die Lage der schwankenden Basis **2** geregelt werden, indem selektiv jedes der Stellglieder expandiert und kontraktiert wird. Zu dieser Zeit hat die schwankende Basis **2** sechs Freiheitsgrade, einschließlich drei Freiheitsgraden zur Bestimmung der Position der Stellglieder und drei Freiheitsgraden zum Bestimmen von deren Lage.

Als ein Gelenk **4**, das zwischen dem Ende jeder Verbindung **3** des parallelen Verbindungsgliedmechanismus und der Basis **1** oder der schwankenden Basis **2** gehalten werden muss, ist ein kugelförmiges Lager **5** bekannt, um die kugelförmige Bewegung der Verbindung **3** zu ermöglichen, oder ein Universalgelenk **6**, um zu ermöglichen, dass Kreuzwinkel der Verbindung **3** in bezug auf die Basis **1** oder die schwankende Basis **2** variiert werden können, wie es in **Fig.** 16 gezeigt ist.

Die kugelförmige Lagerung **5** ist eine Lagerung, um einen kugelförmigen Achszapfen **7** zu lagern, der an dem Endbereich der Verbindung **3** vorgesehen ist, und hat einen Freiheitsgrad von drei verschiedenen Drehbewegungen. Daher kann die kugelförmige Lagerung **5** stoßfrei betätigt werden, wenn die Position und Lage der schwankenden Basis **2** bestimmt sind.

Das Universalgelenk **6** hat zwei Freiheitsgrade des Schwenkens mit einem bekannten Mechanismus, der einen Gelenkkörper **9** umfasst, der ein Joch **8** hat, und ein metallisches Querpassstück **10**, wobei die Lagerung zwischen das Joch **8** und den Gelenkkörper **9** eingesetzt ist.

Der parallele Verbindungsgliedmechanismus ist jedoch strukturell durch die Tatsache charakterisiert, dass Lasten auf die Verbindungen axial auf die Gelenke **4** aufgebracht werden, und die Steifigkeit der kugelförmigen Lagerung **5** ist nicht ausreichend, um die axialen Lasten der Verbindungen **3** zu stützen. Obwohl es notwendig ist, dass der Auslenkwinkel α von jeder Verbindung **3** größer gemacht wird, um die Position und Lage der schwankenden Basis **2** in großem Maß zu variieren, wird bewirkt, dass die Verbindung **3** gegen die kugelförmige Lagerung **5** stößt im Fall, wenn die Lagerung eingesetzt wird, und dies macht es unmöglich, einen großen Auslenkwinkel α sicherzustellen.

In bezug auf das Universalgelenk **6**, da es nur zwei Freiheitsgrade des Schwenkens hat, obwohl der Schwenkwinkel α jeder Verbindung **3** vergrößert werden kann, ist es nicht in der Lage, stoßfrei betätigt zu werden, wenn die Position und Lage der schwankenden Basis **2** bestimmt sind, aufgrund einer nicht ausreichenden Freiheit zum Bestimmen der Position und Lage von sechs Freiheitsgraden der schwankenden Basis **2**.

ZUSAMMENFASSUNG DER ERFINDUNG

Eine Aufgabe der vorliegenden Erfindung angesichts der vorstehenden Probleme ist es, ein in hohem Maß steifes Universalgelenk zur Verwendung in einem parallelen Verbindungsgliedmechanismus vorzusehen, das nicht nur in der Lage ist, einen großen Auslenkwinkel für jede Verbindung sicherzustellen, sondern auch die axialen Lasten der Verbindung aufnehmen kann.

Die vorliegende Erfindung wird nun beschrieben. Obwohl Referenzziffern gemäß den beigefügten Zeichnungen angegeben sind, um das Verstehen der vorliegenden Erfindung zu erleichtern, ist die Erfindung nicht auf die Anordnung beschränkt, die in den Zeichnungen dargestellt ist.

Um die oben stehende Aufgabe zu erfüllen, ist gemäss einem ersten Aspekt der vorliegenden Erfindung ein Universalgelenk **11** vorgesehen, das gemäss einem Aspekt der Erfindung umfasst: eine erste drehbare Führungseinrichtung **20**, eine zweite drehbare Führungseinrichtung **21**, die drehbar durch die erste drehbare Führungseinrichtung **20** geführt wird, und eine dritte drehbare Führungseinrichtung **22**, die drehbar durch die zweite drehbare Führungseinrichtung **21** geführt wird, so dass das Universalgelenk drei Freiheitsgrade des Drehens insgesamt hat, wobei das Universalgelenk ein Paar von Gelenkkörpern **13**, **14** umfasst, die jeweils gegabelte Joche **12**, **15** haben, und ein kreuzförmiges Element **16**, das kreuzförmige Schaftbereiche **16**a, **16**b hat, die mit den jeweiligen Jochen **12**, **15** verbunden sind; wobei die zweite drehbare Führungseinrichtung **21** zwischen dem Joch **12** von einem Gelenkkörper **13** und dem Schaftbereich **16**b des kreuzförmigen Elements **16** vorgesehen ist; wobei die dritte drehbare Führungseinrichtung **22** zwischen dem Joch **15** des anderen Gelenkkörpers **14** und dem Schaftbereich **16**a vorgesehen ist, der den Schaftbereich **16**b des kreuzförmigen Elements **16** quert; und wobei die erste drehbare Führungseinrichtung **20** an einem des Paars von Gelenkkörpern **13**, **14** vorgesehen ist.

Gemäss der Erfindung wird, da das Universalgelenk **11** drei schwenkbare Freiheitsgrade hat, das Gelenk stoßfrei und glatt betätigt, so dass die Verbindung jede dreidimensionale Lage einnehmen kann, wenn die Position und Lage einer schwankenden Basis bestimmt sind. Da das Universalgelenk **11** im wesentlichen aus dem Paar von Gelenkkörpern **13**, **14** besteht, die jeweils die Joche **12**, **15** haben, und dem kreuzförmigen Element **16** zum Verbinden der Joche **12**, **15**, kann ein großer Auslenkwinkel des Paars der Gelenkkörper **13**, **14** sichergestellt werden, wodurch der Schwenkwinkel der Verbindung, beispielsweise in einem parallelen Verbindungsgliedmechanismus, vergrößerbar wird. In diesem Fall ist es nur notwendig, dass jede der drehbaren Führungseinrichtungen **20**, **21**, **22** einen Freiheitsgrad hat. Somit können Wälzlager, Gleitlager, Pendellager, gekrümmte Führungseinheiten und ähnliches beispielsweise verwendet werden.

Gemäss einem zweiten Aspekt der Erfindung hat bei dem Universalgelenk **11** des ersten Aspekts der Erfindung zumindest eine der ersten, zweiten und dritten drehbaren Führungseinrichtungen **20**, **21**, **22** einen äußeren Ring **20**b, der mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut **32** auf der inneren Umfangsseite der drehbaren Führungseinrichtung geformt ist; einen inneren Ring **20**a, der mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut **31** auf seiner äußeren Umfangsseite geformt ist, wobei der innere Ring **20**a in den äußeren Ring **20**b eingepasst ist; und eine Vielzahl von Walzen **33**, die zwischen diesen Walzentransfernuten **31**, **32** angeordnet sind und gehalten werden, so dass die Drehachsen von benachbarten Walzen einander senkrecht schneiden können.

Wenn eine axiale Last auf das Universalgelenk **11** von der Verbindung in dem parallelen Verbindungsgliedmechanismus beispielsweise aufgebracht wird, variiert der Schwenkwinkel der Verbindung, wodurch eine Last in Form einer Mischung aus radialen, Schub- und Drehmomentlasten auf jedes der Pendellager **20**, **21**, **22** des Universalgelenks **11** aufgebracht wird. Gemäss der Erfindung, da jedes der Pendellager **20**, **21**, **22** den äußeren Ring **20**b hat, der mit der im Querschnitt im wesentlichen V-förmigen Walzentransfernut **32** auf der inneren Umfangsseite der drehbaren Führungseinrichtung ausgestattet ist; den inneren Ring **20**a, der mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut **31** auf seiner äußeren Umfangsseite geformt ist, wobei der innere Ring **20**a in den äußeren Ring **20**b eingepasst wird; und die Vielzahl von Walzen **33**, die zwischen diesen Walzentransfernuten **31**, **32** angeordnet sind und gehalten werden, so dass die Drehachsen der benachbarten Walzen sich senkrecht schneiden können, wird ein in hohem Maß steifes Universalgelenk **11** erzielbar, das in der Lage ist, die Mischung von radialen, Schub- und Momentenlasten zu stützen, erzielbar. Zudem, da die Walze **33** die Wälzbewegung zwischen den Walzentransfernuten **31**, **32** macht, ist es nicht nötig, ein Spiel zwischen dem inneren und äußeren Ring **20**a, **20**b vorzusehen, wie in dem Fall, in dem bewirkt wird, dass eine Verschiebebewegung gemacht werden soll, und dies bewirkt, dass die verlangte Präzision direkt erreichbar ist. Der Reibwiderstand wird ebenfalls durch die Wälzbewegung reduziert, so dass ein Universalgelenk **11**, das die Abnutzung minimiert und kaum Wärme erzeugt, erzielbar ist.

Gemäss einem dritten Aspekt der Erfindung ist ein Universalgelenk **11** vorgesehen, das umfasst: ein Paar von Gelenkkörpern **13**, **14**, die jeweils gegabelte Joche **12**, **15** haben; ein kreuzförmiges Element **16**, das kreuzförmige Schaftbereiche **16**a, **16**b hat, die mit den jeweiligen Jochen **12**, **15** verbunden sind; und Lager **21**, **22**, die jeweils zwischen dem Joch **12** von einem Gelenkkörper **13** und dem Schaftbereich **16**b des kreuzförmigen Elements **16** und zwischen dem Joch **15** des anderen Gelenkkörpers **13** und dem Schaftbereich **16**a, der den Schaftbereich **16**b des kreuzförmigen Elements **16** schneidet, vorgesehen sind, wobei die Lager äußere Ringe **21**b, **22**b haben, die mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut auf der inneren Umfangsseite der drehbaren Führungseinrichtung geformt ist; innere Ringe **21**a, **22**a, die mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut auf ihrer äußeren Umfangsseite geformt sind, wobei die inneren Ringe **21**a, **22**a in die äußeren Ringe **21**b, **22**b eingepasst werden; und eine Vielzahl von Walzen, die zwischen diesen Walzentransfernuten angeordnet sind und gehalten werden, so dass die Drehachsen von aneinandergrenzenden Walzen sich senkrecht schneiden können. Somit wurden die vorstehenden Probleme gelöst.

Gemäss der Erfindung, da die Lager **21**, **22** des Universalgelenks **11** in der Lage sind, die radialen, Schub- und Momentenlasten aufzunehmen, wie es oben festgestellt wurde, ist ein Universalgelenk, das in der Lage ist, die axiale Last aufzunehmen, erzielbar.

Gemäss einem vierten Aspekt der Erfindung ist in einem Universalgelenk **11** gemäß dem ersten bis dritten Aspekt der Erfindung der Gelenkkörper **14** in zwei Teile **14**a, **14**b geteilt, und diese Teile, die so geteilt sind, werden unabhängig voneinander in bezug auf den Schaftbereich **16**a des kreuzförmigen Elements **16** verschwenkt.

Gemäss der Erfindung, wenn ein Paar von Verbindungen in parallelen Ebenen in einem parallelen Verbindungsgliedmechanismus schwenkt, der eine sechsschaftige Verbindung beispielsweise hat, können diese Verbindungen mit den jeweiligen geteilten Gelenkkörpern **14**a, **14**b verbunden werden zu der Zeit, zu der das Paar von Verbindungen innerhalb parallelen Ebenen schwenkt, wodurch die Anzahl von Universalgelenken **11**, die für den parallelen Verbindungsgliedmechanismus notwendig ist, verringerbar wird. Obwohl die Teilung als solche bewirkte, dass die Gelenkkörper **14**a, **14**b auskragen, wird die stoßfreie Verschwenkung der Gelenkkörper **14**a, **14**b durch ein schwenkbares Einpassen von innen in die drehbare Führungseinrichtung **22** kompensiert, die in der Lage ist, die Momentenlast aufzunehmen.

Gemäss einem fünften Aspekt der Erfindung ist ein Universalgelenk **41** vorgesehen, das umfasst: eine erste drehbare Führungseinrichtung **44** und eine zweite drehbare Führungseinrichtung **51**, **52**, die drehbar durch die erste drehbare Führungseinrichtung **44** geführt wird, wobei mindestens eine der ersten und zweiten drehbaren Führungseinrichtungen **44**, **51**, **53** gekrümmte Schienen **42** hat, die mit einer vorbestimmten Krümmung geformt sind, und Wälzkörpertransferflächen **42**a, **42**b entlang der längeren Richtung; eine Gleitbasis **53**, die mit einem unendlich umlaufenden Weg geformt ist, der die belasteten Wälzkörpertansferflächen **66**a, **66**b umfasst, die den Wälzkörpertansferflächen **66**a, **66**b entsprechen, und so hergestellt ist, dass er zu einer relativen, gekrümmten Bewegung in bezug auf die gekrümmten Schienen **42** in der Lage ist; und eine Vielzahl von Wälzkörpern **60**, die in der unendlichen, umlaufenden Bahn angeordnet sind und dort gehalten werden, und die dazu gebracht werden, umlaufend sich zu bewegen, wenn die gekrümmten Schienen **42** die relative, gekrümmte Bewegung in bezug auf die Gleitbasis **43** machen.

Gemäss der Erfindung, da die drehbare Führungseinrichtung **44** die gekrümmten Schienen **42** und die Gleitbasis **43** so über die Vielzahl von Wälzkörpern **60** hergestellt hat, dass sie zu der relativen, gekrümmten Bewegung in bezug auf die gekrümmten Schienen **42** in der Lage ist, ist ein in hohem Maß steifes Universalgelenk **41** erzielbar, das in der Lage ist, die Mischung von radialen, Schub- und Momentenlasten aufzunehmen. Weiterhin, da die Walze **60** die Wälzbewegung zwischen den Walzentransferflächen **42**a, **42**b und den belasteten Wälzkörpertansferflächen **66**a, **66**b macht, ist es nicht nötig, ein Spiel zwischen den gekrümmten Schienen **42** und der Gleitbasis **43** vorzusehen, und dies macht die verlangte Präzision direkt erreichbar. Der Reibwiderstand ist ebenfalls durch die Wälzbewegung reduziert, so dass ein Universalgelenk **11**, das die Abnutzung minimiert und kaum Wärme erzeugt, erzielbar ist.

In dem Fall des Universalgelenks **41**, das so angeordnet ist, ist es nicht nur auf das Universalgelenk für die parallelen Verbindungsglieder anwendbar, sondern auch als ein Universalgelenk, das in der Lage ist, eine Rotation zu übertragen, selbst wenn der Winkel, unter dem sich die zwei Achsen schneiden, frei variiert. Die Verwendung der gekrümmten Führungseinheit **44** macht das Universalgelenk **41** erzielbar, das in der Lage ist, die Rotation stabil zu übertragen, selbst wenn axiale Last aufgebracht wird.

Gemäss einem sechsten Aspekt der Erfindung ist ein Universalgelenk **41** vorgesehen, das umfasst: eine erste drehbare Führungseinrichtung **20**, eine zweite drehbare Führungseinrichtung **44**, die drehbar durch die erste drehbare Führungseinheit **20** geführt wird, und eine dritte drehbare Führungseinrichtung **51**, **52**, die drehbar durch die zweite drehbare Führungseinrichtung **44** geführt wird, wobei das Universalgelenk drei schwenkbare Freiheitsgrade insgesamt hat, wobei mindestens eine der ersten, zweiten und dritten drehbaren Führungseinrichtungen **20**, **44**, **51**, **52** gekrümmte

Schienen hat, die mit einer vorbestimmten Krümmung geformt sind, und Wälzkörpertansferflächen **42**a, **42**b entlang der längeren Richtung; eine Gleitbasis **43**, die mit einem unendlich umlaufenden Weg geformt ist, der belastete Wälzkörpertansferflächen **66**a, **66**b umfasst, die den Wälzkörpertansferflächen **42**a, **42**b entsprechen, und so hergestellt ist, dass er in der Lage ist, eine relative, gekrümmte Bewegung in bezug auf die gekrümmten Schienen auszuführen; und eine Vielzahl von Wälzkörpern **60**, die in dem unendlich umlaufenden Weg angeordnet und gehalten sind und dazu gebracht werden, sich auf einer umlaufenden Bahn zu bewegen, wenn die gekrümmten Schienen die relative, gekrümmte Bewegung in bezug auf die Gleitbasis **43** ausführen.

Gemäss der Erfindung, da das Universalgelenk **41** drei Freiheitsgrade des Schwenkens hat, wird das Gelenk stoßfrei und glatt betätigt, so dass die Verbindungen jede dreidimensionale Lage einnehmen können, wenn die Position und Lage der Gleitbasis bestimmt sind. Wie es oben bemerkt wurde, werden zudem die radialen, Schub- und Momentenlasten auf jede der drehbaren Führungseinrichtungen **20**, **44**, **51**, **52** des Universalgelenks **41** aufgebracht. Gemäss der Erfindung, da die drehbare Führungseinrichtung **44** die gekrümmten Schienen **42** und die Gleitbasis **43** so über die Vielzahl von Wälzkörpern **60** hergestellt hat, dass sie in der Lage zu der relativen, gekrümmten Bewegung in bezug auf die gekrümmten Schienen **42** ist, ist die drehbare Führungseinrichtung **44** in der Lage, die radialen, Schub- und Bewegungslasten aufzunehmen, wobei das Universalgelenk **41**, das zur Verwendung in dem parallelen Verbindungsgliedmechanismus passend ist, erzielbar ist. Weiterhin, da die Walze **60** die Wälzbewegung zwischen den Walzentransferflächen **42**a, **42**b und den belasteten Wälzkörpertansferflächen **66**a, **66**b macht, ist es nicht nötig, ein Spiel zwischen den gekrümmten Schienen **42** und der Gleitbasis **43** vorzusehen, und dies macht die verlangte Präzision auf direktem Weg erzielbar. Der Reibungswiderstand ist ebenfalls durch die Wälzbewegung reduziert, so dass ein Universalgelenk **41**, das die Abnutzung minimiert und kaum Wärme erzeugt, erzielbar ist.

Gemäss einem siebten Aspekt der Erfindung ist in dem Universalgelenk gemäss dem fünften Aspekt der Erfindung die erste drehbare Führungseinrichtung **44** mit den gekrümmten Schienen **42** versehen, die mit der vorbestimmten Krümmung gebildet sind, und den Wälzkörpertransferflächen **42**a, **42**b entlang der längeren Richtung; die Gleitbasis **43**, die mit dem unendlichen umlaufenden Weg einschließlich der belasteten Wälzkörpertransferflächen **66**a, **66**b, die den Wälzkörpertransferflächen **42**a, **42**b entsprechen, geformt ist und so hergestellt ist, dass sie in der Lage ist, eine relative, gekrümmte Bewegung in bezug auf die gekrümmten Schienen **42** auszuführen; und die Vielzahl von Wälzkörpern **60**, die in dem unendlich umlaufenden Weg angeordnet sind und gehalten werden und dazu gebracht werden, sich auf einer umlaufenden Bahn zu bewegen, wenn die gekrümmten Schienen die relative, gekrümmte Bewegung in bezug auf die Gleitbasis **43** machen; und die zweite drehbare Führungseinrichtung **51**, **52** ist auf der inneren Umfangsseite mit den gekrümmten Schienen versehen.

Gemäss der Erfindung macht die Anordnung der zweiten drehbaren Führungseinrichtung **51**, **52** innerhalb der gekrümmten Schienen das Universalgelenk **41** verkleinerbar ebenso wie sich erwiesen hat, dass die vorher erwähnte Arbeits/Betriebswirkung erzielbar ist.

Gemäss einem achten Aspekt der Erfindung sind bei dem Universalgelenk gemäss dem ersten bis siebten Aspekt der Erfindung die Drehachsen der drehbaren Führungseinrichtungen **20**, **21**, **22** einander unter rechten Winkeln kreuzend und weiterhin schneiden sich ihre Drehachsen gegenseitig in einem Punkt.

Gemäss der Erfindung können Variationen in der Lage von jeder Verbindung, die mit dem Universalgelenk verbunden ist, behandelt werden.

DETAILLIERTE BESCHREIBUNG DER BEVORZUGTEN AUSFÜHRUNGSFORMEN

Die vorliegende Erfindung wird nun im einzelnen unter Bezug auf die beigefügten Zeichnungen beschrieben.

Fig. 1 bis 3 zeigen ein Universalgelenk als eine erste Ausführungsform der Erfindung: **Fig.** 1 ist eine weitere Seitenansicht des Universalgelenks; **Fig.** 2 ist eine Seitenansicht davon; und **Fig.** 3 ist eine Draufsicht davon. Das Universalgelenk wird für einen parallelen Verbindungsgliedmechanismus mit einer Vielzahl von Verbindungen zwischen einer Basis und einer schwankenden Basis verwendet, wobei das Universalgelenk zwischen beiden Enden jeder Verbindung und der schwankenden Basis gehalten wird.

Wie es in **Fig.** 1 und 2 gezeigt ist, umfasst ein Universalgelenk **11** Z-Achsen-Pendellager **20** als eine erste drehbare Führungseinrichtung; Y-Achsen-Pendellager **21** als eine zweite drehbare Führungseinrichtung, die schwenkbar durch die Z-Achsen-Pendellager **20** geführt wird, und X-Achsen-Pendellager **22** als eine dritte schwenkbare Führungseinrichtung, die schwenkbar durch die Y-Achsen-Pendellager **21** geführt wird. Weiterhin ist das Universalgelenk **11** mit einer Pendellagermontageplatte **13** als ein Gelenkkörper geformt, die ein gegabeltes Joch **12** hat, einer Verbindung als dem anderen Gelenkkörper, der ein gegabeltes Joch **15** hat, und einem kreuzförmigen Element **16** (siehe **Fig.** 3), das kreuzförmige Schaftbereiche **16**a und **16**b hat, die mit den Jochen **12** und **15** zu verbinden sind. Das Z-Achsen-Pendellager **20** ist an dem unteren Ende der Pendellagermontageplatte **13** aufgepasst; das Y-Achsen-Pendellager **21** ist zwischen dem Joch **12** und dem koaxialen Schaftbereich **16**b des kreuzförmigen Elements **16** vorgesehen; und das X-Achsen-Pendellager **22** ist zwischen dem Joch **15** und dem koaxialen Schaftbereich **16**a des kreuzförmigen Elements **16** vorgesehen. Die Drehachsen der Pendellager kreuzen sich unter rechten Winkeln gegenseitig und zudem sind die X-, Y- und Z-Achsen so gerichtet, dass sie einander im Punkt P schneiden. Somit hat das Universalgelenk **11** drei Freiheitsgrade des Schwenkens insgesamt.

Wie es in **Fig.** 2 gezeigt ist, hat die Pendellagermontageplatte **13** das gegabelte Joch **12** an ihrer Seite des vorderen Endes und einen ringartigen Verbindungsbereich **17** an ihrer Basisseite, mit dem das Joch **12** verbunden ist. Der Verbindungsbereich **17** ist an dem inneren Ring **20**a des Z-Achsen-Pendellagers **20** befestigt. Der äußere Ring **20**b des Z-Achsen-Pendellagers **20** ist an der Basis des parallelen Verbindungsgliedmechanismus beispielsweise befestigt. Die Pendellagermontageplatte **13** ist um 360° um die Z-Achse schwenkbar in bezug auf die Basis angebracht.

Wie es in **Fig.** 3 gezeigt ist, hat das kreuzförmige Element **16** die Schaftbereiche **16**a und **16**b in der Gestalt eines Kreuzes angebracht. Der Schaftbereich **16**a entspricht mit seiner mittleren Achse der X-Achse, wohingegen der Schaftbereich **16**b mit seiner mittleren Achse der Y-Achse, senkrecht zur X-Achse, entspricht. Ein Paar von Y-Achsen-Pendellagern **21** ist zwischen dem Schaftbereich **16**b und dem Joch **12** vorgesehen. Wie es in **Fig.** 2 gezeigt ist, ist der innere Ring **21**a von jedem Y-Achsen-Pendellager **21** an dem Schaftbereich **16**b angebracht, wohingegen dessen äußerer Ring **21**b an dem Joch **12** befestigt ist. Weiterhin ist das kreuzförmige Element **16** schwenkbar auf der Y-Achse in bezug auf das Joch **12** eingerichtet.

Wie es in **Fig.** 1 gezeigt ist, hat eine Verbindung **14** ebenfalls ein gegabeltes Joch **15** an ihrer vorderen Endseite (der unteren Seite in **Fig.** 1) und einen Verbindungsbereich **25** zum Verbinden des Jochs mit seiner Basisbereichsseite (der oberen Seite darin). Ein Paar von X-Achsen-Pendellagern **22** ist zwischen dem kreuzförmigen Element **16** und dem Schaftbereich **16**a vorgesehen. Der innere Ring **22**a des X-Achsen-Pendellagers **22** ist an dem Schaftbereich **16**a befestigt, wohingegen der äußere Ring davon an dem Joch **15** befestigt ist. Weiterhin ist die Verbindung **14** schwenkbar auf der X-Achse in bezug auf das kreuzförmige Element **16** eingerichtet. Weiterhin kann die Verbindung **14** seitlich in zwei Teile geteilt sein. In diesem Fall sind die Verbindungen **14**a und **14**b, die von der Teilung in die zwei Teile resultieren, an den jeweiligen X-Achsen-Pendellagern **22** angepasst und schwenkbar um die X-Achse in bezug auf den Schaftbereich **16**a unabhängig voneinander (siehe **Fig.** 2).

Fig. 4 zeigt das Z-Achsen-Pendellager **20**. Da alle der Pendellager im wesentlichen die gleiche Konstruktion aufweisen, wird das Z-Achsen-Pendellager **20** als ein repräsentatives Beispiel beschrieben. Das Z-Achsen-Pendellager **20** hat den äußeren Ring **20** mit einer im Querschnitt im wesentlichen 90°-V-förmigen Walzentransfernut **32** auf seiner inneren Umfangsseite geformt, den inneren Ring **20**a in den äußeren Ring **20**b mit einer in im Querschnitt im wesentlichen 90°-V-förmigen Walzentransfernut **31** auf dessen äußerer Umfangsseite in den äußeren Ring **20**b eingepasst, und eine Vielzahl von Walzen **33**, die zwischen diesen Walzentransfernuten **31** und **32** angeordnet sind und dort gehalten werden (siehe **Fig.** 1).

Ein im Querschnitt im wesentlichen quadratischer Walzentransferweg ist mit den V-förmigen Walzentransfernuten **31** und **32** geformt, die in den jeweiligen äußeren und inneren Ringen **20**a und **20**b geformt sind. Die Vielzahl von Walzen **33** sind in dem Walzentransferweg angeordnet und werden dort gehalten, so das die Schwenkachsen von benachbarten sich unter rechten Winkeln treffen können. Ein Abstandshalter **34** zum Halten der Walzen **33** in der vorbestimmten Lage wird zwischen den benachbarten Walzenn **33** gehalten. In dem Walzentransferweg kreuzen sich die seitlich benachbarten Walzen **33** des Abstandshalters **34** und ihre Achsen unter rechten Winkeln und sind in nach außen und nach innen gerichtete Walzen **33**a und **33**b aufgeteilt. Die nach außen gerichtete Walze **33**a wird so gehalten, dass ihre Achse C so gehalten wird, dass sie auf das Drehzentrum B, das auf den Drehmittellinien des äußeren und inneren Rings **20**b und **20**a positioniert ist, gerichtet sein kann. Die nach innen gerichtete Walze **33**b wird ebenfalls so gehalten, dass ihre Achse D so ausgerichtet sein kann, dass sie auf das Drehzentrum A, das auf der Drehmittellinie davon positioniert ist, gerichtet ist. Wenn die Walzen **33**a und **33**b transferiert werden, wobei sie Lasten aufnehmen, werden die Achsen der Walzen **33**a, **33**b senkrecht zu dem verbindungsartigen Walzentransferweg gehalten, und jede der Walzen **33**a und **33**b wird transferiert, wobei sie ein gleichmäßiges Verschieben beibehält.

Da jedes Z-Achsen-Pendellager **20** so ist, dass die Drehachsen der benachbarten Walzen, die sich wechselweise unter rechten Winkeln treffen, in den 90° V-förmigen Walzentransfernuten **31** und **32**, wie es oben beschrieben wurde, angeordnet sind, kann es eine Last in jeder Richtung aufnehmen, wie eine radiale Last, eine Schub- und eine Momentenlast.

Fig. 5 bis 7 zeigen einen Zustand, in dem das Universalgelenk gedreht worden ist. **Fig.** 5 ist eine Seitenansicht, wobei das Universalgelenk um 60° um die Y-Achse geschwenkt ist; **Fig.** 6, eine Seitenansicht von **Fig.** 5; und **Fig.** 7 eine Draufsicht auf **Fig.** 5. Wie es in **Fig.** 5 gezeigt ist, wird der Pendellagermontageplatte **13**, die auf dem Z-Achsen-Pendellager montiert ist, gestattet, sich um 360° frei um die Z-Achse zu drehen. Weiterhin, da das Joch **12** der Pendellagermontageplatte **13** und das Joch **15** der Verbindung **14** durch das kreuzförmige Element **16** miteinander verbunden sind, ist es möglich, einen Schwenkwinkel auf der Y-Achse sicherzustellen und um die X-Achse bis zu ±60° zu drehen. Somit hat das Universalgelenk **11** drei Freiheitsgrade des Schwenkens um die X-, Y- und Z-Achse, wobei das Universalgelenk **11** stoßfrei und glatt betätigt wird, wenn die Position und Lage der schwankenden Basis des parallelen Verbindungsgliedmechanismus beispielsweise bestimmt sind. Weiterhin, da das Universalgelenk **11** einen großen Schwenkwinkel auf jeder der X-, Y- und Z-Achsen hat, ist die schwankende Basis fähig, sich in einem breiten Bereich zu bewegen. In dem parallelen Verbindungsgliedmechanismus, genau genommen, hat die schwankende Basis sechs Freiheitsgrade unter der Bedingung, dass das Universalgelenk an beiden Enden der Verbindungen insgesamt fünf Freiheitsgrade hat. Daher werden die Universalgelenke an beiden Enden der Verbindungen benötigt, um mindestens fünf Freiheitsgrade insgesamt zu haben, und in einem Fall, in dem das Universalgelenk auf der Basisseite drei Freiheitsgrade hat, muss das Universalgelenk auf der Seite der schwankenden Basis nur zwei Freiheitsgrade aufweisen.

Wenn eine axiale Last auf das Universalgelenk **11** von der Verbindung **14** aufgebracht wird, variiert der Schwenkwinkel der Verbindung **14**, wodurch eine Last als eine Mischung von radialen, Schub- und Momentenlasten auf jedes der Pendellager **20**, **21** und **22** des Universalgelenks **11** aufgebracht wird. Da jedoch jedes der Pendellager **20**, **21** und **22** wie oben erwähnt geformt ist, kann die Mischung der radialen, Schub- und Momentenlasten auf die Pendellager aufgebracht werden. Weiterhin, da die Walze **33** die Wälzbewegung zwischen den Walzentransfernuten **31** und **32** macht, ist es nicht nötig, ein Spiel zwischen dem inneren und äußeren Ring **20**a und **20**b vorzusehen, wie in dem Fall, in dem die Verschiebebewegung bewirkt wird, und dies macht die verlangte Präzision direkt erreichbar. Der Reibungswiderstand ist ebenfalls durch die Wälzbewegung reduziert, so dass ein Universalgelenk, das die Abnutzung minimiert, und kaum Wärme erzeugt, erreichbar ist.

Wenn ein Paar von Verbindungen in parallelen Ebenen in einem parallelen Verbindungsgliedmechanismus, der z. B. eine sechsschaftige Verbindung hat, schwenkt, kann jede Verbindung mit geteilten Verbindungen **14**a und **14**b verbunden sein, wenn das Paar von Verbindungen innerhalb paralleler Ebenen verschwenkt wird. In diesem Fall können zwei Verbindungen mit einem Universalgelenk **11** verbunden werden, wodurch die Anzahl von Universalgelenken **11**, die für den parallelen Verbindungsgliedmechanismus notwendig sind, verringerbar ist. Obwohl die geteilten Verbindungen **14**a und **14**b vorstehen sollen, wird das stoßfreie Verschwenken der Verbindungen **14**a und **14**b ausgeglichen, indem die Verbindungen an dem Pendellager, das in der Lage ist, die Momentenlast aufzunehmen, schwenkbar aufgepasst werden.

Fig. 8 bis 10 zeigen ein Universalgelenk **41** in einer zweiten Ausführungsform der Erfindung. **Fig.** 8 ist eine Seitenansicht des Universalgelenks **41**; **Fig.** 9 ist eine Seitenansicht aus **Fig.** 8; und **Fig.** 10 ist eine Draufsicht aus **Fig.** 8. Das Universalgelenk **41** hat ebenfalls drei drehbare Führungseinrichtungen, wie im Fall des Universalgelenks **11** in der ersten Ausführungsform der Erfindung, und drei Freiheitsgrade des Schwenkens. Die Drehachsen der jeweiligen drehbaren Führungseinrichtungen kreuzen sich gegenseitig unter rechten Winkeln und weiterhin sind die X-, Y- und Z-Achse so gerichtet, dass sie sich gegenseitig in einem Punkt P schneiden. Somit hat das Universalgelenk **14** insgesamt drei Freiheitsgrade des Schwenkens. Das Universalgelenk **41** unterscheidet sich von dem Universalgelenk **11** in der ersten Ausführungsform der Erfindung dahingehend, dass die zweite drehbare Führungseinrichtung mit gekrümmten Führungseinheiten **44** geformt ist, die gekrümmte Schienen und Gleitbasen **43** zum Durchführen einer gekrümmten Bewegung relativ zu den gekrümmten Schienen **42** hat. Um die Gesamtgröße des Universalgelenks **41** zu verringern, befindet sich die dritte drehbare Führungseinrichtung in den gekrümmten Schienen **41**. Die gekrümmte Führungseinheit **44**, als die zweite gekrümmte Führungseinrichtung, ist drehbar durch das Z-Achsen-Pendellager **20** als die erste drehbare Einrichtung geführt, und ein X-Achsen-Pendellager **46** als die dritte drehbare Führungseinrichtung ist schwenkbar durch die gekrümmte Führungseinheit **44** geführt.

Da das Z-Achsen-Pendellager **20** in der Konstruktion ähnlich dem Z-Achsen-Pendellager **20** der ersten Ausführungsform der Erfindung ist, sind gleiche Referenzziffern für die gleichen Bauteile des Pendellagers vergeben, wobei deren Beschreibung ausgelassen wird.

Ein Verbindungsring **45** ist an dem inneren Ring **20**a des Z-Achsen-Pendellagers **20** befestigt, und eine bogenförmige Montageplatte **48** für die Gleitbasis in einer Seitenansicht ist stehend in dem Verbindungsring **45** vorgesehen. Wie es in **Fig.** 9 gezeigt ist, ist ein Paar von gekrümmten Führungseinheiten **44** in die jeweils gegenüberliegenden inneren Wandoberflächen von den Pendellagermontageplatten eingepasst. Insbesondere ist die Gleitbasis **43** der gekrümmten Führungseinheit **44** an der Gleitbasismontageplatte **48** befestigt. Es sind eine Vielzahl von Gleitbasen vorgesehen, beispielsweise sind zwei Gleitbasen für die jeweiligen gekrümmten Schienen **42** vorgesehen. Ein Paar von gekrümmten Schienen ist durch eine Schienenmontageplatte **41** verbunden, so dass die gekrümmten Schienen **42** und die Schienenmontageplatte **49** die gekrümmte Bewegung auf der Y-Achse durchführen können.

Wie es in **Fig.** 8 gezeigt ist, ist ein Schaftbereich **50**, der sich in der Richtung der X-Achse erstreckt, an der Schienenmontageplatte **49** befestigt. Verbindungen **53**a und **53**b sind an dem Schaftbereich **50** über X-Achsen-Pendellager **51** und **52** angebracht, so dass sie axial Seite an Seite platziert sind. Zwei Schichten von im Querschnitt V-förmigen Walzentransfernuten sind auf dem äußeren Umfang eines im Durchmesser vergrößerten Orts in der Nähe der Mitte des Schaftbereichs **50** geformt, und innere Ringe **51**a und **52**a, die die X-Achsen-Pendellager **51** und **52** bilden, sind integral damit geformt. Äußere Ringe **51**b und **52**b, an denen V-förmige Walzentransfernuten auf der inneren Umfangsseite geformt sind, sind zusammenpassend mit den äußeren Umfängen der inneren Ringe **51**a und **52**a. Die Drehachsen von einer Vielzahl von benachbarten Walzen **54**, die sich wechselweise unter rechten Winkeln treffen, sind angeordnet und werden gehalten zwischen den Walzentransfernuten, wie es oben beschrieben worden ist. Die Verbindungen **53**a und **53**b können unabhängig voneinander, wie die Verbindungen **14**a und **14**b in der ersten Ausführungsform der Erfindung, gedreht werden oder integral gedreht werden.

Fig. 11 zeigt eine Anordnung im einzelnen von der gekrümmten Führungseinheit. In **Fig.** 11 bezeichnet Referenzziffer **42** bogenförmige, gekrümmte Schienen, die mit einer vorbestimmten Krümmung geformt sind; 43 Gleitbasen, die entlang der gekrümmten Schienen bewegbar sind. Es ist zu bemerken, dass obwohl die Gleitbasen in einer linearen Form gezeigt sind, sie tatsächlich gekrümmt sind.

Die gekrümmten Schienen **42** sind rechteckig im Querschnitt und vier der Kugeltransfernuten **42**a und **42**b als Wälzkörpertansferflächen zur Verwendung beim Transferieren von Kugeln **60** als Wälzkörper sind entlang der längeren Richtung geformt. Diese Kugeltransfernuten **42**a und **42**b sind auf beiden Seiten von jeder gekrümmten Schiene **42** geformt und an beiden Kantenbereichen von ihrer Oberfläche. Weiterhin sind die gekrümmten Schienen **42** mit Bolzenpasslöchern **61** in geeigneten Intervallen in der längeren Richtung geformt, und die gekrümmten Schienen **42** sind an der Schienenmontageplatte **49** mit Fixierbolzen (nicht gezeigt) befestigt, die in die Bolzenpasslöcher **61** eingeführt sind.

Die Gleitbasis **43** ist mit einem sich bewegenden Block **63** geformt, der Bohrungslöcher **62** hat, und ein Paar von Deckelkörpern **64** und **64**, die jeweils an beiden Kantenflächen in Längsrichtung des sich bewegenden Blocks befestigt sind, so dass ein unendlich umlaufender Weg für die Kugeln in der Gleitbasis **43** geformt wird, indem die Deckelkörper **64** an dem sich bewegenden Block **63** befestigt werden. Weiterhin ist ein Dichtelement **65**, das in einen verschiebbaren Kontakt mit den gekrümmten Schienen **42** gebracht ist, in die Deckelkörper **64** eingepasst, um zu verhindern, dass Staub und ähnliches, das an den gekrümmten Schienen **42** haftet, in die Gleitbasis **43** eindringt.

Der sich bewegende Block **63** ist mit einem horizontalen Bereich **63**a versehen, der mit einer Montagefläche geformt ist, und einem Paar von Randbereichen **63**b und **63**b, die von dem horizontalen Bereich **63**a hängen und im Querschnitt im wesentlichen sattelförmig sind. Weiterhin sind gekrümmte Lasttransfernuten **66**a und **66**b als Transferflächen von vier Lastwälzkörpern geformt, die in Richtung auf die jeweiligen Kugeltransfernuten **42**a und **42**b der gekrümmten Schienen **42** gerichtet sind, auf der unteren Oberflächenseite des horizontalen Bereichs **63**a und den inneren Oberflächenseiten der jeweiligen Randbereiche **63**b. Weiterhin sind Kugelrückkehrlöcher **67**a und **67**b, die den jeweiligen Lasttransfernuten **66**a und **66**b entsprechen, in dem horizontalen Bereich **63**a und den Randbereichen **63**b geformt. Die Lasttransfernuten **66**a und **66**b sind mit den entsprechenden Kugelrückkehrlöchern **67**a und **67**b durch einen U-förmigen, die Richtung ändernden Weg verbunden, der in den Deckelkörpern **64** geformt ist, wodurch der unendlich umlaufende Weg für die Kugeln gebildet wird.

Wenn die Kugeln **60**, die die Last zwischen den Kugeltransfernuten **42**a und **42**b der gekrümmten Schienen **42** verteilt haben und den Lasttransfernuten **66**a und **66**b des sich bewegenden Blocks **63**, die Transferbewegung durch die Lasttransfernuten **66**a und **66**n vervollständigt haben, wenn sich die Gleitbasis **43** bewegt, werden die Kugeln von der Last frei gegeben und dringen in den die Richtung ändernden Weg von einem der Deckelkörper **64** ein. Weiterhin machen die Kugeln **60**, die in dem Nichtlastzustand verbleiben, die Transferbewegung durch die Kugelrückkehrlöcher **67**a und **67**b des sich bewegenden Blocks **63** in einer Richtung entgegengesetzt zu der Transferrichtung in den Lasttransfernuten **66**a und **66**b. Weiterhin dringen die Kugeln **60**, die die Transferbewegung durch die Kugelrückkehrlöcher **67**a und **67**b vervollständigt haben, wer zwischen der gekrümmten Schiene und dem sich bewegenden Block **63** über den die Richtung ändernden Weg des anderen Deckelkörpers **64** ein und führen die Transferbewegung durch die Lasttransfernuten **66**a und **66**b aus, wobei sie die Last aufnehmen.

Kugelhalteplatten **68** sind an den unteren Enden der jeweiligen Randbereiche **63**b des sich bewegenden Blocks **63** montiert. Die Kugelhalteplatte **68** ist eine Metallplatte, die geformt wird, indem sie gepresst wird oder die aus hartem Kunstharz durch Spritzguss gefertigt wird, wodurch verhindert wird, dass die Kugeln **60**, die die Transferbewegung durch jede der Lasttransfernuten **66**a und **66**b machen, aus der Gleitbasis **63** rutschen, wenn die Gleitbasis **43** von den gekrümmten Schienen **42** entfernt wird.

Fig. 12 und 13 zeigen die Schwenkwinkel um die X-, Y- und Z-Achsen des Universalgelenks **41**. **Fig.** 12 zeigt einen Zustand, in dem die Verbindungen **53**a und **53**b um 60° um die Y-Achse verschwenkt sind; und **Fig.** 13 zeigt eine Seitenansicht aus **Fig.** 12. Da die gekrümmte Führungseinheit **44** auf dem Z-Achsen-Pendellager **20** montiert ist, wie es in **Fig.** 12 gezeigt ist, ist sie um 360° um die Z-Achse schwenkbar. Die X-Achsen-Pendellager **51** und **52** sind an den gekrümmten Schienen **42** angepasst, und da die gekrümmten Schienen **42** in bezug auf die Gleitbasis **43** gedreht werden, sind die X-Achsen-Pendellager **51** und **52** um die Y-Achse bis zu ±60° schwenkbar. Wie es in **Fig.** 13 weiterhin gezeigt ist, sind die Verbindungen an dem Schaftbereich **50** über die X-Achsen-Pendellager **51** und **52** befestigt, wodurch die Verbindungen um die X-Achse bis zu ±60° verschwenkt werden. Somit ist es möglich, obwohl die drehbare Führungseinheit mit der gekrümmten Führungseinheit **55** geformt ist, den Schwenkwinkel auf jeder Achse ausreichend größer als in dem Universalgelenk **11** in der ersten Ausführungsform der Erfindung zu machen.

In dem Universalgelenk **41** gemäss dieser Ausführungsform der Erfindung wird die zweite drehbare Führungseinheit hergestellt, indem die Vielzahl von Kugeln **60** in bezug auf die gekrümmten Schienen **42** zusammen mit der Gleitbasis **43** verwendet werden, die die relative, gekrümmte Bewegung ausführt, so dass sie die radialen, Schub- und Momentenlasten aufnehmen können. Somit ist ein Universalgelenk **41**, das zur Verwendung in dem parallelen Verbindungsgliedmechanismus passend ist, erreichbar. Da die Kugeln **60** die Wälzbewegung zwischen den Kugeltransfernuten **42**a und **42**b der gekrümmten Schienen **42** und den Lasttransfernuten **66**a und **66**b der Gleitbasis **43** machen, ist es nicht notwendig, ein Spiel zwischen den gekrümmten Schienen **42** und der Gleitbasis vorzusehen, und dies macht es möglich, dass die verlangte Präzision direkt erreichbar ist. Weiterhin wird der Reibungswiderstand ebenfalls durch die Wälzbewegung reduziert und folglich ist ein Universalgelenk, das die Abnutzung minimiert und kaum Wärme erzeugt, erzielbar.

Obwohl die Beschreibung von dem Fall gegeben worden ist, in dem das Universalgelenk **41** verwendet wird, das die drei Freiheitsgrade hat, für den parallelen Verbindungsgliedmechanismus in der zweiten Ausführungsform der Erfindung, ist solch ein Universalgelenk **41** auch für das zu verwenden, was in der Lage ist, eine Rotation zu übertragen, selbst wenn der Winkel, unter dem die zwei Achsen des Universalgelenks sind, frei variiert. In diesem Fall ist es möglich, ein Universalgelenk zu erzielen, das in der Lage ist, eine Rotation stabil zu übertragen, selbst wenn eine axiale Last darauf aufgebracht wird, indem das Universalgelenk nur mit der gekrümmten Führungseinheit **44** und den X-Achsen-Pendellagern **51** und **52** geformt wird, ohne das Z-Achsen-Pendellager **20** zu verwenden, wobei ein Eingangsschaft mit der Seite der Gleitbasenmontageplatte **48** verbunden wird und ein Ausgangsschaft an der Seite der Verbindungen **53**a und **53**b angebracht wird.

Fig. 14 zeigt ein Universalgelenk **71** in einer dritten Ausführungsform der Erfindung. Obwohl das Universalgelenk **71** im wesentlichen gleich in der Konstruktion mit dem Universalgelenk **41** in der zweiten Ausführungsform der Erfindung ist, unterscheidet sich das erstere von dem letzteren in der Länge der gekrümmten Schienen **72** der gekrümmten Führungseinheit **74** und dem Abstand zwischen den Gleitbasen **43**. Die gekrümmten Schienen **72** sind kürzer gemacht als die gekrümmten Schienen **42** in der zweiten Ausführungsform der Erfindung und halbkreisförmig, um den Raum zu verringern. Weiterhin ist der Abstand zwischen den Gleitbasen ebenfalls kürzer, um den Schwenkwinkel des X-Achsen-Pendellagers bis zu ±60° sicherzustellen, obwohl die Breite der gekrümmten Schiene kürzer gemacht wird. Da die verbleibende Anordnung ähnlich zu derjenigen des Universalgelenks **41** in der zweiten Ausführungsform der Erfindung ist, sind gleiche Referenzziffern denselben Komponententeilen in der zweiten Ausführungsform gegeben, wobei deren Beschreibung ausgelassen wird.

Obwohl die Universalgelenke **11**, **41** und **71** auf den parallelen Verbindungsgliedmechanismus aufgebracht werden, wie es in der ersten bis dritten Ausführungsform der Erfindung beschrieben worden ist, sind die Universalgelenke **11**, **41** und **71** gemäss der Erfindung nicht nur auf den parallelen Verbindungsgliedmechanismus anwendbar, sondern auch auf verschiedene andere Mechanismen, solange diese anderen Mechanismen so sind, dass eine Vielzahl von Freiheitsgraden des Schwenkens für solche Universalgelenke **11**, **41** und **71** verlangt wird.

Wie es oben erläutert wurde, wird gemäss der Erfindung, da das Universalgelenk drei Freiheitsgrade des Schwenkens hat, das Universalgelenk stoßfrei und glatt betätigt, wenn die Position und Lage in dem parallelen Verbindungsgliedmechanismus beispielsweise festgelegt sind.

Da das Universalgelenk mit dem Paar von Verbindungskörpern geformt ist, die jeweils die gegabelten Joche haben, kann weiterhin ein großer Auslenkwinkel von dem Paar von

Verbindungskörpern sichergestellt werden, wodurch der Schwenkwinkel der Verbindung in dem parallelen Verbindungsgliedmechanismus beispielsweise vergrößerbar wird.

Weiterhin, da die schwenkbare Führungseinrichtung den äußeren Ring mit den im Querschnitt im wesentlichen V-förmigen Walzentransfernuten auf der inneren Umfangsseite der schwenkbaren Führungseinrichtung hat; den inneren Ring mit den im Querschnitt im wesentlichen V-förmigen Walzentransfernuten auf der äußeren Umfangsseite davon hat, wobei der innere Ring in den äußeren Ring eingepasst ist; und die Vielzahl von Walzen, die zwischen diesen Walzentransfernuten angeordnet sind und gehalten werden, so dass die Schwenkachsen der benachbarten sich senkrecht gegenseitig schneiden können, ist solch ein Universalgelenk in der Lage, die Mischung von radialen, Schub- und Momentenlasten aufzunehmen.

Patentansprüche

1. Universalgelenk, umfassend:
eine erste drehbare Führungseinrichtung;
eine zweite drehbare Führungseinrichtung, die drehbar durch die erste drehbare Führungseinrichtung geführt wird; und
eine dritte drehbare Führungseinrichtung, die drehbar durch die zweite drehbare Führungseinrichtung geführt wird, wobei das Universalgelenk drei Freiheitsgrade des Schwenkens insgesamt hat;
wobei das Universalgelenk ein Paar von Gelenkkörpern umfasst, die jeweils gegabelte Joche haben, und ein kreuzförmige Element, das kreuzförmige Schaftbereiche hat, die mit den jeweiligen Jochen verbunden sind; die zweite drehbare Führungseinrichtung zwischen dem Joch von einem Gelenkkörper und dem Schaftbereich des kreuzförmigen Elements vorgesehen ist; die dritte drehbare Führungseinrichtung zwischen dem Joch des anderen Gelenkkörpers und dem Schaftbereich vorgesehen ist, der den Schaftbereich des kreuzförmigen Elements schneidet; und die erste drehbare Führungseinrichtung an einem von dem Paar von Gelenkkörpern vorgesehen ist.

2. Universalgelenk nach Anspruch 1, wobei mindestens eine der ersten, zweiten und dritten drehbaren Führungseinrichtung einen äußeren Ring hat, der mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut auf der inneren Umfangsseite der drehbaren Führungseinrichtung geformt ist; einen inneren Ring, der mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut auf seiner äußeren Umfangsseite geformt ist, wobei der innere Ring in den äußeren Ring eingepasst ist; und eine Vielzahl von Walzen, die zwischen diesen Walzentransfernuten angeordnet sind und gehalten werden, so dass die Drehachsen der benachbarten Walzen einander senkrecht schneiden.

3. Universalgelenk, umfassend: ein Paar von Gelenkkörpern, die jeweils gegabelte Joche haben;
ein kreuzförmiges Element, das kreuzförmige Schaftbereiche hat, die mit den jeweiligen Jochen verbunden sind; und
Lager, die jeweils zwischen dem Joch von einem Gelenkkörper und dem Schaftbereich des kreuzförmigen Elements und zwischen dem Joch des anderen Gelenkkörpers und dem Schaftbereich, der den Schaftbereich des kreuzförmigen Elements schneidet, vorgesehen sind;
wobei die Lager äußere Ringe haben, die mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut auf der inneren Umfangsseite der drehbaren Führungseinrichtung geformt sind; innere Ringe, die mit einer im Querschnitt im wesentlichen V-förmigen Walzentransfernut auf ihrer äußeren Umfangsseite geformt sind, wobei der innere Ring in den äußeren Ring eingepasst ist; und eine Vielzahl von Walzen, die zwischen diesen Walzentransfernuten angeordnet sind und gehalten werden, so dass die Drehachsen der benachbarten Walzen einander senkrecht schneiden können.

4. Universalgelenk nach Anspruch 1, wobei der Gelenkkörper in zwei Teile geteilt ist und diese so geteilten Teile unabhängig voneinander in bezug auf den Schaftbereich des kreuzförmigen Elements verschwenkt werden.

5. Universalgelenk, umfassend:
eine erste drehbare Führungseinrichtung; und
eine zweite drehbare Führungseinrichtung, die drehbar durch die erste drehbare Führungseinrichtung geführt wird;
wobei zumindest eine der ersten und zweiten drehbaren Führungseinrichtungen gekrümmte Schienen hat, die mit einer vorbestimmten Krümmung geformt sind und Wälzkörpertransferflächen entlang der längeren Richtung; eine Gleitbasis, die mit einem unendlich umlaufenden Weg geformt ist, einschließlich belasteten Wälzkörpertransferflächen, die den Wälzkörpertransferflächen entsprechen, und so hergestellt ist, dass sie eine relative, gekrümmte Bewegung in bezug auf die gekrümmten Schienen durchführen kann; und eine Vielzahl von Wälzkörpern, die angeordnet sind und gehalten werden in dem unendlich umlaufenden Weg und dazu gebracht werden, sich auf einer umlaufenden Bahn zu bewegen, wenn die gekrümmten Schienen die gekrümmte Relativbewegung in bezug auf die Gleitbasis durchführen.

6. Universalgelenk, umfassend:
eine erste drehbare Führungseinrichtung;
eine zweite drehbare Führungseinrichtung, die drehbar durch die erste drehbare Führungseinrichtung geführt wird; und
eine dritte drehbare Führungseinrichtung, die drehbar durch die zweite drehbare Führungseinrichtung geführt wird, wobei das Universalgelenk drei Freiheitsgrade des Schwenkens insgesamt hat;
wobei zumindest eine der ersten, zweiten und dritten drehbaren Führungseinrichtungen gekrümmte Schienen hat, die mit einer vorbestimmten Krümmung geformt sind, und Wälzkörpertransferflächen entlang der längeren Richtung; eine Gleitbasis, die mit einem unendlich umlaufenden Weg einschließlich belasteten Wälzkörpertransferflächen geformt ist, die den Wälzkörpertransferflächen entsprechen, und so hergestellt ist, dass sie eine gekrümmte Relativbewegung in bezug auf die gekrümmten Schienen durchführen kann; und eine Vielzahl von Wälzkörpern, die in der unendlich umlaufenden Bahn angeordnet sind und gehalten werden und dazu gebracht werden, sich auf der umlaufenden Bahn zu bewegen, wenn die gekrümmten Schienen die gekrümmte Relativbewegung in bezug auf die Gleitbasis machen.

7. Universalgelenk nach Anspruch 5, wobei die erste drehbare Führungseinrichtung die gekrümmten Schienen hat, die mit der vorbestimmten Krümmung geformt sind, und Wälzkörpertransferflächen entlang der längeren Richtung; die Gleitbasis, die mit dem unendlichen kreisförmigen Weg geformt ist, einschließlich der belasteten Wälzkörpertransferflächen, die den Wälzkörpertransferflächen entsprechen, und so herge-

stellt ist, dass sie in der Lage ist, die gekrümmte Relativbewegung in bezug auf die gekrümmten Schienen durchzuführen; und eine Vielzahl von Wälzkörpern, die in dem unendlich umlaufenden Weg angeordnet sind und gehalten werden und dazu gebracht werden, sich auf der umlaufenden Bahn zu bewegen, wenn die gekrümmte Schiene die gekrümmte Relativbewegung in bezug auf die Gleitbasis ausführt; und wobei die zweite drehbare Führungseinrichtung auf der inneren Umfangsseite der gekrümmten Schienen vorgesehen ist.

8. Universalgelenk nach einem der Ansprüche 1 bis 7, wobei die Drehachsen der drehbaren Führungseinrichtungen sich unter rechten Winkeln gegenseitig schneiden und weiterhin die Drehachsen sich gegenseitig in einem Punkt schneiden.

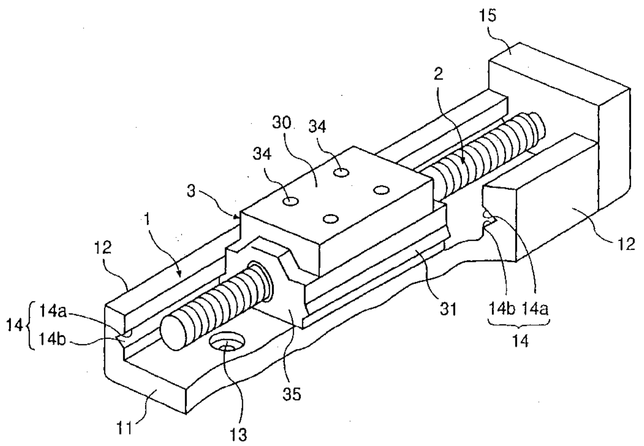
(54) Gleitführungseinheit

(57) Durch die vorliegende Erfindung wird eine Gleitführungseinheit bereitgestellt, wobei ein Mutterelement zum Ausüben einer Antriebskraft auf ein Gleitelement und ein Gleitkontaktelement zum Halten des Gleitelementes in Bewegung bezüglich der Laufschiene am Gleitelement stabil befestigt sind, und die auf einfache Weise und kostengünstig ohne eine erhöhte Anzahl von Komponenten herstellbar ist. Das erfindungsgemäße Gleitführungselement ist dadurch gekennzeichnet, daß das Gleitelement aus einem Metallkern mit einer Montagefläche für einen beweglichen Körper und einem durch Gießen um den Kernblock herum ausgebildeten Harzabschnitt besteht, und dadurch, daß das mit der Laufschiene in Gleitkontakt stehende Gleitkontaktelement und der Mutterabschnitt, in dem die Schraubenwelle eingeschraubt ist, als einstückiger Harzabschnitt ausgebildet sind.



DE 100 30 140 A 1

Beschreibung

Die vorliegende Erfindung betrifft eine Gleitschienen- oder Gleitführungseinheit zur Verwendung in einer Halbleiterprüfvorrichtung oder einer ähnlichen Vorrichtung, die einen auf einem Gleitelement angeordneten beweglichen Körper, z. B. einen Tisch, entlang einer Laufschiene linear führt, und insbesondere eine Gleitschienen- oder Gleitführungseinheit mit einer in das Gleitelement geschraubten und sich durch das Gleitelement hindurch erstreckenden Schraubenwelle zum linearen Antreiben des Gleitelements.

In der JP-A-273550/1997 ist eine derartige Gleitführungseinheit beschrieben. Die Gleitführungseinheit weist auf: eine Laufschiene, die in der Form eines Kanals mit einer konkaven Nut ausgebildet ist und eine entlang ihrer Länge ausgebildete Gleitführungsfläche aufweist, eine in der konkaven Nut entlang der Länge der Laufschiene angeordnete Schraubenwelle und ein Gleitelement mit einem Gleitkontaktelement, das dafür vorgesehen ist, mit der Gleitführungsfläche der Laufschiene in Kontakt zu stehen, und einem Mutterelement, das dafür vorgesehen ist, auf die Schraubenwelle geschraubt zu werden, wobei, wenn die Schraubenwelle beispielsweise durch einen Motor gedreht wird, das Gleitelement sich gemäß dem Umdrehungsmaß in der konkaven Nut der Laufschiene bewegt, so daß das Maß der geradlinigen Bewegung des auf dem Gleitelement angeordneten, zu führenden beweglichen Körpers, z. B. eines Tischs, in jede Richtung durch das Umdrehungsmaß der Schraube präzise bestimmt ist.

Das Gleitelement wird durch einen Gleitkontakt zwischen seinem Gleitkontaktelement und der Gleitführungsfläche der Laufschiene beweglich gehalten. Das Gleitkontaktelement besteht aus einem abriebfesten Material, z. B. aus einem kohlenstoffaserhaltigen Harz, Keramik oder einer Sinterlegierung. In der JP-A-273550/1997 wird vorgeschlagen, daß das Gleitkontaktelement an einer Position mit dem Gleitelement verbunden ist, die der Gleitführungsfläche auf der Laufschiene zugewandt ist, und wenn ein Harzmaterial, z. B. Harz mit darin dispergierten Kohlenstoffasern oder Harz mit darin dispergiertem Metallpulver, zum Herstellen des Gleitkontaktelements verwendet wird, kann es durch Spritzgießen auf dem Gleitelement ausgebildet werden.

Andererseits weist der Mutterabschnitt zum Umwandeln der Drehbewegung der Schraubenwelle in die lineare Bewegung des Gleitelements ein Innengewinde auf, das dazu vorgesehen ist, mit dem auf der Schraubenwelle ausgebildeten Außengewinde in Gleitkontakt zu stehen, und der Mutterabschnitt besteht aus einem abriebfesten und belastungswiderstandsfähigen Material. Das Mutterelement wird mit dem auf dem Gleitelement ausgebildeten Durchgangsloch verbunden.

Bei der Gleitführungseinheit mit einer solchen Struktur müssen, weil von dem auf die Schraubenwelle aufgeschraubten Mutterabschnitt eine Antriebskraft entlang der Laufschiene auf das Gleitelement ausgeübt wird und das Gleitelement durch den Gleitkontakt mit der Gleitkontaktfläche der Laufschiene frei hin- und herbeweglich gehalten wird, das Mutterelement und das Gleitkontaktelement am Gleitelement stabil bzw. sicher befestigt sein, so daß sie sich nicht vom Gleitelement lösen können.

Bei der in der JP-A-273550/1997 beschriebenen Gleitführungseinheit besteht jedoch, weil das Mutterelement und das Gleitkontaktelement nur durch einen Klebstoff am Gleitelement befestigt sind, der Nachteil, daß das Mutterelement oder das Gleitkontaktelement sich aufgrund einer in Bewegungsrichtung des Gleitelements auf das Mutterelement oder das Gleitkontaktelement ausgeübten großen Kraft zufällig vom Gleitelement lösen kann, wenn die Bewegungsrichtung des Gleitelements plötzlich umgekehrt wird.

Um das Mutterelement und das Gleitkontaktelement so am Gleitelement zu befestigen, daß sie einer solchen Kraft widerstehen, kann ein Paar Abdeckkörper beispielsweise durch Bolzen an der vorderen und der hinteren Stirn- oder Endfläche des Gleitelements befestigt werden, so daß die Abdeckkörper das Mutterlement und das Gleitkontaktelement auf dem Gleitelement halten. Durch Bereitstellen solcher Abdeckkörper auf dem Gleitelement erhöhen sich jedoch der Zeit- und Arbeitsaufwand zum Zusammensetzen oder Montieren des Gleitelements und nimmt die Anzahl der Komponenten zu, wodurch höhere Kosten entstehen. Außerdem nimmt, wenn die Abdeckkörper an der vorderen und der hinteren Endfläche des Gleitelements befestigt sind, wie vorstehend beschrieben, die Länge des Gleitelements um die der Länge dieser Abdeckkörpern entsprechende Länge zu, wodurch die Größe der Einheit selbst bezüglich des Hubwegs der hin- und hergehenden Bewegung des Gleitelements zunimmt.

Es ist Aufgabe der Erfindung, die vorstehend beschriebenen Probleme zu lösen und eine Gleitführungseinheit bereitzustellen, bei der das Mutterelement zum Ausüben einer Antriebskraft auf das Gleitelement und das Gleitkontaktelement, durch das das Gleitelement bezüglich der Laufschiene in Bewegung gehalten wird, stabil bzw. sicher am Gleitelement befestigt sind und das auf einfache Weise, kostengünstig und ohne Erhöhung der Anzahl von Komponenten herstellbar ist.

Um die vorstehend beschriebene Aufgabe zu lösen, weist die erfindungsgemäße Gleitführungseinheit auf: eine Laufschiene mit einer entlang ihrer Länge ausgebildeten Gleitführungsfläche, eine parallel zur Laufschiene angeordnete Schraubenwelle mit einer auf ihrem Außenumfang ausgebildeten schraubenförmigen Führungs- oder Gleitgewinderille bzw. -nut und ein Gleitelement mit einem Gleitkontaktelement, das dafür vorgesehen ist, mit der Gleitführungsfläche der Laufschiene in Kontakt gebracht zu werden, und einem Mutterabschnitt, der dafür vorgesehen ist, auf die Schraubenwelle aufgeschraubt zu werden, um den beweglichen Körper gemäß der Drehbewegung der Schraubenwelle entlang der Laufschiene zu führen, wobei das Gleitelement aufweist: einen Metallkernblock mit einer Oberfläche, auf der der bewegliche Körper angeordnet werden kann, und einen durch Gießen um den Metallkernblock herum ausgebildeten Harzabschnitt, und wobei der Gleitkontaktabschnitt und der Mutterabschnitt in diesem einstückigen Harzabschnitt ausgebildet sind.

Gemäß der vorstehend beschriebenen Struktur sind, weil das Gleitelement durch Gießen eines Harzabschnitts um den Metallkernblock herum gebildet wird, und weil das mit der Laufschiene in Kontakt stehende Gleitkontaktelement und das auf die Schraubenwelle geschraubte Mutterelement in diesem einstückigen Harzabschnitt ausgebildet sind, der Mutterabschnitt und der Gleitkontaktabschnitt relativ zueinander fest integriert, wodurch verhindert wird, daß der Mutterabschnitt und der Gleitkontaktabschnitt sich vom Gleitelement lösen, auch wenn die Bewegungsrichtung des Gleitelements plötzlich umgekehrt wird. Außerdem können, weil das Gleitkontaktelement und das Mutterelement durch Spritzgießen auf dem in einer Metallform eingesetzten Kernblock gleichzeitig hergestellt werden können, die Anzahl von Arbeitsvorgängen und die Anzahl von Komponenten, die zum Herstellen des Gleitelements erforderlich sind, reduziert werden, so daß das Gleitelement kostengünstig herstellbar ist.

Aus dem Gesichtspunkt des stabileren Integrierens des Harzabschnitts und des Gleitkontaktabschnitts relativ zueinander ist es bevorzugt, den Harzabschnitt so auf dem Kernblock so auszubilden, daß er die vordere, die hintere, die rechte und die linke Seite des Gleitelements umschließt. Bei einer solchen Struktur kann der Kernblock in der Bewegungsrichtung des Gleitelements nicht vom Harzabschnitt getrennt werden, so daß das Gleitkontaktelement und der Mutterabschnitt, die im Harzabschnitt ausgebildet werden, einstückig in das Gleitelement integrierbar sind.

Aus dem Gesichtspunkt des Eliminierens des Ratterns des Gleitelements bezüglich der Laufschiene und des Gang- oder Bewegungsfehlers während der hin- und hergehenden Bewegung ist es vorteilhaft, das Gleitelement so zu konstruieren, daß das Gleitkontaktelement und/oder der Mutterabschnitt des Gleitelements mit der Gleitführungsfläche der Laufschiene und der Gleitgewinderille der Schraubenwelle elastisch in Kontakt kommen. Beispielsweise kann dem Gleitkontaktelement und/oder dem Mutterabschnitt Elastizität verliehen werden, indem im Gleitkontaktelement und/oder im Mutterabschnitt entlang der Länge des Gleitelements ein Schlitz ausgebildet wird.

Wie vorstehend beschrieben wurde, sind erfindungsgemäß, weil der mit der Laufschiene in Kontakt stehende Gleitkontaktabschnitt und der auf die Schraubenwelle aufzuschraubende Mutterabschnitt durch Gießen eines Harzes um den Metallblock herum ausgebildet sind und das Gleitkontaktelement und der Mutterabschnitt einstückig ausgebildet sind, der Mutterabschnitt und der Gleitkontaktabschnitt fest mit dem Gleitelement integriert, so daß das Mutterelement zum Ausüben einer Antriebskraft auf das Gleitelement und das Gleitkontaktelement, durch das das Gleitelement bezüglich der Laufschiene in Bewegung gehalten wird, stabil am Gleitelement befestigt werden können.

Außerdem wird, weil das Gleitkontaktelement und der Mutterabschnitt durch Spritzgießen gleichzeitig auf dem Gleitelement ausgebildet werden, während der Kernblock in der Metallform eingesetzt ist, die Anzahl von Arbeitsvorgängen und die Anzahl von Komponenten, die zum Herstellen des Gleitelements erforderlich ist, vermindert, so daß das Gleitelement auf einfache Weise und kostengünstig herstellbar ist.

Nachstehend wird die erfindungsgemäße Gleitführungseinheit unter Bezug auf die beigefügten Zeichnungen ausführlich beschrieben.

Fig. 1 und 2 zeigen die erste Ausführungsform einer erfindungsgemäßen Gleitführungseinheit. Bezugszeichen **1** bezeichnet eine Laufschiene in Form eines Kanals mit einer konkaven Nut, 2 eine in der konkaven Nut parallel zur Laufschiene **1** angeordnete Schraubenwelle und 3 ein auf die Schraubenwelle **2** aufzuschraubendes Gleitelement, das in der konkaven Nut der Laufschiene **1** hin- und hergehend beweglich ist.

Die Laufschiene **1** ist definiert durch einen unteren Abschnitt **11** und ein Paar Seitenwände **11** und **12**, die sich von beiden Rändern des unteren Abschnitts **11** vertikal nach oben erstrecken, um einen D-förmigen Querschnitt zu bilden, und Bolzeneinführöffnungen **13** sind in vorgegebenen Abständen auf dem unteren Abschnitt **11** in Längsrichtung ausgebildet, um die Laufschiene **1** auf einem festen Abschnitt, z. B. einem Bett, zu befestigen. Die Innenfläche jeder Seitenwand **12** weist eine entlang ihrer Länge annähernd V-förmig ausgebildete Führungsnut **14** auf, und jede Führungsnut wird durch ein Paar Gleitführungsflächen **14**a und **14**b gebildet, die bezüglich der beide Flächen schneidenden horizontalen Linie um 45° geneigt sind.

Die Schraubenwelle **2** ist in der konkaven Nut angeordnet, die durch ein Paar Seitenwände **12** auf der Laufschiene **1** gebildet wird, und wird durch eine an einem Ende der Laufschiene **1** befestigte Halteplatte und durch das Gleitelement **3** drehbar gehalten. Auf dem Außenumfang der Schraubenwelle **2** ist eine schraubenförmige Gleitgewinderille **21** ausgebildet, so daß, wenn die Schraubenwelle **2** durch den nicht dargestellten Motor gedreht wird, der über die Halteplatte **15** an der Laufschiene **1** befestigt ist, das darauf geschraubte Gleitelement **3** sich gemäß der Drehbewegung der Schraubenwelle **2** in der konkaven Nut auf der Laufschiene bewegt.

Andererseits ist das Gleitelement **3** näherungsweise rechteckig ausgebildet und mit einem gewissen Spiel ebenfalls in die konkave Nut auf der Führungsschiene **1** eingepaßt. Der obere Abschnitt des Gleitelements **3** weist eine Montagefläche **30** zum Befestigen des beweglichen Körpers (nicht dargestellt), z. B. eines Tischs, auf, und die Montagefläche **10** weist Gewindelöcher **34** zum Befstigen des beweglichen Körpers durch Schraubenbolzen auf. Auf beiden Seitenflächen des Gleitelements **3**, d. h. auf der linken und der rechten Seite bezüglich seiner Bewegungsrichtung, sind Gleitkontaktelemente **31** angeordnet, die näherungsweise V-förmig ausgebildet sind, um sie jeweils in die auf der Laufschiene **1** ausgebildeten Führungsnuten **14** enganliegend einzupassen, und die schräg nach oben verlaufende Fläche und die schräg nach unten verlaufende Fläche des Gleitkontaktelements **31** werden mit den Gleitführungsflächen **14**a, **14**b der Führungsnut **14** in Kontakt gehalten. Dadurch bilden die Führungsnut **14** und das Gleitkontaktelement **31** einen Gleitführungsmechanismus, wobei das Gleitelement **3** sich durch Ausüben einer Kraft auf das Gleitelement **3** von irgendeiner Richtung parallel zur Ebene von **Fig.** 2 in der konkaven Nut auf der Laufschiene **1** hin- und hergehend bewegen kann.

Das Gleitelement **3** weist einen auf die Schraubenwelle **2** aufzuschraubenden Mutterabschnitt **32** auf. Wie in **Fig.** 3 dargestellt, weist der Mutterabschnitt **32** ein Durchgangsloch **33** zum Aufnehmen der Schraubenwelle **2** auf, und die Innenumfangsfläche des Durchgangslochs **33** weist ein Innengewinde auf, das dazu vorgesehen ist, mit der auf der Schraubenwelle **2** als Außengewinde ausgebildeten Gleitgewinderille **11** in Eingriff zu kommen.

Wie in den **Fig.** 3 und 4 dargestellt, weist das Gleitelement **4** einen Metallkernblock **4** mit einer Montagefläche **30** für einen beweglichen Körper und einen durch Spritzgießen um den Kernblock **4** herum ausgebildeten Harzabschnitt **5** auf. Weil die Montagefläche **30** hochgradig präzise starr sein muß, um den beweglichen Körper präzise zu befestigen bzw. zu fixieren, und die Gewindelöcher **34** mechanisch fest bzw. stabil sein müssen, sind sie auf dem Metallblock **4** ausgebildet. Weil andererseits der Gleitkontaktabschnitt **31** und der Mutterabschnitt **32** in Gleitkontakt mit den Gleitführungsflächen **14**a, **14**b der Laufschiene **1** und der auf der Schraubenwelle **2** ausgebildeten Gleitgewinderille gehalten werden, müssen sie abriebfest sein und einen kleinen Reibungskoeffizienten aufweisen, so daß sie aus dem Harzabschnitt **5** gebildet sind. Als Material für den Harzabschnitt **5** kann ein Harz verwendet werden, das darin in einem vorgegebenen Verhältnis dispergierte Kohlenstoffasern oder Metallpulver enthält, um die mechanische Festigkeit zu verbessern. Außerdem kann beispielsweise ein Oleoresin oder Ölharz verwendet werden, um eine Schmierung der Gleitführungsflächen **14**a, **14**b und der Gleitgewinderille zu ermöglichen.

Wie in **Fig.** 4 dargestellt, weist der Kernblock **4** einen die Montagefläche **30** definierenden horizontalen Abschnitt **40** und ein Paar Randabschnitte **41, 41** auf, die sich von beiden Enden des horizontalen Abschnitts **40** nach unten erstrekken, und der den Mutterabschnitt **32** bildende Harzabschnitt **5** ist in der Vertiefung **42** ausgebildet, die vom horizontalen Abschnitt **40** und den Randabschnitten **41, 41** umgeben ist. Außerdem ist eine Vertiefung **43** auf der Außenseite jedes Randabschnitts **41** entlang der Bewegungsrichtung des Gleitelements **3** ausgebildet, und in der Vertiefung **43** ist der das Gleitkontaktelement **31** bildende Harzabschnitt **5** ausgebildet. Bei dieser Ausführungform werden das Gleitkontaktelement und der Mutterabschnitt so ausgebildet, daß die Wellenmitte der Schraubenwelle **2** und die Mitte des näherungsweise V-förmigen Gleitkontaktelements **31** auf der gleichen Höhe horizontal zueinander angeordnet sind.

Obwohl der Mutterabschnitt **32** und der Gleitkontaktabschnitt **31** jeweils in Vertiefungen **42, 43** des Kernblocks eingepaßt sind, könnten sie beispielsweise bei einer plötzlichen Umkehr der Bewegungsrichtung des Gleitelements **3** auch vom Kernblock **4** gelöst werden, wenn am vorderen und am hinteren Ende des Gleitelements **3** keine Elemente vorgesehen sind, um sie zu halten. Daher ist, wie in **Fig.** 2 dargestellt, das Gleitelement **3** bei dieser Ausführungsform so konstruiert, daß sowohl auf der vorderen als auch auf der hinteren Endfläche des Kernblocks **4** plattenförmige Verbindungsabschnitte **35** durch Harz gebildet sind, so daß das Gleitkontaktelement **31** und der Mutterabschnitt **32** über einen Verbindungsabschnitt **35** einen einstückigen Harzabschnitt **5** bilden.

Daher sind bei dieser Ausführungsform das Gleitelement **3**, der Mutterabschnitt **32** und das Gleitkontaktelement **31**, die durch Gießen eines Harzes gebildet werden, so integriert, daß sie den Randabschnitt **41** des Kernblocks umgeben, und der Harzabschnitt **5** ist auf dem Kernblock so ausgebildet, daß er die vordere, die hintere, die linke und die rechte Seite des Gleitelements umschließt. Dadurch sind der Kernblock **4** und das Gleitkontaktelement **31** und der Mutterabschnitt **43**, die durch Gießen eines Harzes gebildet werden, fest integriert, und dadurch wird eine Trennung des Mutterabschnitts **32** und des Gleitkontaktabschnitts **31** vom Gleitelement **3** auch dann zuverlässig verhindert, wenn eine hohe Kraft auf das Gleitelement **3** ausgeübt wird, wenn z. B. die Bewegungsrichtung der Schraubenwelle **2** plötzlich umgekehrt wird.

Außerdem können das Gleitkontaktelement **31** und der Mutterabschnitt **32** gleichzeitig gegossen werden, indem der Spritzgießvorgang des Harzabschnitts **5** ausgeführt wird, während der Kernblock **4** in der Metallform eingesetzt ist, und die Trennung oder Ablösung des Harzabschnitts **5** und des Kernblocks **4** kann verhindert werden, indem das Gleitkontaktelement **31** und der Mutterabschnitt **32** einstückig ausgebildet werden. Dadurch kann die Anzahl von Arbeitsvorgängen und der Komponenten im Vergleich mit dem Fall, wenn das Gleitkontaktelement **31** und der Mutterabschnitt **32** einzeln mit dem Gleitelement **3** verbunden werden, vermindert werden, so daß die Gleitführungseinheit wesentlich kostengünstiger herstellbar ist.

Außerdem kann die Halteplatte **15** bei dieser Ausführungsform der Gleitführungseinheit durch Spritzgießen eines Harzes an einem Ende der Laufschiene **1** fixiert ausgebildet werden. D. h., die Halteplatte **15** kann an einem Ende der Laufschiene **1** gegossen und fixiert werden, indem ein Ende der Laufschiene **1** in die Metallform eingesetzt und dort fixiert wird und anschließend ein Harz in die Metallform eingespritzt wird. Bei dieser Struktur muß die Halteplatte **15** nicht nachträglich an der Laufschiene **1** fixiert werden, so daß der zum Ausrichten der Wellenmitte der Schraubenwelle **2**, die durch die Halteplatte **15** bezüglich der Laufschiene drehbar gehalten wird, erforderliche Zeit- und Arbeitsaufwand reduziert wird.

Fig. 5 und 6 zeigen die zweite Ausführungsform einer erfindungsgemäßen Gleitführungseinheit.

Während die Vertiefung **42** des Kernblocks **4**, wo der Mutterabschnitt ausgebildet ist, bei der ersten Ausführungsform auf der Unterseite des Kernblocks **4** angeordnet ist, ist die Vertiefung **44** in der zweiten Ausführungsform in der Mitte auf der Oberseite des Kernblocks ausgebildet, und der Mutterabschnitt **32** ist durch Spritzgießen innerhalb der Vertiefung **44** ausgebildet. Daher stimmen in der zweiten Ausführungsform die horizontale Höhe der Wellenmitte der Schraubenwelle **2** und der Mitte des Gleitkontaktelements **31** anders als bei der ersten Ausführungsform nicht miteinander überein. Andere Merkmale, z. B., daß die vordere und die hintere Endfläche des Kernblocks **4** mit dem aus Harz hergestellten Verbindungsabschnitt bedeckt sind, und daß der Gleitkontaktabschnitt **31** und der Mutterabschnitt **32** als einstückiger Harzabschnitt **5** ausgebildet sind, sind die gleichen wie bei der ersten Ausführungsform. Daher werden die in Verbindung mit der ersten Ausführungsform verwendeten Bezugszeichen auch in den **Fig.** 5 und 6 verwendet, und eine detaillierte Beschreibung wird weggelassen.

Fig. 7 und 8 zeigen eine dritte Ausführungsform einer erfindungsgemäßen Gleitführungseinheit.

Wenn zwischen den Gleitführungsflächen **14**a, **14**b und dem Gleitkontaktelement **31** des Gleitelements **3** und zwischen der Gleitgewinderille **21** der Schraubenwelle **2** und dem darauf aufzuschraubenden Mutterabschnitt **32** Spiel vorhanden ist, können durch die durch die Drehbewegung der Schraubenwelle **2** verursachte hin- und hergehende Bewegung des Gleitelements **3** Rattern des Gleitelements **3** oder wiederholte Fehlausrichtungen verursacht werden, so daß der am Gleitelement **3** befestigte bewegliche Körper, z. B. ein Tisch, nicht präzise geführt werden kann.

Daher ist in der dritten Ausführungsform in der Mitte des näherungsweise V-förmigen Gleitkontaktelements **31** entlang seiner Länge ein Schlitz **36** ausgebildet, so daß das Gleitkontaktelement **31** sich zu jeder der Gleitführungsflächen **14**a, **14**b hin elastisch öffnet, um das Spiel zwischen dem Gleitkontaktelement **31** und den Gleitführungsflächen **14**a, **14**b zu eliminieren. D. h., das Gleitkontaktelement **31** auf der Seite des Gleitelements **3** ist etwas größer ausgebildet als die V-förmige Führungsnut **14** auf der Seite der Laufschiene **1**, und das Gleitelement **3** wird in die Laufschiene **1** eingesetzt, indem das Gleitkontaktelement **31** zusammengedrückt wird, um die Breite des Schlitzes **36** zu vermindern.

Dadurch wird das Gleitkontaktelement **31** mit den jeweiligen Gleitführungsflächen **14**a, **14**b elastisch in Kontakt gebracht, wodurch das Spiel dazwischen eliminiert und das Rattern des Gleitelements **3** verhindert werden kann.

Andererseits ist, um das Spiel zwischen der auf der Schraubenwelle **2** ausgebildeten Gleitgewinderille **21** und dem Mutterabschnitt **32** zu eliminieren, auf dem Mutterabschnitt **32** entlang der Länge des Gleitelements **3** ein Schlitz **37** ausgebildet, so daß der Mutterabschnitt **32** die Schraubenwelle **2** elastisch zusammendrückt. Um die Flexibilität des Mutterabschnitts **32** zu vergrößern, wird der Mutterabschnitt **32** nicht so gegossen, daß er die Vertiefung **42** des Kernblocks **4** füllt, wie in der ersten Ausführungsform, sondern so ausgebildet, daß er die Schraubenwelle **2** ringförmig umschließt. D. h., der Mutterabschnitt **32** wird so gegossen, daß der Innendurchmesser des Mutterabschnitts **32** etwas kleiner ist als der Außendurchmesser der Schraubenwelle **2**, so daß, wenn die Schraubenwelle **2** in den Mutterabschnitt **32** geschraubt wird, veranlaßt wird, daß der Schlitz **37** sich öffnet. Dadurch kommt der Mutterabschnitt **32** mit der auf der Schraubenwelle **2** ausgebildeten Gleitgewinderille elastisch in Kontakt, so daß das Spiel dazwischen eliminiert wird und die Präzision der wiederholten Ausrichtungen während einer hin- und hergehenden Bewegung des Gleitelements **3** verbessert werden kann. Weil die von dem vorstehend dargestellten Punkt verschiedene Struktur die gleiche ist wie bei der ersten Ausführungsform, werden in den Figuren die gleichen Bezugszeichen verwendet, und eine ausführliche Beschreibung wird weggelassen.

Die **Fig.** 9 und 10 zeigen die vierte Ausführungsform eines erfindungsgemäßen Gleitführungselements.

Bei der in **Fig.** 1 dargestellten ersten Ausführungsform einer Gleitführungseinheit ist die Laufschiene **1** in Form eines Kanals ausgebildet, und das Gleitelement **3** ist so konstruiert, daß es sich durch die Drehbewegung der Schraubenwelle **2** in der konkaven Nut der Laufschiene **1** hin- und hergehend bewegt, die Laufschiene **6** der vierten Ausführungsform ist jedoch so ausgebildet, daß sie einen näherungsweise rechteckigen Querschnitt hat, und das Gleitelement **7** ist quer über die Laufschiene **6** angeordnet. Außerdem wird die Schraubenwelle **8** durch die auf der Laufschiene befestigte Halteplatte **62** drehbar gehalten und ist in das Gleitelement **7** geschraubt.

Auf beiden Seiten der Laufschiene **6**, die einen rechteckigen Querschnitt hat, sind näherungsweise V-förmige Führungsnuten **61** ausgebildet, so daß die nach unten geneigte Fläche und die nach oben geneigte Fläche, die die Führungsnut **61** definieren, als Gleitführungsflächen **61**a, **61**b zum Führen des Gleitelements **7** dienen.

Andererseits wird, wie in den **Fig.** 11 und 12 dargestellt, das Gleitelement **7** durch Ausbilden eines Harzabschnitts **10** durch Spritzgießen auf dem Metallkernblock **9** ausgebildet. Das zum Spritzgießen verwendete Harz kann das gleiche sein wie das in der ersten Ausführungsform dargestellte Harz. Der Kernblock **9** hat einen H-förmigen Querschnitt mit konkaven Nuten auf seinem oberen Abschnitt und auf seinem unteren Abschnitt entlang der Länge des Gleitelements. In der unteren konkaven Nut **90** ist die Laufschiene **6** mit einem geringen Spiel lose eingepaßt, und in der oberen konkaven Nut **91** ist der Mutterabschnitt, in den die Schraubenwelle **8** eingeschraubt wird, durch ein Harz gegossen. Die obere Fläche des Kernblocks **9** auf der rechten und der linken Seite der oberen konkaven Nut dient als Montagefläche **92** für den beweglichen Körper, z. B. einen Tisch, und auf der Montagefläche **92** sind Gewindelöcher **93** zum Befestigen des beweglichen Körpers ausgebildet.

Auf den Innenflächen eines Paars von Randabschnitten **94**, **94**, die die untere konkave Nut **90** auf dem Kernblock **9** bilden, ist entlang der Länge des Gleitelements **7** eine Vertiefung **95** ausgebildet, und in der Vertiefung **95** ist ein V-förmiges, hervorstehendes Gleitkontaktelement **72** durch ein Harz gegossen. Das Gleitkontaktelement **72** wird in die Führungsnut **61** auf der Laufschiene **6** enganliegend angepaßt und bildet einen Gleitführungsmechanismus zum Halten des Gleitelements **7** in seiner hin- und hergehenden Bewegung zwischen dem Paar Gleitführungsflächen **61**a, **61**b.

Außerdem sind in der vierten Ausführungsform der Gleitführungseinheit, um den aus Harz gegossenen Mutterabschnitt und das Gleitkontaktelement **72** fest am Kernblock **9** zu fixieren, plattenförmige Verbindungsabschnitte **73** auf der vorderen und der hinteren Endfläche des Gleitelements **7** aus Harz so gegossen, daß der Kernblock **9** bedeckt wird, wodurch der Mutterabschnitt **71** und der Gleitkontaktabschnitt **72** einstückig ausgebildet sind. D. h., weil der Mutterabschnitt **71** und das Gleitkontaktelement **72** als ein Teil des Harzabschnitts **10** so integriert sind, daß sie den Kernblock **9** umgeben, sind der Kernblock **9** und das Gleitkontaktelement **72** und der Mutterabschnitt **71**, die aus einem Harz gegossen sind, fest integriert, wodurch sicher verhindert wird, daß der Mutterabschnitt **71** und das Gleitkontaktelement **72** sich vom Gleitelement **7** lösen, auch wenn durch eine plötzliche Änderung der Bewegungsrichtung der Schraubenwelle **8** eine größere Last auf das Gleitelement **7** ausgeübt wird.

Patentansprüche

1. Gleitführungseinheit mit:
einer Laufschiene mit einer Gleitführungsfläche entlang ihrer Länge;
einer Schraubenwelle, die parallel zur Laufschiene angeordnet ist und auf ihrem Außenumfang eine schraubenförmige Gleitgewinderille aufweist; und
einem Gleitelement mit einem Gleitkontaktelement, das dazu vorgesehen ist, mit der Gleitführungsfläche der Laufschiene in Kontakt gebracht zu werden, und einem auf die Schraubenwelle aufzuschraubenden Mutterabschnitt zum Führen eines beweglichen Körpers durch die Drehbewegung der Schraubenwelle entlang der Laufschiene;
dadurch gekennzeichnet, daß das Gleitelement einen Metallkernblock mit einer Montagefläche aufweist, auf der ein beweglicher Körper montierbar ist, und einen um den Kernblock herum durch Gießen ausgebildeten Harzabschnitt, und dadurch, daß das Gleitkontaktelement und der Mutterabschnitt in diesem einstückigen Harzabschnitt ausgebildet sind.
2. Gleitführungseinheit nach Anspruch 1, dadurch gekennzeichnet, daß der Harzabschnitt auf dem Kernblock so ausgebildet ist, daß er die vordere, die hintere, die linke und die rechte Seite des Gleitelements umgibt.
3. Gleitführungseinheit nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß das Gleitkontaktelement und/oder der Mutterabschnitt des Gleitelements so konstruiert sind, daß sie mit der Gleitführungsfläche der Laufschiene oder mit der Gleitgewinderille der Schraubenwelle elastisch in Kontakt gebracht werden können.
4. Gleitführungseinheit nach Anspruch 3, dadurch gekennzeichnet, daß das Gleitkontaktelement und/oder der Mutterabschnitt des Gleitelements einen Schlitz entlang der Länge des Gleitelements aufweisen, wodurch dem Gleitkontaktelement und/oder dem Mutterabschnitt Elastizität verliehen wird.
5. Gleitführungseinheit nach einem der vorangehen-

den Ansprüche, dadurch gekennzeichnet, daß eine Halteplatte aus Harz an einem Ende der Laufschiene in ihrer Breitenrichtung angeordnet ist, um die Schraubenwelle drehbar zu halten, und die Halteplatte durch Gießen auf der Laufschiene ausgebildet ist.

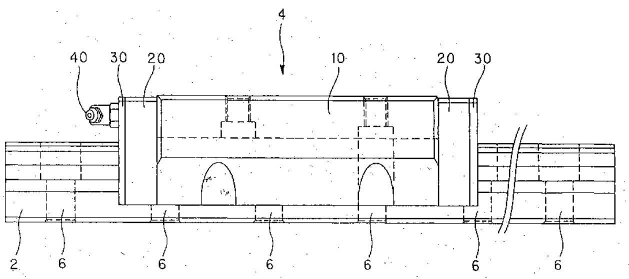
Die folgenden Angaben sind den vom Anmelder eingereichten Unterlagen entnommen

(54) Lineare Bewegungsvorrichtung

(57) Die Erfindung betrifft eine lineare Bewegungsvorrichtung, die eine Führungsschiene (2) mit Laufflächen (5) für Laufrollen (3) und einen auf der Führungsschiene bewegbaren Block (4), Endplatten (20), die an einander gegenüberliegenden Enden des Blocks in seiner Bewegungsrichtung vorgesehen sind und ein Endabdichtelement (30) aufweist, das an der Außenseite an jeder Endplatte vorgesehen ist. Ein Schmiermittel-Speicherelement (28), in dem sich Schmiermittel befindet, ist an jeder Endplatte (20) vorgesehen. Ein Auftragelement (31) zum Auftragen des von dem Schmiermittel-Speicherelement kommenden Schmiermittels auf die Führungsschiene ist an dem Endabdichtelement (30) vorgesehen.



DE 100 26 587 A 1

Beschreibung

Die Erfindung betrifft eine lineare Bewegungsvorrichtung, wie beispielsweise für eine Linearführung, eine Kugelspindel, eine Kugelwellennute oder dergleichen, in der eine Führungsschiene und ein Gleitkörper miteinander über Rollenelemente, wie beispielsweise Kugeln, Walzen oder dergleichen, kombiniert sind, um so eine Relativbewegung ausführen zu können, und insbesondere eine Verbesserung in einer linearen Bewegungsvorrichtung, die mit einer Schmiermittel-Zuführvorrichtung zum Aufbringen eines Schmiermittels auf die Oberfläche der Führungsschiene versehen ist.

Hinsichtlich einer Vorrichtung zum präzisen und reibungslosen Führen eines Tisches eines Maschinenwerkzeugs ist eine lineare Bewegungsvorrichtung bekannt, bei der ein Block durch eine Mehrzahl an Rollenelementen (z. B. Kugeln) auf einer Führungsschiene angeordnet ist (siehe z. B. Vorveröffentlichung des japanischen Patents Nr. H8-305,861).

In einer derartigen linearen Bewegungsvorrichtung ist der Block durch die Rollenelemente (z. B. Kugeln) bewegbar auf der Führungsschiene angeordnet, die Laufflächen für die Rollenelemente aufweist. An den gegenüberliegenden Enden des Blocks sind in Bewegungsrichtung Endplatten vorgesehen. Eine Schmiermittel-Zuführvorrichtung ist an der anderen Seite einer jeden Endplatte vorgesehen.

Die Schmiermittel-Zuführvorrichtung ist mit einem Schmiermittel-Speicherelement zum Aufnehmen eines auf die Führungsschiene aufzutragenden Schmiermittels versehen, einem Auftragelement zum Auftragen des Schmiermittels aus dem Schmiermittel-Speicherelement auf die Führungsschiene und einer Schmiermittel-Steuervorrichtung zwischen dem Schmiermittel-Speicherelement und dem Auftragelement, um die Menge des von dem Schmiermittel-Speicherelements an das Auftragelement zu führenden Schmiermittels zu steuern. Das Schmiermittel-Speicherelement, die Schmiermittel-Steuervorrichtung und das Auftragelement sind einstückig miteinander ausgebildet.

Nach dem Stand der Technik ist die Schmiermittel-Zuführvorrichtung mit einer Behälterform separat an der Außenfläche des Blocks der linearen Bewegungsvorrichtung angeordnet und dort befestigt. Wenn die Bewegungslänge für den Block in der linearen Bewegungsvorrichtung nicht ausreicht, kann keine Schmiermittel-Zuführvorrichtung an den Block hinzugefügt werden oder nur eine Schmiermittel-Zuführvorrichtung kann auf den einander gegenüberliegenden Seiten des Blocks vorgesehen werden, wodurch dann im Gegensatz zum Normalzustand, in dem ein Paar Schmiermittel-Zuführvorrichtungen jeweils auf den gegenüberliegenden Seiten des Blocks vorgesehen sind, Probleme auftauchen. Die Schmiermittel-Zuführvorrichtung ist mit dem Auftragelement für das Schmiermittel einstückig gebildet. Demzufolge ist es in dem Fall, wenn das Auftragelement verschlissen ist und durch ein neues ersetzt werden muss, notwendig, das Auftragelement zusammen mit dem Schmiermittel-Speicherelement auszuwechseln, selbst wenn in dem Schmiermittel-Speicherelement noch Schmiermittel vorhanden ist.

Eine Aufgabe der Erfindung ist es somit, eine lineare Bewegungsvorrichtung zu schaffen, die es ermöglicht, das Schmiermittel-Speicherelement und das Auftragelement für das Schmiermittel separat auswechseln zu können und das Schmiermittel auffüllen zu können und die Vorrichtung in einer kleinen Größe vorzusehen.

Zur Lösung dieser Aufgabe weist eine lineare Bewegungsvorrichtung der Erfindung auf:
eine Führungsschiene mit Laufflächen für Rollenelemente;
einen auf dieser Schiene bewegbaren Block;
Endplatten, die an einander gegenüberliegenden Enden des Blocks in seiner Bewegungsrichtung vorgesehen sind; und
ein Endabdichtelement, das auf einer Außenseite von jeder der Endplatten vorgesehen ist, wobei ein Schmiermittel-Speicherelement zum Aufbewahren eines Schmiermittels an jeder der Endplatten, und ein Auftragelement zum Auftragen des von dem Schmiermittel-Speicherelement geführten Schmiermittels auf die Führungsschiene an dem Endabdichtelement vorgesehen sind.

Gemäß dem oben erwähnten Aufbau der Erfindung ist es möglich, das Schmiermittel-Speicherelement und das Auftragelement separat auszuwechseln. Die Einarbeitung des Schmiermittel-Speicherelements in die Endplatten ermöglicht es, die lineare Bewegungsvorrichtung in geringer Größe vorzusehen.

Die Zuführleitung zum Zuführen des Schmiermittels an das Schmiermittel-Speicherelement kann auf jeder der Endplatten vorgesehen sein. Gemäß einem derartigen Aufbau ist es möglich, das Schmiermittel leicht aufzufüllen, ohne die Endplatte abzunehmen, wenn das in dem Schmiermittel-Speicherelement aufbewahrte Schmiermittel zur Neige geht.

Das Schmiermittel-Speicherelement und das Auftragelement können aus einem Fasermaterial hergestellt sein. Das Fasermaterial des Auftragelements hat vorzugsweise eine größere Dichte als das Fasermaterial des Schmiermittel-Speicherelements.

Eine Vorrichtung zum Justieren der Menge des von dem Schmiermittel-Speicherelement abgeführten Schmiermittels an das Auftragelement kann zwischen dem Schmiermittel-Speicherelement und dem Auftragelement vorgesehen sein.

Die Erfindung wird nun in Bezug auf die beigefügte Zeichnung näher beschrieben. In dieser zeigen:

Fig. 1 eine Seitenansicht einer erfindungsgemäßen linearen Bewegungsvorrichtung;

Fig. 2 einen Querschnitt einer Führungsschiene der erfindungsgemäßen linearen Bewegungsvorrichtung;

Fig. 3 eine Frontansicht eines Blocks der erfindungsgemäßen linearen Bewegungsvorrichtung, wobei der linke Abschnitt in Bezug auf die Schnittlinie III-III im Querschnitt gezeigt ist;

Fig. 4 eine Frontansicht der erfindungsgemäßen linearen Bewegungsvorrichtung, wobei der linke Abschnitt in Bezug auf die Schnittlinie IV-IV im Querschnitt gezeigt ist;

Fig. 5 eine vergrößerte Ansicht des Abschnitts "V" aus **Fig.** 4;

Fig. 6 eine rückwärtige Ansicht der Endplatte der erfindungsgemäßen linearen Bewegungsvorrichtung;

Fig. 7 einen Querschnitt, der die Endplatte und das Endabdichtelement der erfindungsgemäßen linearen Bewegungsvorrichtung zeigt; und

Fig. 8 eine Frontansicht des Endabdichtelements der linearen Bewegungsvorrichtung der Erfindung, wobei der linke Abschnitt in Bezug auf die Schnittlinie IV-IV im Querschnitt dargestellt ist.

Im Folgenden wird nun eine Ausführungsform einer erfindungsgemäßen linearen Bewegungsvorrichtung mit Bezug auf die beigefügte Zeichnung im Detail beschrieben.

Die **Fig.** 1 bis 8 zeigen die lineare Bewegungsvorrichtung der Erfindung. Die lineare Bewegungsvorrichtung **1** ist mit einer als Führungsschiene dienenden Schiene **2** und einem als Block dienenden Gleitkörper **4** versehen, der durch eine Mehrzahl an Rollen (Rollenelemente) **3** auf der Schiene **2** befestigt ist, um so in der Längsrichtung der Schiene **2** bewegbar zu sein. Die Schiene **2** ist mit vier Rollenelement-Laufflächen **5** versehen, die sich über die gesamte Länge der Schiene **2** in ihrer Längsrichtung erstrecken, und mit Bolzenlöchern **6**, durch die hindurch Bolzen zum Befestigen der

Schiene **2** eingesetzt sind. Die dargestellte Schiene **2** hat eine geradlinige Form. Ebenso kann eine Schiene mit einer gekrümmten Form verwendet werden. Die Anzahl der Rollenelement-Laufflächen **5** ist nicht auf vier begrenzt (d. h., zwei Laufflächen an der rechten Seite und zwei Laufflächen an der linken Seite). Eine einzelne Rollenelement-Lauffläche **5** kann an jeder Seite der rechten und linken Schiene vorgesehen sein. Die Gesamtzahl der Rollenelement-Laufflächen kann drei oder vier betragen. Die Anzahl kann entsprechend der Verwendung der linearen Bewegungsvorrichtung variieren.

Wie in den **Fig.** 1 und 3 gezeigt, hat der Gleitkörper **4** einen Gleitblock **10**, genauso wie Endplatten **20** und Endabdichtelemente **30**, die an den einander gegenüberliegenden Enden des Gleitblocks **10** vorgesehen sind. Der Gleitblock **10** hat eine ausreichende Festigkeit um eine auf dem Gleitkörper **4** aufliegende Last zu tragen. Der Gleitblock **10** ist normalerweise aus Stahl gefertigt. Ein Kunstharz-Körper kann in Abschnitten des Gleitblocks **10** eingearbeitet sein, an denen die Last nicht direkt aufgebracht wird. Der Gleitblock **10** hat einen vertieften Abschnitt **11**, der an der Unterseite des Gleitblocks angeordnet ist, um die Schiene **2** aufzunehmen. Die Wandflächen des Gleitblocks **10**, die den vertieften Abschnitt **11** definieren, weisen Rollenelement-Gegenlaufflächen **12** auf, die die Gegenfläche entsprechend den Rollenelement-Laufflächen **5** der Schiene **2** darstellen.

Gemäß den **Fig.** 4 und 5 laufen die Rollen **3** zwischen den Rollenelement-Laufflächen **5** und den Rollenelement-Gegenlaufflächen **12**, wenn der Gleitkörper **4** entlang der Schiene **2** bewegt wird. Die Laufrolle **3**, die das Ende der Rollenelement-Gegenlauffläche **12** erreicht, wird an einen Richtungswechsel-Abschnitt **21** (siehe **Fig.** 6) geführt, der an der Innenseite der Endplatte **20** vorgesehen ist, die sich an einer Seite des Gleitblocks **10** befindet. Dann läuft die Laufrolle **3** durch einen Umkehrdurchgang **13** und einen Richtungswechselabschnitt **21**, der an der Innenseite der Endplatte vorgesehen ist, die sich an der anderen Seite des Gleitblocks **10** befindet, wodurch sie das andere Ende der Rollenelement-Gegenlauffläche **12** erreicht. Der Zwischenraum zwischen der Rollenelement-Lauffläche **5** und der Rollenelement-Gegenlauffläche **12** wird normalerweise als "Lastlaufbereich" für die Laufrollen **3** bezeichnet. Die Kombination der Richtungswechselabschnitte **21** der Endplatte **20** mit dem Umkehrdurchgang **13** des Gleitblocks wird als "unbelasteter Laufbereich" bezeichnet. Die Kombination des Lastlaufbereichs mit dem unbelasteten Laufbereich wird als "Endlos-Schleifendurchlauf" bezeichnet. Wie in **Fig.** 6 gezeigt, hat der Richtungswechselabschnitt **21** ein Paar Richtungswechseldurchgänge **21**a und **21**b, die ein zweiarmiges Kreuz im Inneren der Endplatte **20** bilden. Die Richtungswechseldurchgänge **21**a und **21**b, die das Zweiarm-Kreuz bilden, führen zu einer dicken Erhöhung der Endplatte **20**, wodurch es möglich ist, die Speicherkapazität des Schmiermittel-Speicherelements **28** zu erhöhen, die nachfolgend beschrieben wird. Im Ergebnis ist es möglich, die Anzahl der Rückführ-Verfahrensschritte des Schmiermittels zu reduzieren.

Die Endplatte **20** hat ein Paar Flügelabschnitte **20**b, **20**b und einen Trägerabschnitt **20**a, der die Flügelabschnitte **20**b, **20**b miteinander verbindet, wodurch eine gemäß **Fig.** 6 gezeigte U-Gestalt gebildet wird. Der Trägerabschnitt **20**a der Endplatte **20** hat in seinem mittleren Bereich eine Schmiermittelöffnung **22**, in die ein Schmiernippel **40** eingepasst ist. Die Flügelabschnitte **20**b weisen jeweils die oben erwähnten Richtungswechselabschnitte **21** auf. Die Endplatte **20** hat Schmiermittelleitungen **23**, um das in die Schmiernippel **40** eingespritzte Fett in Richtung der Wechselabschnitte **21** zu führen. Die Endplatte **20** hat einen vertieften Abschnitt **24**, der auf der Unterfläche des Trägerabschnitts **20**a ausgebildet ist, um sich so in einer Querrichtung gemäß **Fig.** 7 zu erstrecken. Verbindungslöcher **25** verbinden den unteren Anteil des vertieften Abschnitts **24** mit der Außenseite der Endplatte **20**. Um die Verbindungslöcher **25** sind O-Ringe **26** angeordnet. Wie in **Fig.** 6 gezeigt, ist eine Schmiermittel-Zuführleitung **27**, die die eine Seitenfläche des Trägerabschnitts **20**a mit dem vertieften Abschnitt **24** funktional verbindet, durch die Kombination eines Vertikallochs **27**a, das sich von der Oberfläche des Trägerabschnitts **20**a in der Vertikalrichtung erstreckt, um mit dem vertieften Abschnitt **24** funktional zu kommunizieren, mit einem Horizontalloch **27**b vorgesehen, das sich von der Seitenfläche in der Horizontalrichtung erstreckt, um mit dem Vertikalloch **27**a funktional zu kommunizieren. Die gleiche Schmiermittel-Zuführleitung **27** ist ebenso an der anderen Seite gemäß **Fig.** 6 vorgesehen. Verschlußstöpsel **27**c verschliessen die oberen Öffnungen der Vertikallöcher **27**a. Die Einlassabschnitte der Schmiermittel-Zuführleitungen **27** sind mit Gewindebohrlochabschnitten **27**d versehen. Die Verschlußstöpsel **27**e stehen mit den Gewindebohrlochabschnitten **27**d im Eingriff, um die Einlassabschnitte zu schließen. Die Verschlußstöpsel **27**e, **27**e können von den Gewindebohrlochabschnitten **27**d abgenommen werden, wenn Schmiermittel aufgefüllt wird. Das Schmiermittel-Speicherelement **28**, das aus einem Fasermaterial, wie beispielsweise einem Fasernetz, hergestellt ist und eine große Menge an Schmiermittel aufnehmen kann, ist in dem vertieften Abschnitt **24** aufgenommen. Ein Teil des Schmiermittel-Speicherelements **28** wird von jedem der Verbindungslöcher **25** aufgenommen, um so von der Endplatte **20** nach außen hervorzuragen. Eine Trägerplatte **29** ist durch eine geeignete Befestigungsvorrichtung an dem offenen Ende des vertieften Abschnitts **24** eingepasst, in dem das Schmiermittel-Speicherelement **28** aufgenommen ist.

Gemäß den **Fig.** 7 und 8 weist das Endabdichtelement **30** einen Dichtungskörper **32** zum Aufnehmen eines Auftragelements **31**, durch das das Schmiermittel auf die Schiene **2** aufgebracht wird, und eine Abdeckung **33** auf, die entlang des Auftragelements **31** angeordnet ist. Das Auftragelement **31** ist aus einem Fasermaterial, wie beispielsweise einem Fasernetz hergestellt. Das Fasermaterial des Auftragelements **31** hat vorzugsweise eine höhere Dichte als das Fasermaterial des Schmiermittel-Speicherelements **28**. Der Abdichtkörper **32** hat Löcher **32**a, die auf Abschnitten ausgebildet sind, die den Rollenelement-Laufflächen **5** entsprechen, wenn der Gleitkörper **4** auf der Schiene **2** angeordnet ist. Teile des Auftragelements **31** stehen von dem Abdichtkörper **32** aus den Löchern **32**a nach außen hervor. Die Abdeckung **33** ist auf dem Auftragelement **31** angeordnet und an dem Abdichtkörper **32** durch eine geeignete Befestigungsvorrichtung befestigt. Die Teile des Schmiermittel-Speicherelements **28**, die von der Endplatte **20** durch die Schmiermittel-Zuführlöcher **32**b hervorstehen, die an der Wand des Abdichtkörpers **32** vorgesehen sind, treten mit dem Auftragelement **31** in Kontakt. Das Endabdichtelement **30** hat ein Durchgangsloch **34**, durch das das Schmiermittel **40** an die Schmiernippel-Einpassöffnung **22** angeschlossen werden kann, die auf der Endplatte **20** vorgesehen ist.

Nachfolgend werden nun die Verfahren zum Zusammenbau des Gleitkörpers **4**, zur Montage des Gleitkörpers auf der Schiene **2** und die Verwendung der linearen Bewegungsvorrichtung beschrieben. Die Endplatte **20** wird an das Ende des Gleitblocks **10** gesetzt und das Endabdichtelement **30** wird an die Außenfläche der Endplatte **20** gepasst. Die Laufrollen **3** werden in den Umkehrdurchgang **13** gesetzt, der an dem anderen Ende des Gleitblocks **10** angeordnet ist. Jede der Laufrollen **3** besteht aus einem Rollenkörper **3**a und einer Welle **3**b. Die Laufrolle **3** wird in den Umkehrdurchgang **13** gesetzt, so dass eine Wellenaufnahmerille **13**a, die an dem Umkehrdurchgang **13** angeordnet ist, die Welle **3**b der Laufrolle **3** aufnimmt. Der Richtungswechselabschnitt **21** wechselt die Bewegungsrichtung der Laufrollen **3**, die die Endplatte **20** erreichen, mit dem Ergebnis, dass sich die Laufrollen **3** an die Rollenelement-Umkehrlauffläche **12** bewegen. Der Endlos-Schleifendurchgang ist mit den Laufrollen **3** angefüllt und die Endplatte **20** und das Endabdichtelement **30** sind an dem anderen Ende des Gleitblocks **10** eingepasst.

Der Gleitkörper **4** ist auf der Schiene durch Einsetzen des Endes der Schiene **2** in den vertieften Abschnitt **11** des Gleitkörpers **4** befestigt. In diesem Zustand kommen die aus den Löchern **32**a hervorstehenden Teile des Auftragelements **31** mit den Rollenelement-Laufflächen **5** in Kontakt.

Dann wird das Schmiermittel durch die Schmiermittel-Zuführleitung **27** abgegeben. Das abgegebene Schmiermittel fällt dann durch das Vertikalloch **27**a nach unten und wird von dem Schmiermittel-Speicherelement **28** absorbiert. Das Schmiermittel wird durch die Teile des Schmiermittel-Speicherelements **28** an das Auftragelement **31** geführt, welche Teile mit dem Auftragelement **31** durch die Verbindungslöcher **25** und den Schmiermittel-Zuführlöchern **32**b in Kontakt kommen.

Dann wird Schmierfett von dem Schmiernippel **40** abgegeben, der in der Schmiernippel-Passöffnung **22** eingepasst ist. Das somit abgegebene Schmierfett wird durch die Schmierfettleitungen **23** an die Richtungswechselabschnitte **21** geführt. Das Schmierfett wird durch die Richtungswechselabschnitte **21** an den Endlos-Schleifendurchgang geführt.

Wenn sich der Gleitkörper **4** auf der Schiene **2** bewegt, bewegt sich das durch das Auftragelement **31**, das mit den Rollenelement-Laufflächen **5** in Kontakt gerät, zur Verfügung gestellte Schmiermittel aufgrund der Kapillarkraft an die Rollenelement-Laufflächen **5**. Wenn die Menge des in dem Auftragelement **31** befindlichen Schmiermittels weniger wird, läuft das Schmiermittel aufgrund der Kapillarkraft von dem Schmiermittel-Speicherelement **28** durch die Schmiermittel-Zuführlöcher **32**b an das Auftragelement **31**. Der Gleitkörper **4** bewegt sich durch die zwischen dem Gleitkörper **4** und der Schiene **2** befindlichen Laufrollen **3** auf der Schiene **2**. Das in den Endlos-Schleifendurchgang eingebrachte Schmierfett schafft eine reibungslose Rollenbewegung der Laufrollen **3**.

Nach einer langen Inbetriebnahme der linearen Bewegungsvorrichtung verschleißt das Auftragelement **31** aufgrund der Reibung mit den Rollenelement-Laufflächen **5** und muss somit durch ein Neues ersetzt werden. In diesem Fall ist es möglich ausschließlich das Auftragelement **31** auszuwechseln, da das Schmiermittelspeicherelement **28** und das Auftragelement **31** separat ausgebildet sind. Damit ist es unnötig, das Schmiermittel-Speicherelement **28** und das darin befindliche Schmiermittel wegzuwerfen.

Die Erfindung ist jedoch nicht auf die oben gezeigte Ausführungsform beschränkt. In dieser Ausführungsform ist die Kontaktfläche des Schmiermittel-Speicherelements mit dem Auftragelement (d. h., die Bereiche seiner Endflächen) konstant. Eine Vorrichtung zum Justieren der Kontaktfläche des Schmiermittel-Speicherelements mit dem Auftragelement (d. h., die Bereiche der Endflächen) kann zwischen ihnen vorgesehen sein, wodurch es möglich wird, die Menge des an das Auftragelement geführten Schmiermittels einzustellen. In der oben gezeigten Ausführung umfasst der Richtungswechselabschnitt das Paar der Richtungswechseldurchgänge, die ein zweiarmiges Kreuz an der Innenseite der Endplatte bilden. Das Paar Richtungswechseldurchgänge kann jeweils parallel miteinander vorgesehen sein, ohne ein derartiges zweiarmiges Kreuz zu bilden. Die Erfindung kann auf jeden Typ einer Vorrichtung, wie beispielsweise eine Kugelspindel, eine Kugelwellennute oder dergleichen Vorrichtung angewendet werden, in der ein Gleitelement, das mit einer Schmiermittelzuführvorrichtung versehen ist, entlang einer Führungsschiene bewegt werden kann.

Gemäß der Erfindung kann das Schmiermittel-Speicherelement und das Auftragelement für das Schmiermittel separat ausgewechselt werden und das Schmiermittel aufgefüllt und die Vorrichtung in einer kleinen Größe ausgeführt werden.

Patentansprüche

1. Lineare Bewegungsvorrichtung, aufweisend:
eine Führungsschiene (**2**) mit Laufflächen (**5**) für Laufrollen (**3**) einen auf der Führungsschiene bewegbaren Block (**4**);
Endplatten (**20**), die an einander gegenüberliegenden Enden des Blocks in seiner Bewegungsrichtung vorgesehen sind; und
ein Endabdichtelement (**30**), das an einer Außenseite an jeder der Endplatten vorgesehen ist, wobei:
zum Aufnehmen eines Schmiermittels ein Schmiermittel-Speicherelement (**28**) an jeder Endplatte (**20**) vorgesehen ist und ein Auftragelement (**31**) an dem Endabdichtelement zum Auftragen des von dem Schmiermittel-Speicherelement abgeführten Schmiermittels auf die Führungsschiene vorgesehen ist.
2. Vorrichtung nach Anspruch 1, wobei eine Zuführleitung (**27**) zum Zuführen des Schmiermittels an das Schmiermittel-Speicherelement (**28**) an jeder Endplatte (**20**) vorgesehen ist.
3. Vorrichtung nach Anspruch 1 oder 2, wobei das Schmiermittel-Speicherelement (**28**) und das Auftragelement (**31**) aus einem Fasermaterial hergestellt sind.
4. Vorrichtung nach Anspruch 3, wobei das Fasermaterial des Auftragelements (**31**) eine höhere Dichte als das Fasermaterial des Schmiermittel-Speicherelements (**28**) hat.
5. Vorrichtung nach einem der Ansprüche 1 bis 4, wobei eine Vorrichtung zum Justieren der Menge des von dem Schmiermittel-Speicherelement (**28**) an das Auftragelement (**31**) geführten Schmiermittels zwischen dem Schmiermittel-Speicherelement und dem Auftragelement vorgesehen ist.

(54) Lineargleitlager

(57) Die Erfindung befaßt sich mit einem linearen Bewegungslager, welches eine extrem hohe Steifigkeit gegenüber einem Belastungsmoment und eine stabile Arbeitsweise hat. Es wird von einer Schienenbahn und einem Gleitstück bzw. einem Schlitten gebildet, welche auf der Schienenbahn angeordnet ist, wobei eine große Anzahl von Kugeln zwischengeschaltet sind. Das Gleitstück hat eine kanalähnliche Gestalt mit einem horizontalen Abschnitt und einem Paar von Randabschnitten, die sich von den gegenüberliegenden Seiten des horizontalen Abschnittes weg erstrecken. Jeder Randabschnitt ist an seiner inneren Seite mit einer Kugelwälzfläche versehen, welche nach oben weist und der horizontale Abschnitt ist in der Nähe des Mittelteils seiner inneren Seite mit wenigstens zwei Kugelwälzflächen versehen, welchen nach unten weisen.

DE 42 27 599 A1

Beschreibung

Die Erfindung befaßt sich mit einem Linearbewegungslager der Bauart für eine gleichförmige Belastung in vier Richtungen, welches als eine Gleitfläche, beispielsweise eines Bearbeitungszentrums und eines Tischschlittens einer Werkzeugmaschine eingesetzt wird, und welches auch an einer Stelle zum hin- und hergehenden Tragen eines schweren Gegenstandes bei einer Transport-Vorrichtung eingesetzt wird.

Ein gegebenes Linearbewegungslager ist in den **Fig.** 6 und 7 gezeigt, welches eine hohe Steifigkeit gegenüber einem Belastungsmoment hat und eine stabile Arbeitsleistung erzielen kann. Insbesondere wird das Lager von einer Schienenbahn **60** gebildet, welche eine große Breite hat und die mit einer Bezugsfläche R mittels Befestigungsschrauben in mehreren Reihen zum Tragen eines Belastungsmomentes fest verbunden ist und ferner umfaßt das Lager ein Gleitstück **50**, welches auf der Schienenbahn **60** angeordnet ist, und eine große Anzahl Kugeln **70**, welche zwischen dem Gleitstück **50** und der Schienenbahn **60** derart angeordnet sind, daß das Gleitstück **50** entlang der Schienenbahn **60** gleitbeweglich ist.

Die Schienenbahn **60** ist an jeder Seitenfläche mit zwei Kugelwälzflächen **61** versehen, welche in eine axiale Richtung verlaufen, und sie ist auch mit Befestigungsöffnungen **62** in mehreren Reihen versehen, über welche die Befestigungsschrauben eingesetzt werden können.

Das Gleitstück **50** wird von einem Lagerkörper **51** und einem Paar von endseitigen Kappen **52** gebildet, welche an den gegenüberliegenden Endflächen des Körpers **51** festgelegt sind. Der Lagerkörper **51** hat einen horizontalen Abschnitt **51**a und ein Paar von Randabschnitten **51**b, welche von den gegenüberliegenden Seiten des horizontalen Abschnittes **51**a ausgehen und somit eine kanalähnliche Gestalt haben. Jeder Randabschnitt **51**b ist an seiner inneren Fläche mit zwei Kugelwälzflächen **51**d versehen, welche den Kugelwälzflächen **61** der Schienenbahn **60** gegenüberliegen. Auch ist jeder Randabschnitt mit Kugelaustrittsöffnungen **51**e versehen, welche axial das massive Teil durchsetzen. Der horizontale Abschnitt **51**a des Lagerkörpers ist an jeder Seite und an jedem Mittelteil mit zwei Befestigungsöffnungen **51**f zum Anbringen und Befestigen eines Tisches T mit Hilfe von sechs Schrauben versehen.

Ferner ist die Endkappe mit Kugelrücklaufausnehmungen versehen, welche die Kugelwälzflächen **51**d des Lagerkörpers **51** mit den Kugelaustrittsöffnungen **51**e verbinden. Endlose Bahnen für die Kugeln werden dadurch gebildet, daß die endseitigen Kappen am Lagerkörper fest angebracht werden.

Halter **80**, welche ein Herausfallen der Kugeln **70** verhindern, wenn das Gleitstück **50** der Schienenbahn **60** abgenommen wird, sind an einem Hohlraum **51**c angebracht, welcher an einer inneren Seite des Lagerkörpers **51** ausgebildet ist und in dem jeweiligen Randabschnitt **51**b endet.

Da ein derart ausgebildetes lineares Bewegungslager eine große Steifigkeit gegenüber dem Belastungsmoment hat, kann es als eine Ein-Achs-Konstruktion bei einem Gleitteil eingesetzt werden, bei dem Lagerungen in zwei oder mehr Achsen infolge eines großen Belastungsmomentes bei den üblichen Auslegungen erforderlich sind, und somit läßt sich ein Raum für das Gleitteil im Vergleich zu den üblichen Auslegungsformen verkleinern.

Bei dem vorstehend beschriebenen, üblichen linearen

Bewegungslager jedoch ist der Abstand W zwischen den Kugeln **70**, welche an den gegenüberliegenden Seiten der Schienenbahn **60** liegen, groß, wie dies in **Fig.** 6 gezeigt ist, so daß ein Mittelteil des horizontalen Abschnitts **51**a des Lagerkörpers **51** sich leicht nach unten auslenken kann.

Bei dem linearen Bewegungslager wird daher die Dikke des horizontalen Abschnittes **51**a des Lagerkörpers **51** vergrößert, um die Steifigkeit zu erhöhen, wodurch aber in unzweckmäßiger Weise ein Abstand von der Bezugsfläche R zu einer Befestigungsfläche des Tisches T, d. h. eine Höhe des Lagers, größer wird.

Um Kugelwälzflächen **51**d in zwei Reihen an dem jeweiligen Randabschnitt **51**b des Lagerkörpers **51** auszubilden, muß ein Raum zwischen den beiden Kugelwälzflächen **51**d größer als ein Durchmesser der Kugel sein, und ferner ist ein gewisser Abstand zwischen dem horizontalen Abschnitt **51**a und der jeweiligen Kugelwälzfläche **51**d, welche in dessen Nähe liegt, im Hinblick auf die maschinelle Bearbeitung mittels einer Schleifmaschine erforderlich. Aus diesen Gründen läßt sich die Höhe des so ausgebildeten linearen Bewegungslagers nicht reduzieren.

Wenn die Höhe des Lagers größer wird, nimmt in unvermeidbarer Weise die Steifigkeit gegenüber dem Belastungsmoment ab, und daher läßt sich die Steifigkeit gegenüber dem Belastungsmoment bei dem linearen Bewegungslager gemäß der üblichen und zuvor beschriebenen Bauform nicht in ausreichender Weise erhöhen.

Ferner sind bei einem so ausgebildeten linearen Bewegungslager die Schrauben zum Befestigen des Tisches T derart angeordnet, daß sie mit dem horizontalen Abschnitt **51**a des Lagerkörpers **51** zusammenarbeiten, so daß eine Verformung des horizontalen Abschnitts **51** in Richtung nach unten verhindert wird. Jedoch läßt sich die Zugkraft durch die Schrauben nicht in einem großen Maße vergrößern, so daß man Vorteile bei dieser Konstruktion nicht in ausreichendem Maße erwarten kann.

Die Erfindung wurde zur Überwindung der vorstehend genannten Schwierigkeiten geschaffen und zielt darauf ab, ein lineares Bewegungslager bereitzustellen, welches eine extrem große Steifigkeit gegenüber dem Belastungsmoment hat sowie die Fähigkeit hat, ein stabiles Arbeitsvermögen beizubehalten.

Nach der Erfindung wird hierzu ein lineares Bewegungslager bereitgestellt, welches ein Gleitstück bzw. einen Schlitten mit einer kanalähnlichen Gestalt aufweist, das einen horizontalen Abschnitt und ein Paar von Randabschnitten hat, die von den gegenüberliegenden Seiten des horizontalen Abschnitts ausgehen, wobei eine Kugelwälzfläche nach oben weist, welche an einer inneren Seite des jeweiligen Randabschnittes ausgebildet ist, und wobei wenigstens zwei Kugelwälzflächen, welche nach unten weisen, in der Nähe eines Mittelteils einer inneren Fläche des horizontalen Abschnittes ausgebildet sind; ferner eine Schienenbahn aufweist, auf der das Gleitstück angeordnet ist, wobei die Schienenbahn an ihren gegenüberliegenden Seitenflächen mit Kugelwälzflächen versehen ist, welche nach unten in Richtung auf die oberen Kugelwälzflächen des Gleitstücks weisen und an ihren oberen Flächen mit Kugelwälzflächen versehen sind, welche nach unten in Richtung auf die unteren Kugelwälzflächen des Gleitstückes weisen; und eine große Anzahl von Kugeln aufweisen, welche in endlosen Bahnen im Gleitstück sich bewegen und zwischen den oberen Wälzflächen des Gleitstücks und den unteren Gleitflächen der Schienenbahn und zwischen den unteren Wälzflächen des Gleitstücks und den oberen Wälzflächen der Schienenbahn zur Lastaufnahme vorgesehen sind.

Nach der Erfindung wird der horizontale Abschnitt des Gleitstücks in Richtung nach oben durch die Kugel in Reihen abgestützt, welche sich auf den zwei oder mehr Kugelwälzflächen abwälzen, die nach unten weisen und in der Nähe des Mittelteils der inneren Seite vorgesehen sind, so daß das Mittelteil des horizontalen Abschnittes durch eine Belastung nicht nach unten ausgelenkt bzw. verformt wird. Bei dem linearen Bewegungslager, auf welches sich die Erfindung bezieht, ist es daher möglich, in positiver Weise die Breiten des Gleitstücks und der Schienenbahn größer zu machen, und daher lassen sich ein Leistungsvermögen und eine Steifigkeit gegenüber einem Belastungsmoment des Lagers beträchtlich verbessern.

Da das Mittelteil des horizontalen Abschnitts des Gleitstücks nicht nach unten verformt wird, läßt sich die Dicke des horizontalen Abschnitts des Gleitstücks im Vergleich zu dem linearen Bewegungslager nach dem Stand der Technik kleiner machen, und somit läßt sich die Höhe des Lagers insgesamt verkleinern. Ferner ist nur eine Kugelwälzfläche, welche nach unten weist, an dem Randabschnitt des Gleitstückes ausgebildet, und die nach unten weisenden Kugelwälzflächen sind in der Nähe des Mittelteils des horizontalen Abschnitts des Gleitstücks ausgebildet. Daher läßt sich die Länge des Randabschnittes reduzieren, ohne daß man wechselseitige Behinderungen zwischen den Kugeln erhält, welche sich auf den oberen und unteren Kugelwälzflächen abwälzen, wodurch sich auch die Höhe des Lagers reduzieren läßt.

Da wie vorstehend angegeben ist, die Höhe des linearen Bewegungslagers nach der Erfindung beträchtlich herabgesetzt werden kann, läßt sich die Steifigkeit gegenüber einem Belastungsmoment beträchtlich erhöhen.

Da das Mittelteil des horizontalen Abschnitts des Gleitstücks sich nicht nach unten verformt, wenn eine Belastung hierauf einwirkt, verlaufen die Randabschnitte des Gleitstückes nicht divergierend nach außen und daher läßt sich die große Steifigkeit gegenüber der Belastung in jeglicher Richtung einhalten.

Weitere Einzelheiten, Merkmale und Vorteile der Erfindung ergeben sich aus der nachstehenden Beschreibung von bevorzugten Ausführungsformen unter Bezugnahme auf die beigefügte Zeichnung.

Darin zeigt:

Fig. 1 eine Schnittansicht zur Verdeutlichung einer ersten bevorzugten Ausführungsform eines linearen Bewegungslagers nach der Erfindung,

Fig. 2 eine Draufsicht auf ein lineares Bewegungslager nach einer ersten Ausführungsform der Erfindung,

Fig. 3 eine Schnittansicht zur Verdeutlichung einer zweiten bevorzugten Ausführungsform eines linearen Bewegungslagers nach der Erfindung,

Fig. 4 eine Draufsicht auf ein lineares Bewegungslager gemäß einer zweiten bevorzugten Ausführungsform nach der Erfindung,

Fig. 5 eine Ansicht zur Verdeutlichung der Verteilung einer Reaktionskraft und der Verformung eines Gleitstückes, wenn Belastungen in verschiedenen Richtungen auf das lineare Bewegungslager gemäß der zweiten bevorzugten Ausführungsform einwirken,

Fig. 6 eine Schnittansicht zur Verdeutlichung eines linearen Bewegungslagers einer üblichen Bauform, und

Fig. 7 eine Draufsicht auf ein lineares Bewegungslager gemäß einer üblichen Bauform.

Ein lineares Bewegungslager bzw. ein lineares Gleitlager nach der Erfindung wird nachstehend unter Bezugnahme auf die Zeichnungen näher erläutert.

Die **Fig.** 1 und 2 zeigen ein lineares Bewegungslager gemaß einer ersten bevorzugten Ausführungsform nach der Erfindung. Das lineare Bewegungslager gemäß dieser bevorzugten Ausführungsform wird von einer Schienenbahn **20** gebildet, welche fest mit einer Bezugsfläche mit Hilfe von nicht dargestellten Befestigungsschrauben in mehreren Reihen verbunden ist sowie von einem Gleitstück **10**, welches auf der Schienenbahn angeordnet ist, und mit einer großen Anzahl Kugeln **30**, welche zwischen dem Gleitstück **10** und der Schienenbahn **20** angeordnet sind, und dazu dienen, das Gleitstück **10** in einer axialen Richtung zu der Schienenbahn **20** (senkrecht zur Zeichenebene in **Fig.** 1) gleitbeweglich zu führen.

Die Schienenbahn **20** hat einen etwa länglichen Querschnitt, welcher eine Breite hat, die größer als die Höhe ist. Die Schienenbahn ist an jeder Seitenfläche mit einer Kugelwälzfläche **21** versehen, welche axial verläuft und nach unten weist, und sie ist auch in der Nähe des Mittelteils der oberen Fläche mit zwei Kugelwälzflächen **22** versehen, welche axial verlaufen und nach oben weisen. Diese nach unten und oben gerichteten Kugelwälzflächen **21** und **22** sind in Querrichtung symmetrisch zueinander bezüglich eines Schnittes C-C angeordnet, welche eine Achse der Schienenbahn **20** enthält. Bei dieser ersten bevorzugten Ausführungsform ist ein Abstand L_1 zwischen der Kugelwälzfläche **21** und dem Schnitt C-C etwa doppelt so lang als ein Abstand L_2 zwischen der nach oben weisenden Kugelwälzfläche **22** und dem Schnitt C-C. Jede Kugelwälzfläche **21** und **22** bildet eine einzige, pumpenförmige Ausnehmung, welche einen Krümmungsradius hat, welcher etwa gleich einem Krümmungsradius der Kugel **30** ist. Mit dem Bezugszeichen **23** werden Befestigungsöffnungen bezeichnet, durch die sich Befestigungsschrauben einsetzen lassen.

Das Gleitstück **10** wird von einem Lagerblock **11** gebildet, welcher aus Metall hergestellt ist und einem Paar von endseitigen Kappen **12**, welche aus Kunststoff hergestellt sind, und die an den gegenüberliegenden Endflächen des Blockes **11** fest angebracht sind. Der Lagerblock **11** hat eine kanalähnliche Gestalt und umfaßt einen horizontalen Abschnitt **11a** und ein Paar von Randabschnitten **11b**, welche von den gegenüberliegenden Seitenrändern des Abschnitts **11a** nach unten verlaufen. Ferner hat er auch eine kanalförmige Ausnehmung **11c**, welche über der Schienenbahn **20** liegt und komplementär zu der Gestalt der Schiene **20** ausgelegt ist. Jeder Randabschnitt **11b** ist an seiner inneren Seite mit einer nach oben weisenden Kugelwälzfläche **13** versehen, welche der nach unten weisenden Kugelwälzfläche **21** auf der Schienenbahn **20** zugewandt ist. Der horizontale Abschnitt **11a** ist in der Nähe des Mittelteils der inneren Seite mit zwei Kugelwälzflächen **14** versehen, welche in Richtung auf die nach unten weisenden Kugelwälzflächen **22** der Schienenbahn **20** weisen. Diese Kugelwälzflächen **13** und **14** bilden einzelne, bogenförmige Ausnehmungen ähnlich wie die Kugelwälzflächen **21** und **22** der Schienenbahn **20**.

Die zugeordneten Kugelwälzflächen **13** und **14** sind in Querrichtung symmetrisch bezüglich des Schnitts C-C angeordnet, welche die Achse des Lagerblocks **11** enthält. Bei dieser bevorzugten Ausführungsform ist ein Abschnitt L_1 zwischen der nach oben gerichteten Kugelwälzfläche **13** des Randabschnitts **11b** und des

Schnitts C-C etwa doppelt so groß als ein Abschnitt L_2 zwischen der nach unten weisenden Kugelwälzfläche **14** des horizontalen Abschnitts **11**a und des Schnitts C-C. Dieser Zusammenhang von $L_1 = 2L_2$ wird bestimmt, um die Verformung bzw. Auslenkung des horizontalen Abschnitts **11**a nach unten so klein wie möglich zu machen, wenn eine nach unten wirkende Belastung auf den Lagerblock **11** einwirkt. Diese Bestimmung erfolgt aufgrund von mechanischen Berechnungen, bei denen der horizontale Abschnitt als ein an bei den Enden abgestützter Balken angenommen wird.

Bei dieser bevorzugten Ausführungsform ist nur eine Kugelwälzfläche **13**, welche nach oben weist, an dem Randabschnitt **11**b des Lagerblocks **11** ausgebildet, und die nach unten weisenden Kugelwälzflächen **14** sind in der Nähe des Mittelteils des horizontalen Abschnittes **11**a ausgebildet. Selbst wenn daher die Länge des Randabschnitts **11**b kurz bemessen ist, behindern die Kugeln **30**, welche sich auf der nach oben weisenden Kugelwälzfläche **13** abwälzen, nicht die Kugeln **30**, welche sich auf der nach unten weisenden Kugelwälzfläche **14** abwälzen. Folglich lassen sich die Höhen des Lagerblocks **11** und somit des Gleitstücks **10** kleiner machen.

Ferner sind die Kugeln **30** zwischen der nach unten weisenden Kugelwälzfläche **21** der Schienenbahn **20** und der nach oben weisenden Kugelwälzfläche des Lagerblocks **11** oder zwischen der nach oben weisenden Kugelwälzfläche **22** der Schienenbahn **20** und der nach unten weisenden Kugelwälzfläche **14** des Lagerblocks **11** eingespannt und wälzen sich auf diesen Wälzflächen während der Lastaufnahme ab.

Bei dieser Arbeitsweise schließt eine Kontaktrichtung der Kugel **30** zu der nach oben weisenden Kugelwälzfläche **13** des Randabschnitts **11**b, d. h. in eine Richtung der Kugelkontaktlinie, etwa einen Winkel von 45° zur Horizontalen ein. Auch schließt eine Richtung der Kugelkontaktlinie an der nach unten weisenden Kugelwälzfläche **14** des horizontalen Abschnittes **11**a etwa einen Winkel von 45° zur horizontalen Richtung ein.

Somit kann das lineare Bewegungslager gemäß dieser bevorzugten Ausführungsform die Belastung gleichmäßig in vertikaler Richtung und in Querrichtung tragen. Vorausgesetzt, daß die Richtung der Kugelkontaktlinie an den jeweiligen Kugelwälzflächen **13** und **14** zur Horizontalen in einem Bereich von $45 \pm 10°$ liegt, kann das lineare Bewegungslager die Belastung im wesentlichen gleichförmig in den vier Richtungen tragen.

Kugelaustrittsöffnungen **15**, welche den Kugelwälzflächen **13** und **14** zugeordnet sind, durchsetzen in axialer Richtung die massiven Teile der Randabschnitte **11**b und des horizontalen Randabschnittes **11**a. Die gegenüberliegenden Enden jeder Kugelaustrittsöffnung **15** sind in den Enden der zugeordneten Kugelwälzflächen über Kugelrückausnehmungen (nicht gezeigt) bzw. Kugelrücklaufkanäle verbunden, so daß die Kugeln **30** endlos über die Kugelwälzflächen und die Kugelaustrittsöffnungen **15** laufen.

Kugelhalter **40**, **41** und **42**, welche von Stahlplatten gebildet werden, sind an den Enden der inneren Flächen der Randabschnitte **11**b und der unteren Fläche des horizontalen Randabschnittes **11**a des Lagerblocks **11** vorgesehen, so daß ein Herausfallen der Kugel **30** verhindert werden kann, wenn das Gleitstück bzw. der Schlitten **10** von der Schienenbahn **20** abgenommen wird. Diese Halter **40**, **41** und **42** sind fest mit dem Lagerblock **11** beispielsweise mit Hilfe von Schrauben verbunden.

Der horizontale Abschnitt **11**a des Lagerblocks **11** ist an den gegenüberliegenden Seitenteilen und am Mittelteil mit Befestigungsflächen **17** und **18** zum Anbringen eines Tisches versehen. Die Montagefläche **17** an jeder Seite ist mit zwei Befestigungsöffnungen **16** versehen. Somit läßt sich das Gleitstück **10** an dem Tisch mit Hilfe von vier Schrauben festlegen. Bei der Erfindung ist es nicht erforderlich, eine Befestigungsöffnung im Mittelteil der Befestigungsfläche **18** des horizontalen Abschnittes **11**a vorzusehen. Der horizontale Abschnitt **11**a wird von der Unterseite mittels Kugeln **30** abgestützt, welche zwischen den nach oben weisenden Kugelwälzflächen **22** der Schienenbahn **20** und den nach unten weisenden Kugelwälzflächen **14** des horizontalen Abschnittes **11**a sich abwälzen. Hierdurch erhält man eine Konstruktion, welche die Fähigkeit hat, daß Verformungen bzw. Auslenkungen des Mittelteils des horizontalen Abschnittes **11**a verhindert oder wesentlich vermindert werden. Da bei der dargestellten Ausführungsform die Kugeln **30** den horizontalen Abschnitt **11**a in Richtung nach oben unterstützen, kann der horizontale Abschnitt **11**a eine kleine Dicke haben, ohne daß Verformungen bzw. Auslenkungen zu befürchten sind.

Die **Fig.** 3 und 4 zeigen eine bevorzugte Ausführungsform nach der Erfindung. Bei dem linearen Bewegungslager gemäß dieser Ausführungsform sind Befestigungsöffnungen **19** zum Anbringen des Tisches an Stellen in der Nähe des Mittelteils des horizontalen Abschnittes **11**a des Lagerblocks **11** vorgesehen. Die weiteren Einzelheiten dieser Auslegungsform sind ähnlich wie bei der ersten bevorzugten Ausführungsform ausgelegt und werden daher nachstehend nicht nochmals näher beschrieben.

Wenn Belastungen in verschiedenen Richtungen auf das lineare Bewegungslager nach der Erfindung einwirken, werden Reaktionskräfte in verschiedenen Richtungen und Verformungen des Lagerblocks **11** wie nachstehend beschrieben hervorgerufen.

a) Wenn das Gleitstück **10** eine nach unten wirkende Belastung (1) aufnimmt, und wenn der Tisch T eine nach unten gerichtete Belastung P auf das Gleitstück **10** aufbringt, wird die Belastung P in den Befestigungsflächen **17** und **18** des Lagerblocks **11** verteilt, wie dies in **Fig.** 5(a) gezeigt ist und man erhält eine gleichmäßige Verteilungsbelastung P_1 und P_2, welche jeweils auf die Befestigungsflächen **17** und **18** wirken, wobei $P = 2P_1 + P_2$.

(2) Die Kugeln, welche die Belastungen tragen, sind Kugeln (wie dies mit durchgezogenen schwarzen Kreisen in der Figur dargestellt ist), welche auf den nach unten gerichteten Kugelwälzflächen **14** des Lagerblocks **11** eine Abwälzbewegung ausführen. Da diese Kugeln in der Nähe des Mittelteils des horizontalen Abschnittes **11**a liegen, welcher die Belastung trägt, wird der horizontale Abschnitt **11**a durch die Belastung P_2, welche auf die Befestigungsfläche **18** wirkt, nicht verformt oder ausgelenkt und daher haben beide Randabschnitte **11**b keinen nach außen divergierenden Verlauf. Daher erhält man bei dem linearen Bewegungslager nach der Erfindung eine gleichbleibende ausreichende Steifigkeit gegenüber einer nach unten wirkenden Belastung.

b) Wenn das Gleitstück **10** eine nach oben gerichtete Belastung (1) aufnimmt, und wenn der Tisch T die nach oben gerichtete Belastung P gegen das Gleitstück **10** zur Wirkung bringt, wirkt diese Belastung P auf den Lagerblock **11** als eine Belastung P_0, welche über die Schrauben übertragen wird, wie dies in

Fig. 5(b) gezeigt ist, wobei $P = P_0 + P_0$ gilt.

(2) Die Kugeln, welche die Belastungen tragen, sind Kugeln (wie dies mit durchgezogenen schwarzen Kreisen in der Figur verdeutlicht ist), welche eine Abwälzbewegung auf den Kugelwälzflächen **13** des Lagerblocks **11** ausführen. Wenn diese Kugeln die Belastung tragen, versuchen die Randabschnitte **11**b in Richtung nach hinten einen divergierenden Verlauf einzunehmen und gleichzeitig versucht das Mittelteil des horizontalen Abschnittes **11**a sich in Richtung nach unten zu verformen bzw. auszulenken. Da jedoch der horizontale Abschnitt **11**a in Richtung nach oben durch die Kugeln abgestützt ist, welche eine Abwälzbewegung auf den nach unten weisenden Kugelwälzflächen **14** ausführen, wird der horizontale Abschnitt **11**a nicht nach unten verformt. Als Folge hiervon läßt sich die Verschiebung bzw. Verformung der Randabschnitte **11**b unterdrücken. Somit behält das lineare Bewegungslager nach der Erfindung eine ausreichende Steifigkeit gegenüber einer nach oben gerichteten Belastung bei.

c) Wenn das Gleitstück **10** die Querbelastungen (**1**) aufnimmt und wenn der Tisch T die Querbelastung P auf das Gleitstück **10** aufbringt, wird diese Belastung P in die Belastungen P_3, welche auf die Befestigungsflächen **17** des Lagerblocks **11** wirken, aufgeteilt, wie dies in **Fig.** 5(c) gezeigt ist, wobei $P = P_3 + P_3$ gilt.

(2) Die Kugeln, welche die Belastungen tragen, sind Kugeln (wie dies mit durchgezogenen schwarzen Kreisen dargestellt ist), welche eine Abwälzbewegung auf der nach oben weisenden Kugelwälzfläche **13** ausführen, welche am linken Randabschnitt **11**b ausgebildet sind und auf der nach unten weisenden Kugelwälzfläche **14** ausführen, welche auf der rechten Seite im horizontalen Abschnitt **11**a vorgesehen ist.

(3) Zuerst soll eine Beschreibung der bisher üblichen Kugeln erfolgen. Wenn diese Kugeln die Belastung aufnehmen, versucht der linke Randabschnitt **11**b sich in Richtung nach außen zu verformen bzw. auszulenken, wie dies mit einem Pfeil verdeutlicht ist und zugleich versucht das Mittelteil des horizontalen Abschnittes **11**a sich in ähnlicher Weise wie beim vorstehend genannten Fall (b) nach unten zu verformen bzw. auszulenken. Da jedoch der horizontale Abschnitt **11**a in Richtung nach oben durch die Kugeln abgestützt ist, welche eine Abwälzbewegung auf den nach unten weisenden Kugelwälzflächen **14** ausführen, kann sich der horizontale Abschnitt **11**a nicht nach unten verformen bzw. auslenken. Als Folge hiervon läßt sich die Verlagerung des Randabschnittes **11**b unterdrücken.

(4) Dann erfolgt eine Beschreibung der rechten Kugeln. Wenn diese Kugeln die Querbelastung aufnehmen, bewirkt die Reaktionskraft hiervon, daß das Mittelteil des horizontalen Abschnittes **11**a nach oben gedrückt wird. Jedoch ist das Mittelteil des horizontalen Abschnittes **11**a in Kontakt mit dem Tisch T über die Befestigungsfläche **18** des Lagerblocks **11** und kann sich somit durch die Belastung nicht nach oben verformen. Auf diese Weise läßt sich eine Verlagerung des Randabschnittes **11**b unterdrücken.

Somit erhält man bei den linearen Bewegungslagern nach der Erfindung eine konstante ausreichende Steifigkeit gegenüber der Querbelastung.

Die Richtungen der Kugelkontaktlinien in den oberen Kugelwälzflächen **13** und den unteren Kugelwälzflächen **14**, welche im Lagerblock **11** ausgebildet sind, sind nicht auf jene Größenangaben beschränkt, welche zuvor in Zusammenhang mit den bevorzugten Ausführungsformen erläutert wurden. Vielmehr lassen sich diese in beliebiger Weise nach Maßgabe der Richtungen der mit Hilfe des Lagers aufzunehmenden Belastungen bestimmen. Beispielsweise kann die Richtung der Kugelkontaktlinie in der nach unten weisenden Kugelwälzfläche **14** einen Winkel von 90° zur horizontalen Richtung einschließen und die Richtung der Kugelkontaktlinie in der nach oben gerichteten Wälzfläche **13** kann einen Winkel von etwa 30° zur horizontalen Richtung einschließen.

Obgleich hier die vorliegende Erfindung anhand von bevorzugten Ausführungsformen erläutert wurde, ist die Erfindung natürlich nicht auf die dort beschriebenen Einzelheiten beschränkt, sondern sind zahlreiche Abänderungen und Modifikationen möglich, die der Fachmann im Bedarfsfall treffen wird, ohne den Schutzgedanken nach der Erfindung zu verlassen.

Patentansprüche

1. Lineares Bewegungslager, **gekennzeichnet durch**:
   - ein Gleitstück (**10**) mit einer kanalähnlichen Gestalt, welches einen horizontalen Abschnitt (**11**a) und ein Paar von Randabschnitten (**11**b) hat, die sich von den gegenüberliegenden Seiten des horizontalen Abschnitts (**11**a) weg erstrecken, wobei eine Kugelwälzfläche (**13**), welche nach oben weist, an einer inneren Seite jedes Randabschnitts (**11**b) ausgebildet ist, und wenigstens zwei Kugelwälzflächen (**14**), welche nach unten weisen, in der Nähe eines Mittelteils einer inneren Fläche des horizontalen Abschnittes (**11**a) ausgebildet sind;
   - eine Schienenbahn (**20**), auf welcher das Gleitstück (**10**) angeordnet ist, wobei die Schienenbahn (**20**) an ihren gegenüberliegenden Seitenflächen mit Kugelwälzflachen (**21**, **22**) versehen ist, welche nach unten in Richtung auf die nach oben gerichteten Kugelwälzflächen (**13**) des Gleitstücks (**10**) weisen und die an ihrer oberen Fläche mit Kugelwälzflächen (**22**) versehen ist, welche nach oben in Richtung auf die nach unten weisenden Kugelwälzflächen (**14**) des Gleitstücks (**10**) weisen; und
   - eine grobe Anzahl von Kugeln (**30**), welche sich längs endlosen Bahnen im Gleitstück (**10**) bewegen und zwischen den nach oben weisenden Wälzflächen (**13**) des Gleitstücks (**10**) und den nach unten Wälzflächen (**21**) der Schienenbahn (**20**) und zwischen nach unten weisenden Wälzflächen (**14**) des Gleitstücks (**10**) und den nach oben weisenden Wälzflächen (**22**) der Schienenbahn (**20**) zur Aufnahme einer Belastung angeordnet sind.

2. Lineares Bewegungslager nach Anspruch 1, dadurch gekennzeichnet, daß die Richtungen der Kugelkontaktlinien in den nach oben weisenden Kugelwälzflächen (**13**) und den nach unten weisenden Kugelwälzflächen (**14**) des Gleitstücks (**10**) einen Winkel von $45 \pm 10°$ bezüglich der horizontalen Richtung bilden.

3. Lineares Bewegungslager nach Anspruch 1, dadurch gekennzeichnet, daß ein horizontaler Abstand zwischen der nach oben weisenden Kugelwälzfläche (**13**) des Gleitstücks (**10**) und einer Achse des Lagers doppelt so groß als sein horizontaler Abstand zwischen der nach unten weisenden Kugelwälzfläche (**14**) des Gleitstücks (**10**) und der Achse des Lagers ist.
4. Lineares Bewegungslager nach Anspruch 1, dadurch gekennzeichnet, daß ein Abstand in einer Höhenrichtung zwischen der nach oben weisenden Kugelwälzfläche (**13**) und der nach unten weisenden Kugelwälzfläche (**14**) des Gleitstücks (**10**) im wesentlichen gleich oder kleiner als ein Durchmesser der Kugel (**30**) ist.

(54) Hin- und hergehender Tisch und zugehörige Führungsvorrichtung zur gleichmäßigen Lagerung einer Last in vier Richtungen

(57) Es wird eine Führungsvorrichtung zur Lagerung einer Last in vier Richtungen angegeben, welche eine verbesserte Steifigkeit gegenüber einer vertikalen, einer horizontalen oder einer Momentenlast hat, um hierdurch eine verbesserte Positioniergenauigkeit eines Lagerkörpers relativ zu einer Führungsbahn während einer hin- und hergehenden Bewegung beizubehalten. Jede der Kugelwälzflächen wenigstens auf der Führungsbahn und/oder des Lagerkörpers wird von einer Ausnehmung gebildet, welche einen gotischen Bogen im Querschnitt beschreibt und zwei gekrümmte Flächen umfaßt, welche miteinander verbunden sind, und die derart angeordnet ist, daß eine vertikale oder horizontale Last, welche auf die Führungsvorrichtung einwirkt, auf die eine oder die andere der gekrümmten Flächen im wesentlichen in die Richtung wirken kann, in welcher die Last auf die Führungsvorrichtung einwirkt.

DE 42 15 692 A 1

Beschreibung

Die Erfindung befaßt sich mit einer Führungsvorrichtung für die gleichmäßige Lagerung bzw. Abstützung einer Last in vier Richtungen, welche beispielsweise an Gleitflächen eines Tischschlittens oder einem Bearbeitungscenter in einer Werkzeugmaschine eingesetzt wird, oder bei jenem Teil einer Fördervorrichtung eingesetzt wird, welche einen schweren Gegenstand trägt und eine hin- und hergehende Bewegung ausführt, sowie bei einem hin- und hergehenden Tisch eingesetzt wird, welcher eine derartige Führungsvorrichtung umfaßt.

Eine bekannte Führungsvorrichtung zur gleichmäßigen Lagerung einer Last in vier Richtungen ist in JP-C-38 812/1982 angegeben. In **Fig.** 11 der beiliegenden Zeichnungen ist insgesamt mit 40 eine derartige Führungsvorrichtung gezeigt und weist eine Führungsbahn 42 auf, welche zwei Kugelwälzflächen 44 hat, die jeweils in einem Paar von gegenüberliegenden Seiten ausgebildet sind, ferner einen Lagerkörper 46 aufweist, welcher eine konkave Ausnehmung 50 zur passenden Aufnahme der Führungsbahn 42 besitzt und an seiner Innenfläche insgesamt mit vier Kugelwälzflächen 48 versehen ist, welche jeweils einer der Kugelwälzflächen 44 der Führungsbahn 42 zugewandt sind, und eine Mehrzahl von Kugeln 52 aufweist, welche zwischen den Kugelwälzflächen 44 der Führungsbahn 42 und den zugeordneten Kugelwälzflächen 48 des Lagerkörpers 46 gehalten sind.

Jede Kugelwälzfläche 44 und 48 wird von einer Ausnehmung gebildet, welche in Form eines einzigen Bogens im Querschnitt ausgelegt ist und einen Krümmungsradius hat, welcher im wesentlichen gleich dem Radius der Kugeln 52 bemessen ist. Die Kugeln 52 und die Kugelwälzflächen 44 und 48 bilden Lastwirklinien 42, welche jeweils einen Winkel von 45° zur Horizontalen haben.

Fig. 12 zeigt eine weitere bekannte Führungsvorrichtung für die gleichmäßige Lagerung einer Last in vier Richtungen, welche in JP-U-24 258/1988 angegeben ist. Die Führungsvorrichtung weist eine Führungsbahn 62 auf, welche Kugelwälzflächen 64 hat, ferner einen Lagerkörper 66, welcher Kugelwälzflächen 68 hat, und Kugeln 72 auf, welche dazwischen gehalten sind. Jede Kugelwälzfläche 64 der Führungsbahn 62 wird von einer Ausnehmung gebildet, welche in Form eines gotischen Bogens im Querschnitt ausgestaltet ist und zwei gekrümmte Flächen 64a und 64b umfaßt, welche miteinander verbunden sind. In ähnlicher Weise wird jede Kugelwälzfläche 68 des Lagerkörpers 66 von einer Ausnehmung gebildet, die in Form eines gotischen Bogens im Querschnitt ausgestaltet ist und zwei gekrümmte Flächen 68a und 68b umfaßt, welche miteinander verbunden sind. Die Kugeln 72 und die Kugelwälzflächen 64 und 68 bilden Lastwirklinien, welche jeweils einen Winkel von 56° zur Horizontalen einschließen, wie dies bei der Vorrichtung in **Fig.** 11 der Fall ist.

Da jedoch die Lastwirklinien unter einem Winkel von 45° zur Horizontalen liegen, ist die in **Fig.** 11 gezeigte Vorrichtung zu wenig steif gegenüber einer Momentanlast, welche bei einem einachsigen Einsatz in geeigneter Weise auftreten kann, obgleich diese Führungsvorrichtung die Fähigkeit hat, jegliche auf dieselbe in vertikaler oder horizontaler Richtung wirkende Last gleichmäßig zu lagern bzw. aufzunehmen. Darüber hinaus kann es leicht vorkommen, daß eine auf die Führungsvorrichtung in vertikaler oder horizontaler Richtung wirkende Last zu einer Veränderung der Kontaktpunkte zwischen den Kugeln und den Kugelwälzflächen führen kann, und hierdurch kann es vorkommen, daß der Lagerkörper in Richtung der Last und von der genauen Position relativ zur Führungsbahn sich verlagern kann.

Die in **Fig.** 12 gezeigte Führungsvorrichtung hat in ähnlicher Weise diesen Nachteil, welcher auf die Lastwirklinien zurückzuführen ist, welche unter einem Winkel von 45° zur Horizontalen liegen. Eine in vertikaler oder horizontaler Richtung wirkende Last kann in ähnlicher Weise leicht dazu führen, daß der Lagerkörper von der genauen Position relativ zur Führungsbahn wegverlagert wird.

Wenn eine Führungsvorrichtung mit dieser betreffenden Bauart eingesetzt wird, ist ihre Führungsbahn an einem Bett festgelegt, und der Lagerkörper ist ein Tisch. Die Führungsvorrichtung wird eingesetzt, um die hin- und hergehende Bewegung des Tisches längs des Bettes auf einer Geraden zu führen. Keine genaue hin- und hergehende Bewegung des Tisches läßt sich jedoch bei einer der bekannten Führungsvorrichtungen erreichen, da die einwirkende Last zu einer Verlagerung des Lagerkörpers führen kann, wie dies vorstehend angegeben ist. Eine Werkzeugmaschine, welche einen solchen Tisch mit einer derartigen Führungsvorrichtung umfaßt, kann daher leicht einen nennenswerten Maßfehler bei der Bearbeitung eines Werkstückes verursachen.

Unter den vorstehend geschilderten Umständen zielt die Erfindung hauptsächlich darauf ab, eine Führungsvorrichtung zur gleichmäßigen Lastaufnahme in vier Richtungen bereitzustellen, welche eine ausreichend verbesserte Steifigkeit gegen jegliche Momentanlast hat und für einen einachsigen Einsatz geeignet ist, und die eine drastisch verbesserte Genauigkeit hinsichtlich der Relativpositionen eines Lagerkörpers und einer Führungsbahn in Richtung einer beliebigen einwirkenden Last hat.

Ferner bezweckt die Erfindung, einen hin- und hergehenden Tisch bereitzustellen, welcher eine genaue hin- und hergehende Bewegung ausführen kann.

Nach der Erfindung wird dies mittels einer gleichmäßigen Führungsvorrichtung für eine Last in vier Richtungen erreicht, welche eine Führungsbahn aufweist, die eine Mehrzahl von Kugelwälzflächen hat, welche auf der äußeren Fläche ausgebildet sind, einen Lagerkörper aufweist, welcher eine konkave Ausnehmung zur passenden Aufnahme der Führungsbahn besitzt, und an seiner Innenfläche mit einer Mehrzahl von Kugelwälzflächen versehen ist, die jeweils einer der Kugelwälzflächen an der Führungsbahn zugewandt sind, und eine Mehrzahl von Kugeln aufweist, die zwischen den Kugelwälzflächen und der Führungsbahn und den zugeordneten Kugelwälzflächen am Lagerkörper gehalten sind, wobei die jeweilige Kugelwälzfläche wenigstens auf der Führungsbahn oder dem Lagerkörper von einer Ausnehmung gebildet wird, welche in Form eines gothischen Bogens im Querschnitt gestaltet ist und zwei gekrümmte Flächen umfaßt, die miteinander verbunden sind, wobei diese gekrümmten Flächen derart angeordnet sind, daß eine vertikale und eine horizontale Last, die auf die Führungsvorrichtung einwirkt, auf die gekrümmten Flächen jeweils längs Linien einwirken kann, welche in jene Richtungen verlaufen, die im wesentlichen gleich den Richtungen der jeweiligen Lasten sind, die auf der Führungsvorrichtung abgestützt werden.

Die weitere Zielsetzung nach der Erfindung wird durch einen hin- und hergehenden Tisch verwirklicht, welcher ein Bett aufweist, eine Mehrzahl von im wesentlichen parallelen, linearen Führungsvorrichtungen aufweist, welche auf dem Bett vorgesehen sind, und einen Tisch aufweist, welcher derart beschaffen und ausgelegt ist, daß er durch die linearen Führungsvorrichtungen zur Ausführung einer hin- und hergehenden Bewegung auf einer geraden Linie des Bettes geführt ist, wobei jede der linearen Führungsvorrichtungen eine Führungsbahn aufweist, welche fest mit dem Bett verbunden ist, und eine Mehrzahl von Kugelwälzflächen hat, welche auf der äußeren Fläche ausgebildet sind, einen Lagerkörper aufweist, welcher fest mit dem Tisch verbunden ist, und welcher eine konkave Ausnehmung zur passenden Aufnahme der Führungsbahn hat und an seiner inneren Fläche mit einer Mehrzahl von Kugelwälzflächen versehen ist, welche jeweils einer der Kugelwälzflächen auf der Führungsbahn zugewandt sind, und eine Mehrzahl von Kugeln aufweist, welche zwischen den Kugelwälzflächen auf der Führungsbahn und den zugeordneten Kugelwälzflächen an dem Lagerkörper gehalten sind, wobei eine der linearen Führungsvorrichtungen eine Führungsvorrichtung der vorstehend genannten Art zur Lagerung einer Last in vier Richtungen ist und die restlichen Führungsvorrichtungen radiale Lastführungen zur Lagerung von lediglich einer vertikalen Last sind.

Es ist wesentlich, daß jede der Kugelwälzflächen wenigstens der Führungsbahn oder des Lagerkörpers bei der Führungsvorrichtung zur Lagerung in vier Richtungen nach der Erfindung von einer Ausnehmung gebildet wird, welche in Form eines gothischen Bogens im Querschnitt gestaltet ist. Die Kugelwälzflächen auf der Führungsbahn können von Ausnehmungen gebildet werden, welche in Form eines gothischen Bogens im Querschnitt gestaltet sind, während die Kugelwälzflächen am Lagerkörper von außen gebildet werden können, die in Form eines einzigen Bogens im Querschnitt ausgebildet sind, oder die Auslegung auch umgekehrt getroffen werden kann. Alternativ können alle Kugelwälzflächen an der Führungsbahn und dem Lagerkörper von Ausnehmungen gebildet werden, welche im Querschnitt eine gothische Gestalt haben (diese werden nachstehend zur Vereinfachung lediglich bezeichnet mit "Ausnehmungen mit gothischem Bogen").

Jede von einer Ausnehmung mit gothischem Bogen gebildete Kugelwälzfläche umfaßt zwei gekrümmte Flächen, welche miteinander verbunden sind und welche derart angeordnet sind, daß eine Last im wesentlichen vertikal oder horizontal auf die jeweiligen gekrümmten Flächen wirken kann. Diese Auslegung ermöglicht, daß die jeweilige gekrümmte Fläche eine große vertikale oder horizontale Last abstützen kann, da die Richtungen der Linien, längs denen die vertikalen und horizontalen Lasten auf die Führungsvorrichtung wirken, auf die gekrümmten Flächen wirken und im wesentlichen gleich wie die Richtungen der auf die Führungsvorrichtung wirkenden Lasten gerichtet sind. Somit kann die Führungsvorrichtung nach der Erfindung eine große Momentanlast aufnehmen, und sie ist ausreichend starr gegenüber jeglicher Momentanlast bei einem einachsigen Einsatz.

Die Auslegung der gekrümmten Flächen gemäß der voranstehenden Beschreibung ermöglicht auch, daß jegliche Positionsänderung auf ein Minimum eingestellt oder verhindert wird, die ansonsten bei einer auf die Führungsvorrichtung wirkenden Last zu Punktkontakten zwischen den Kugeln und den gekrümmten Flächen führen könnte, da die Tangentenlinien, die durch die Kontaktpunkte gehen, im wesentlichen senkrecht zur Richtung der Last sind. Hierdurch erhält man eine drastisch verbesserte Genauigkeit hinsichtlich der vertikalen oder horizontalen Positionierung des Lagerkörpers relativ zur Führungsbahn.

Der hin- und hergehende Tisch nach der Erfindung umfaßt eine Führungsvorrichtung nach der Erfindung für Lasten in vier Richtungen als eine der linearen Führungsvorrichtungen, welche die Bewegung des Tisches auf einer Geraden führen. Daher ist es möglich, jegliche Verlagerung des Tisches in Richtung einer vertikalen oder horizontalen Last, die hierauf einwirkt, auf ein Minimum einzustellen oder zu verhindern, und hierdurch läßt sich die Bearbeitungsgenauigkeit beispielsweise in einer Werkzeugmaschine drastisch verbessern, bei welcher der Tisch nach der Erfindung eingesetzt wird.

Die restlichen linearen Führungen sind Radiallastführungsvorrichtungen oder Führungseinrichtungen. Die Radiallastführungsvorrichtung ist eine lineare Führung, welche nur eine vertikale Last aufnimmt und kaum eine horizontale Last abstützt. Jede der Kugelwälzflächen auf dem Lagerkörper und der Führungsbahn kann von einer Ausnehmung gebildet werden, die in Form eines einzigen Bogens im Querschnitt ausgestaltet ist (nachstehend wird dies der Einfachheit halber bezeichnet mit "Ausnehmung mit einem einzigen Bogen"), und sie umfaßt eine einzige gekrümmte Fläche, wenn die Richtung einer Linie, längs welcher eine Last auf die gekrümmte Fläche einwirkt, gleich der Richtung einer vertikalen Lastaufnahme an der Führungsvorrichtung ist.

Aus den nachstehend näher angegebenen Gründen wird daher nur für eine der linearen Führungen eine Lastführungsvorrichtung für vier Richtungen eingesetzt, während die restlichen als radiale Lastführungen oder -führungsvorrichtungen ausgelegt sind.

Wenn in einem System, welches eine Mehrzahl von parallelen linearen Führungen zur Führung der hin- und hergehenden Bewegung eines Tisches relativ zu einem Bett umfaßt, sind die Führungen nicht parallel oder wenn irgendeine Wärmedehnungsdifferenz zwischen dem Tisch und dem Bett auftritt, kann es leicht vorkommen, daß sich die Lagerkörper relativ zu den Führungsbahnen horizontal verlagern und hierdurch eine starke Zunahme hinsichtlich des Wälzwiderstandes der Kugeln auftritt. Wenn alle linearen Führungsvorrichtungen Führungsvorrichtungen nach der Erfindung zur Lagerung in vier Richtungen sind, ist keine gleichmäßige hin- und hergehende Bewegung des Tisches zu erwarten, da die Führungsvorrichtungen nach der Erfindung gegenüber einer vertikalen oder horizontalen Last äußerst starr sind.

Nach der Erfindung ist daher nur die lineare Führungsvorrichtung, welche als eine Basis für die Position des Tisches dient, eine Führungsvorrichtung für eine Last in vier Richtungen, um die genaue Positionierung des Tisches sicherzustellen, und die restlichen linearen Führungsvorrichtungen (oder Führungseinrichtungen) sind radiale Lastführungsvorrichtungen, welche jegliche horizontale Verlagerung des Lagerkörpers relativ zur Führungsbahn ausgleichen können. Der hin- und hergehende Tisch nach der Erfindung kann daher eine genaue und gleichmäßige hin- und hergehende Bewegung ausführen.

Weitere Einzelheiten, Merkmale und Vorteile der Erfindung ergeben sich aus der nachstehenden Beschreibung von bevorzugten Ausführungsformen unter Bezugnahme auf die beigefügte Zeichnung. Darin zeigt:

Fig. 12 eine Schnittansicht einer weiteren Ansicht einer bekannten Führungsvorrichtung zur gleichmäßigen Lagerung einer Last in vier Richtungen.

Nachstehend erfolgt eine detaillierte Beschreibung einer Führungsvorrichtung zur gleichmäßigen Lagerung einer Last in vier Richtungen und eines hin- und hergehenden Tisches nach der Erfindung unter Bezugnahme auf die beigefügte Zeichnung.

Zuerst wird auf Fig. 1 Bezug genommen, welche eine Ausführungsform einer Führungsvorrichtung nach der Erfindung für die gleichmäßige Lagerung einer Last in vier Richtungen zeigt. Die Führungsvorrichtung 10 stimmt hinsichtlich ihrer Auslegung im wesentlichen mit der bekannten Führungsvorrichtung überein, welche in JP-C-38 812/1982 angegeben ist und die voranstehend beschrieben wurde. Sie weist somit eine Führungsbahn, einen Lagerkörper 16 und eine Mehrzahl von Kugeln 22 auf, welche ermöglichen, daß der Lagerkörper 16 eine gleichmäßige hin- und hergehende Bewegung längs der Führungsbahn 12 ausführt.

Die Führungsbahn 12 hat zwei Kugelwälzflächen 14, die jeweils auf einem Paar von gegenüberliegenden Seiten hiervon ausgebildet sind. Jede Kugelwälzfläche 14 wird von einer Ausnehmung mit einem gothischen Bogen gebildet, welche zwei gekrümmte Flächen 14a und 14b umfaßt, welche miteinander verbunden sind, wie dies in Fig. 2 verdeutlicht ist. Jede der gekrümmten Flächen 14a und 14b ist im Querschnitt kreisförmig und hat einen Krümmungsradius, welcher geringfügig größer als der Radius der Kugeln 22 ist.

Der Lagerkörper 16 hat eine konkave Ausnehmung 20, welche am Boden offen ist und welche im allgemeinen komplementär zur Querschnittsgestalt der Führungsbahn 12 ausgelegt ist. Der Führungskörper 16 hat eine innere Fläche, welche von der konkaven Ausnehmung 20 gebildet wird und die insgesamt vier Kugelwälzflächen 18 umfaßt, die jeweils einer der Kugelwälzflächen 14 auf der Führungsbahn 12 zugewandt sind. Die Kugelwälzflächen 18 haben die gleiche Gestalt wie die Kugelwälzflächen 14. In anderen Worten ausgedrückt bedeutet dies, daß jede Kugelwälzfläche 18 von einer Ausnehmung mit einem gothischen Bogen gebildet wird und zwei gekrümmte Flächen 18a, 18b umfaßt, die miteinander verbunden sind, wie dies in Fig. 2 gezeigt ist. Der Lagerkörper hat auch Kugeldurchgänge 23, welche einen Umlauf der Kugeln 22 bei einer fehlenden Last von einem Ende einer der Kugelwälzflächen 18 zu dem anderen Ende derselben ermöglicht.

Die Führungsbahn 12 hat auf jeder Seite einen Vorsprung 12a, an welchem zwei der Kugelwälzflächen 14 ausgebildet sind. Andererseits hat der Lagerkörper 16 auf den jeweils beiden von der konkaven Ausnehmung 20 gegenüberliegenden Seiten eine Ausnehmung 20a, in welcher zwei der Kugelwälzflächen 18 ausgebildet sind, und in welche der Vorsprung 12a auf einer Seite der Führungsbahn 12 passend eingesetzt ist.

Eine modifizierte Ausführungsform der Führungsvorrichtung nach Fig. 1 ist in Fig. 3 gezeigt. Diese erhält man dadurch, daß die Auslegung der Vorsprünge und Ausnehmungen nach Fig. 1 umgekehrt getroffen ist. Eine Führungsbahn 13 hat ein Paar von Ausnehmungen 13a, welche jeweils auf gegenüberliegenden Seiten ausgebildet sind, und ein Lagerkörper 17 hat ein Paar von Vorsprüngen 21a, welche jeweils auf gegenüberliegenden Seiten von der konkaven Ausnehmung 21 ausgebildet sind und die jeweils in eine der Ausnehmungen 13a der Führungsbahn 13 passen.

Wiederum bezugnehmend auf Fig. 2 sind die gekrümmte Fläche 14a, welche eine Hälfte der jeweiligen Kugelwälzfläche 14 bildet, und die gekrümmte Fläche 18a, welche eine Hälfte der zugeordneten Kugelwälzfläche 18 bildet, in vertikaler Richtung zur Führungsvorrichtung 10 einander zugewandt, während die gekrümmte Fläche 14b, die die andere Hälfte der Kugelwälzfläche 14 bildet und die gekrümmte Fläche 18b, welche die andere Hälfte der Kugelwälzfläche 18 bildet, in horizontaler Richtung der Führungsvorrichtung 10 einander zugewandt sind. Somit sind die Kugeln zwischen den gekrümmten Flächen 14a und 18a in vertikaler Richtung der Führungsvorrichtung 10 und zwischen den gekrümmten Flächen 14b und 18b in horizontaler Richtung derselben gehalten.

Wenn daher eine vertikale Last auf die Führungsvorrichtung 10 einwirkt, ergibt sich somit, daß die Richtung einer Lastwirklinie L, welche durch die gekrümmten Flächen 14a und 18a geht, gleich der Richtung der Lagerung der Last auf der Führungsvorrichtung 10 ist. In ähnlicher Weise ist die Richtung einer Lastwirklinie L', welche durch die gekrümmten Flächen 14b und 18b geht wenn eine horizontale Last auf die Führungsvorrichtung 10 einwirkt, im wesentlichen gleich der Wirkrichtung der Last. Die Richtung der jeweiligen Lastwirklinien bedeutet die Richtung, in welcher die Last auf die gekrümmten Flächen wirkt.

Wenn beispielsweise eine nach unten gerichtete Last F auf die Führungsvorrichtung 10 nach Fig. 1 wirkt, wird die Last F von den gekrümmten Flächen 18a auf die Kugeln 22 übertragen, ohne daß man eine Kraftkomponente hierbei erzeugt, da die Richtung der Lastwirklinie L, welche durch die jeweilige gekrümmte Fläche 18a geht, im wesentlichen gleich der Wirkrichtung der Last ist. Die Last F wird dann von den Kugeln 22 auf die gekrümmten Flächen 14a ohne die Erzeugung einer Kraftkomponente übertragen. Da die Richtungen aller Lastwirklinien L, die durch die gekrümmten Flächen 14a und 18a gehen, im wesentlichen gleich der Wirkrichtung der Last sind, kann die Führungsvorrichtung 10 eine große, nach unten wirkende Last aufnehmen. In ähnlicher Weise kann sie eine große, in horizontaler Richtung wirkende Last f lagern, da die Richtungen aller Lastwirklinien L', welche durch die gekrümmten Flächen **14**b und **18**b gehen, im wesentlichen gleich der Wirkrichtung der Last f sind.

Die Last F führt zu keiner Verlagerung der Kontaktpunkte zwischen den Kugeln **22** und den gekrümmten Flächen **14**a und **18**a, da die Lastwirklinien L im wesentlichen gleich der Wirkrichtung der Last F ist. Auch bewirkt die Last f keine Verlagerung bei den Kontaktpunkten zwischen den Kugeln **22** und den gekrümmten Flächen **14**b und **18**b, da die Lastwirklinien L' im wesentlichen gleich der Wirkrichtung der Last f sind. Somit ist die Führungsvorrichtung **10** äußerst starr gegenüber jeglicher vertikaler oder horizontaler Last und bildet eine optimale Führungsvorrichtung als eine Basis für die Positionierung eines hin- und hergehenden Tisches.

Nunmehr sei auf **Fig.** 4 Bezug genommen, welche eine weitere Führungsvorrichtung **9** zur gleichmäßigen Lagerung einer Last in vier Richtungen zeigt, welche gemäß einer bevorzugten Ausführungsform nach der Erfindung ausgelegt ist. Diese Führungsvorrichtung umfaßt eine Führungsbahn **11**, welche hinsichtlich der Auslegungsform mit der Führungsbahn **12** übereinstimmt, die zuvor unter Bezugnahme auf **Fig.** 1 erläutert wurde. Daher kann eine nähere Beschreibung der Führungsbahn **11** entfallen. Sie umfaßt auch einen Lagerkörper **15**, welcher im wesentlichen mit dem Lagerkörper **16** übereinstimmt, der in **Fig.** 1 gezeigt ist. Der einzige Unterschied zwischen denselben ist darin zu sehen, daß die jeweilige Kugelwälzfläche **19**, welche am Lagerkörper **15** ausgebildet ist, von einer Ausnehmung mit einem einzigen Bogen gebildet wird und eine einzige gekrümmte Fläche umfaßt.

Jede Kugelwälzfläche **24**, welche auf der Führungsbahn **11** ausgebildet ist, umfaßt zwei gekrümmte Flächen **24**a und **24**b, wie dies in **Fig.** 5 gezeigt ist. Die gekrümmte Fläche **24**a weist nach oben oder unten, während die gekrümmte Fläche **24**b in horizontaler Richtung verläuft. Jede Kugelwälzfläche **19** auf dem Lagerkörper **15** ist derart ausgebildet, daß eine Lastwirklinie m, welche durch dieselbe geht, einen Winkel von etwa 45° zu den Richtungen einer vertikalen und einer horizontalen Last einschließen kann, welche auf die Führungsvorrichtung **9** wirkt. Die gekrümmten Flächen **24**a und **24**b und die Kugelwälzflächen **19** halten dazwischen Kugeln **22** in Wälzeingriff.

Die Lastwirklinien l zusammen mit einer nach unten wirkenden Last F wirken auf die gekrümmten Flächen **24**a in gleicher Richtung wie die Last F ein und in ähnlicher Weise wirken die Lastwirklinien l' zusammen mit einer horizontalen Last f auf die gekrümmten Flächen **24**b ein und stimmen im wesentlichen mit der Last f überein. Die Führungsvorrichtung **9** kann daher sowohl eine große vertikale als auch eine große horizontale Last lagern bzw. aufnehmen.

Die vertikale oder horizontale Last, welche auf die Führungsvorrichtung **9** einwirkt, wird von dem Führungskörper **15** zu den Kugeln **22** längs den Lastwirklinien m, welche durch die Kugelwälzflächen **19** gehen, übertragen und drückt hierbei die Kugeln **22** gegen die gekrümmten Flächen **24**a und **24**b, welche die Kugelwälzflächen **24** bilden, und zwar längs den Lastwirklinien l und l'. Daher tritt keine Verlagerung an den Kontaktpunkten zwischen den Kugeln **22** und den gekrümmten Flächen **24**a und **24**b auf, sondern die Führungsvorrichtung **9** hat eine hohe Steifigkeit sowohl gegenüber vertikalen als auch gegenüber horizontalen Lasten.

Es ist jedoch leicht möglich, daß, wenn die vertikale oder die horizontale Last F oder f eine gewisse Größe überschreitet, eine Verlagerung an den Kontaktpunkten zwischen den Kugeln **22** und den Kugelwälzflächen **19** bewirkt wird, da die Richtung der Lastwirklinien m nicht mit jener der Last übereinstimmen. Somit läßt sich feststellen, daß die Führungsvorrichtung **9** hinsichtlich der Steifigkeit schwächer als die in **Fig.** 1 gezeigte Führungsvorrichtung **10** ist.

Nunmehr wird auf **Fig.** 6 Bezug genommen, welche einen hin- und hergehenden Tisch (Schlitten) **1** gemäß einer Ausführungsform nach der Erfindung zeigt. Der Tisch **1** weist ein Bett **80**, einen Tisch **82** und zwei parallele, lineare Führungsvorrichtungen auf, welche mittels Schrauben **81** fest am Bett **80** angebracht sind und zur Führung bei der hin- und hergehenden Bewegung des Tisches **82** auf einer Geraden längs des Bettes **80** eingesetzt werden. Eine der linearen Führungsvorrichtungen ist eine Führungsvorrichtung **10** zur gleichmäßigen Lagerung einer Last in vier Richtungen, welche die Auslegungsform nach **Fig.** 1 aufweist und eine Basis für die Positionierung des Tisches **82** bildet. Die andere ist eine radiale Lastführungsvorrichtung **30**, welche nur eine vertikale Last aufnimmt bzw. lagert, welche auf den Tisch **82** wirkt.

Die Führungsvorrichtung **10** hat eine hohe Steifigkeit gegenüber jeglichen vertikalen oder horizontalen Lasten und ermöglicht somit die Aufrechterhaltung einer hohen Positioniergenauigkeit, wie dies voranstehend angegeben wurde. Daher wird ermöglicht, daß der hin- und hergehende Tisch **1** selbst beim Einwirken einer großen vertikalen oder horizontalen Last auf den Tisch **82** gelagert wird, ohne daß eine nennenswerte Verlagerung in Richtung der Last auftritt. Im allgemeinen ist es zutreffend, daß, wenn irgendein Unterschied hinsichtlich der Wärmedehnung zwischen einem hin- und hergehenden Tisch und einem stationären Bett vorhanden ist, oder wenn zwei lineare Führungen zur Führung des Tisches nicht in zufriedenstellender Weise parallel zueinander sind, die Lagerkörper in den linearen Führungen, welche fest mit dem Tisch verbunden sind, in horizontaler Richtung von den Führungsbahnen, welche auf dem Bett befestigt sind, verlagert werden, woraus eine starke Zunahme des Bewegungswiderstandes des Tisches durch die Führungen resultiert. Daher kann keine gleichmäßige hin- und hergehende Bewegung bei dem Tisch mehr erwartet werden.

Die radiale Lastführungsvorrichtung **30** jedoch nimmt kaum eine horizontale Last auf, sondern gleicht jede horizontale Verlagerung des Lagerkörpers **31** gegenüber der Führungsbahn **32** aus. Die Kombination aus radialer Lastführungsvorrichtung **30** mit der Führungsvorrichtung **10** für Lasten in vier Richtungen ermöglicht, daß der hin- und hergehende Tisch **1** eine gleichmäßige hin- und hergehende Bewegung ausführt, ohne daß ein nennenswerter Bewegungswiderstand vorhanden ist. Die Positionsgenauigkeit des Tisches **82** wird durch die Führungsvorrichtung **10** aufrechterhalten.

Nunmehr soll auf **Fig.** 7 Bezug genommen werden, welche in detaillierter Weise eine Ausbildungsform einer radialen Lastführungsvorrichtung zeigt. Die radiale Lastführungsvorrichtung **2** stimmt im wesentlichen hinsichtlich des Aufbaus mit der Führungsvorrichtung **10** zur gleichmäßigen Lagerung einer Last in vier Richtungen überein, welche in **Fig.** 1 gezeigt ist. Jede Kugelwälzfläche **25** auf einer Führungsbahn **3** wird von einer Nut mit einem gothischen Bogen gebildet und umfaßt zwei gekrümmte Flächen **25**a und **25**b, welche miteinander verbunden sind. Jede Kugelwälzfläche **26** an einem Lagerkörper **4** wird ebenfalls von einer Ausnehmung mit einem gothischen Bogen gebildet und umfaßt zwei gekrümmte Flächen **26**a und **26**b, wie dies in **Fig.** 8 gezeigt ist. Die Auslegung der gekrümmten Flächen **25**a, **25**b, **26**a und **26**b stimmt mit jener der gekrümmten Flächen **14**a, **14**b, **18**a und **18**b an der Führungsvorrichtung **10** überein, welche in **Fig.** 2 gezeigt ist.

Die radiale Lastführungsvorrichtung 2 unterscheidet sich von der Führungsvorrichtung **10** dahingehend, daß die gekrümmten Flächen **25**b und **26**b, welche einander zugewandt sind, einen Abstand dazwischen haben, welcher größer als jener zwischen den weiteren gekrümmten Flächen **25**a und **26**a ist, die einander zugewandt ist. Daher berühren die Kugeln **22**, welche zwischen den Kugelwälzflächen **25** auf der Führungsbahn **3** und den Kugelwälzflächen **26** auf dem Lagerkörper **4** gelagert sind, die gekrümmten Flächen **25**a und **26**a, berühren aber die gekrümmten Flächen **25**b und **26**b nicht. Diese Verhältnisse werden erreicht, da die horizontal im Abstand vorgesehenen gekrümmten Flächen **26**a an dem Lagerkörper **4** einen Abstand P_1 dazwischen haben, welcher größer als der Abstand P_2 zwischen den horizontal im Abstand angeordneten, gekrümmten Flächen **25**a auf der Führungsbahn **3** ist. Wenn der Abstand P_1 gleich P_2 wäre, würden die Kugeln **22** alle gekrümmten Flächen **25**a, **25**b, **26**a und **26**b berühren, und die Führungsvorrichtung **2** würde mit der Führungsvorrichtung **10** übereinstimmen, welche in **Fig.** 1 gezeigt ist. Die Richtung der Lastwirklinie L, welche durch das jeweilige Paar von gekrümmten Flächen **25**a und **26**a geht, welche die Kugeln **22** berühren, ist gleich der Richtung, in welcher eine vertikale Last auf die Führungsvorrichtung **2** einwirkt. Die Führungsvorrichtung **2** kann daher eine große vertikale Last lagern bzw. aufnehmen, ohne daß man eine nennenswerte Änderung hinsichtlich der Höhe hat, da keine Verlagerung zu den Kontaktpunkten zwischen den Kugeln **22** und den gekrümmten Flächen **25**a und **26**a auftritt.

Wenn eine horizontale Last auf die Führungsvorrichtung **2** wirkt, gestatten die Zwischenräume zwischen den Kugeln **22** und den gekrümmten Flächen **25**b und **26**b eine geringfügige horizontale Verlagerung des Lagerkörpers **4** gegenüber der Führungsbahn **3**. Diese Verlagerung behindert die gleichmäßige Wirkung der Führungsvorrichtung **2** nicht.

Fig. 9 zeigt eine weitere Ausführungsform einer radialen Lastführungsvorrichtung. Die radiale Lastführungsvorrichtung **5** weist eine Führungsbahn **6** auf, welche insgesamt vier Kugelwälzflächen **27** hat, ferner einen Lagerkörper **7** auf, welcher insgesamt vier Kugelwälzflächen **28** hat, welche jeweils einer der Kugelwälzflächen **27** auf der Führungsbahn **6** zugewandt ist, und eine Mehrzahl von Kugeln **22** auf, welche in Wälzeingriff zwischen den Kugelwälzflächen **27** und **28** gehalten sind, wie dies bei der Führungsvorrichtung **2** der Fall ist, welche in **Fig.** 7 gezeigt ist.

Jede Kugelwälzfläche **27** und **28** wird jedoch von einer Ausnehmung mit einem einzigen Boden gebildet und umfaßt eine einzige gekrümmte Fläche, wie dies in **Fig.** 10 gezeigt ist. Die Richtung der Lastwirklinie L, welche durch das jeweilige Paar von Kugelwälzflächen **27** und **28** geht, stimmt mit der Richtung überein, in welcher eine vertikale Last auf die Führungsvorrichtung **5** einwirkt. Die Führungsvorrichtung **5** kann daher eine große vertikale Last lagern bzw. aufnehmen, ohne daß eine nennenswerte Höhenänderung vorhanden ist.

Die Führungsvorrichtung **5** hat keine Kugelwälzfläche, welche die horizontale Bewegung der Kugeln **22** einschränkt.

Wenn daher eine horizontale Last auf die Führungsvorrichtung **5** einwirkt, wird eine Verlagerung der Kontaktpunkte zwischen den Kugeln **22** und den Kugelwälzflächen **27** und **28** bewirkt, und hierdurch eine horizontale Verlagerung des Lagerkörpers **7** gegenüber der Führungsbahn **6**. Diese Verlagerung behindert die gleichmäßige Bewegung der Führungsvorrichtung **5** nicht.

Patentansprüche

1. Führungsvorrichtung zur Lagerung einer Last in vier Richtungen, mit einer Führungsbahn (**12**), welche eine Mehrzahl von Kugelwälzflächen (**14**) hat, die auf ihrer Außenfläche ausgebildet sind, einem Lagerkörper (**16**), welcher eine konkave Ausnehmung (**20**) hat, in welche die Führungsbahn (**12**) paßt, wobei der Lagerkörper (**16**) eine Mehrzahl von Kugelwälzflächen (**14**) hat, welche auf seiner inneren Fläche ausgebildet sind und die jeweils einer der Kugelwälzflächen (**14**) auf der Führungsbahn (**12**) zugewandt sind, und mit einer Mehrzahl von Kugeln (**22**), welche zwischen den Kugelwälzflächen (**14**) auf der Führungsbahn (**12**) und den Kugelwälzflächen (**14, 18**) auf dem Lagerkörper (**16**) gehalten sind, welche den Kugelwälzflächen (**14**) auf der Führungsbahn (**12**) zugewandt sind, **dadurch gekennzeichnet,** daß die jeweiligen Kugelwälzflächen (**14, 18**) auf wenigstens der Führungsbahn (**12**) oder des Lagerkörpers (**16**) von einer Ausnehmung gebildet werden, welche in Form eines gothischen Bogens im Querschnitt ausgestaltet ist, und zwei gekrümmte Flächen (**14a, 14b; 18a, 18b**) umfaßt, welche miteinander verbunden sind, und daß die gekrümmten Flächen (**14a, 14b; 18a, 18b**) derart angeordnet sind, daß eine vertikale oder horizontale Last, welche auf die Führungsvorrichtung (**10**) einwirkt, auf die eine oder die andere gekrümmte Fläche (**14a, 14b; 18a, 18b**) im wesentlichen in die Richtung wirken kann, in welche die Last auf die Führungsvorrichtung (**10**) einwirkt.
2. Führungsvorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß die jeweiligen Kugelwälzflächen (**14, 18**) sowohl auf der Führungsbahn (**12**) als auch auf dem Lagerkörper (**16**) von dieser Ausnehmung gebildet werden.
3. Führungsvorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß die Kugelwälzflächen (**14a, 14b**) auf der Führungsbahn (**12**) von dieser Nut gebildet werden, während die jeweiligen Kugelwälzflächen (**19**) auf dem Lagerkörper (**15**) von einer Ausnehmung gebildet werden, die in Form eines einzigen Bogens im Querschnitt ausgelegt ist und eine einzige gekrümmte Fläche umfaßt, welche derart angeordnet ist, daß die vertikale oder horizontale Last, welche auf die Führungsvorrichtung (**9**) einwirkt, auf die einzige gekrümmte Fläche unter einem Winkel von etwa 45° zu jener Richtung wirken kann, in welcher die Last auf die Führungsvorrichtung (**9**) einwirkt (**Fig.** 4 und 5).
4. Hin- und hergehender Tisch, welcher ein stationäres Bett (**80**), eine Mehrzahl von im wesentlichen parallelen, linearen Führungsvorrichtungen, die an dem Bett (**80**) angebracht sind und einen hin- und hergehenden Tisch (**1**) aufweist, welcher auf einer

geraden Linie längs des Bettes (**80**) durch die linearen Führungsvorrichtungen hin- und hergehend bewegbar ist, wobei jede Führungsvorrichtung eine Führungsbahn (**12**) aufweist, welche fest mit dem Bett (**80**) verbunden ist, und eine Mehrzahl von Kugelwälzflächen (**14**) hat, welche auf der äußeren Fläche ausgebildet sind, einen Lagerkörper (**16**) aufweist, welcher fest mit dem Tisch (**82**) verbunden ist, und eine Ausnehmung hat, in welche die Führungsbahn (**12**) paßt, wobei der Lagerkörper (**16**) eine Mehrzahl von Kugelwälzflächen (**18**) hat, welche auf der inneren Fläche ausgebildet sind und jeweils einer der Kugelwälzflächen (**14**) auf der Führungsbahn (**12**) zugewandt sind, und eine Mehrzahl von Kugeln (**22**) aufweist, welche zwischen den Kugelwälzflächen (**14**) auf der Führungsbahn (**12**) und den Kugelwälzflächen (**18**) auf dem Lagerkörper (**16**) gehalten sind, welche den Kugelwälzflächen (**14**) auf der Führungsbahn (**12**) zugewandt sind, dadurch gekennzeichnet, daß eine der linearen Führungsvorrichtungen eine Führungsvorrichtung (**10**) zur Lagerung einer Last in vier Richtungen ist, bei der die jeweiligen Kugelwälzflächen (**14**a, **14**b) wenigstens der Führungsbahn (**12**) oder des Lagerkörpers (**16**) von einer Ausnehmung gebildet werden, die in Form eines gothischen Bogens im Querschnitt ausgestaltet ist, und zwei gekrümmte Flächen (**14**a, **14**b; **18**a, **18**b) umfaßt, welche miteinander verbunden sind, und daß die gekrümmten Flächen (**14**a, **14**b; **18**a, **18**b) derart angeordnet sind, daß eine vertikale oder eine horizontale Last,· welche auf die lineare Führungsvorrichtung (**10**) wirkt, auf die eine oder die andere gekrümmte Fläche (**14**a, **14**b,; **18**a, **18**b) im wesentlichen in jener Richtung einwirken kann, in der die Last auf diese eine lineare Führungsvorrichtung (**10**) einwirkt, während die restlichen linearen Führungsvorrichtungen von einer Führungsvorrichtung (**30**) für eine radiale Last gebildet werden, welche lediglich eine vertikale Last aufnimmt. (**Fig.** 6 und 7).

5. Vorrichtung nach Anspruch 4, dadurch gekennzeichnet, daß die jeweiligen Kugelwälzflächen (**14**, **18**) sowohl auf der Führungsbahn (**12**) als auch auf dem Lagerkörper (**16**) bei einer linearen Führungsvorrichtung (**10**) von dieser Ausnehmung gebildet werden.

6. Vorrichtung nach Anspruch 4, dadurch gekennzeichnet, daß die jeweiligen Kugelwälzflächen (**14**, **18**) auf der Führungsbahn (**12**) bei dieser einen linearen Führungsvorrichtung (**10**) von dieser Ausnehmung gebildet werden, während die jeweiligen Kugelwälzflächen auf dem Lagerkörper (**16**) bei dieser einen linearen Führungsvorrichtung (**10**) von einer Ausnehmung gebildet wird, die in Form eines einzigen Bogens im Querschnitt ausgelegt ist und eine einzige gekrümmte Fläche aufweist, welche derart angeordnet ist, daß die vertikale oder horizontale Last auf die einzige gekrümmte Fläche unter einem Winkel von etwa 45° zu jener Richtung einwirken kann, in welcher die Last auf diese eine lineare Führungsvorrichtung (**10**) einwirkt.

7. Vorrichtung nach Anspruch 5 oder 6, dadurch gekennzeichnet, daß die jeweiligen Kugelwälzflächen (**14**, **18**) sowohl auf der Führungsbahn (**12**) als auch auf den Lagerkörper (**16**) bei dieser Führungsvorrichtung (**10**) für radiale Belastungen von einer Ausnehmung gebildet werden, welche in Form eines gothischen Bogens im Querschnitt ausgelegt ist und zwei gekrümmte Flächen (**14**a, **14**b; **18**a, **18**b) umfaßt, welche miteinander verbunden sind, und die derart angeordnet sind, daß eine vertikale oder horizontale Last, welche auf die Führungsvorrichtung zur Lagerung einer radialen Last einwirkt, auf die eine oder die andere letztgenannte gekrümmte Fläche (**14**a, **14**b; **18**a, **18**b) im wesentlichen in jene Richtung einwirken kann, in welcher die Last auf die Führungsvorrichtung (**10**) zur Lagerung der radialen Last einwirkt, wobei eine der gekrümmten Flächen auf der Führungsbahn (**12**) und eine der gekrümmten Flächen (**18**) auf dem Lagerkörper (**16**) einander zugewandt sind und vertikal im Abstand voneinander angeordnet sind, während die andere der gekrümmten Flächen auf der Führungsbahn (**12**) und die andere der gekrümmten Flächen auf dem Lagerkörper (**16**) einander zugewandt sind und horizontal in einem Abstand voneinander derart vorgesehen sind, daß dieser Abstand größer als der Abstand ist, um den die vertikal im Abstand angeordneten gekrümmten Flächen voneinander beabstandet sind, so daß die Kugeln (**22**) nur die vertikal im Abstand angeordneten gekrümmten Flächen berühren können. (**Fig.** 7 und 8).

8. Vorrichtung nach Anspruch 5 oder 6, dadurch gekennzeichnet, daß die jeweiligen Kugelwälzflächen (**27**, **28**) sowohl auf der Führungsbahn (**6**) als auch auf dem Lagerkörper (**7**) bei der Führungsvorrichtung (**5**) zur Lagerung einer radialen Last von einer Ausnehmung gebildet werden, welche im Querschnitt einen einzigen Bogen hat und eine einzige gekrümmte Fläche aufweist, welche derart angeordnet ist, daß eine vertikale Last, welche auf die Führungsvorrichtung (**5**) zur Lagerung einer radialen Last einwirkt, auf die einzige gekrümmte Fläche im wesentlichen in die Richtung wirken kann, in die die Last auf die Führungsvorrichtung (**5**) zur Lagerung einer radialen Last einwirkt. (**Fig.** 9 und 10).

(54) Mit Flansch versehenes, lineares Kugellager

(57) Es wird ein mit einem Flansch versehenes, lineares Kugellager angegeben, bei dem ein Kugelkäfig zur Anordnung von Kugeln zwischen einem Lagergehäuse und einer Lagerwelle vorgesehen ist, welcher mit einem Flansch zum Festlegen an einem Befestigungsteil, wie einem Bett oder einem Tisch, versehen ist. Somit kann dem Lagergehäuse eine zylindrische Gestalt verliehen werden, welche keinen Flansch hat, so daß eine einfache Bearbeitung möglich ist, um die Herstellungskosten zu senken und die Produktivität beträchtlich zu steigern.

DE 42 10 655 A 1

Beschreibung

Die Erfindung bezieht sich auf ein lineares Kugellager, wie ein Kugel-Loslager oder eine Kugel-Keilverbindung, welche bei linearen Führungsteilen bei unterschiedlichen Industriemaschinen eingesetzt werden, und insbesondere befaßt sich die Erfindung mit einer Weiterentwicklung eines linearen Kugellagers mit einer Bauart, die einen Flansch zum Fixieren des Lagers hat.

Das lineare Kugellager sowie das Kugel-Loslager oder eine Kugel-Keilverbindung wird in großem Umfang bei linearen Führungsteilen von unterschiedlichen Industriemaschinen eingesetzt, so daß es unterschiedliche Erzeugnisse gibt, welche an eine Vielzahl von unterschiedlichen Einsatzarten angepaßt sind.

Fig. 10 zeigt eine bevorzugte Ausführungsform eines sogenannten "mit Flansch versehenem Kugel-Loslager", welches einen Flansch zum Fixieren des Lagers an einem Befestigungsteil, wie einem Bett oder einem Tisch, hat.

Insbesondere ist das mit Flansch versehene Kugel-Loslager so ausgelegt, daß es folgendes umfaßt: ein Lagergehäuse **101**, welches derart ausgebildet ist, daß es ein im wesentlichen zylindrisches Teil hat und an welchem integral ein Flansch **103** ausgeformt ist, welcher Befestigungsschrauböffnungen **102** am Außenumfang derart hat, daß er sich linear um eine Lagerwelle bzw. Lagerachse **105** über eine Mehrzahl von endlos umlaufenden Kugeln **104** bewegen kann; und einen Kugelkäfig **107**, welcher mit Kugelführungsnuten **106** ausgebildet ist, um die Kugeln **104** endlos zwischen der Lagerwelle **105** und dem Lagergehäuse **101** umlaufen zu lassen, und welches fest passend in einem hohlen Teil des Lagergehäuses **101** vorgesehen ist. Somit wird dieses Kugel-Loslager so eingesetzt, daß der Flansch **103** an einem Befestigungsteil **109** beispielsweise mit Hilfe von Befestigungsschrauben **108** angebracht wird, und daß das Befestigungsteil **109** und die Lagerwelle **105** relativ zueinander eine Gleitbewegung ausführen können.

Bei dem linearen Kugellager dieser Bauart ist es erforderlich, daß das Lagergehäuse mittels einer Härtungsbehandlung behandelt wird, so daß die Verschleißfestigkeit des inneren Umfangs des Lagergehäuses verbessert wird, auf welchem die Kugeln bei der Ausführung einer Abwälzbewegung geführt sind. Diese Härtungsbehandlung jedoch bringt große Schwierigkeiten bei der Herstellung des vorstehend angegebenen, mit einem Flansch versehenen Kugel-Loslagers mit sich. Der Grund hierfür wird nachstehend näher beschrieben. Da der Flansch dicker als die anderen Teile des Lagergehäuses ausgelegt sind, bleibt ein Wärmeverzug im Lagergehäuse erhalten, wenn der Flansch gehärtet wurde und nachdem er abgeschliffen wurde, so daß das Lagergehäuse nicht genau fertiggestellt werden kann. Wenn hingegen der auszubildende Flansch nach der Härtungsbehandlung erstellt wird, ist das Material zu hart, um geschliffen zu werden.

Andererseits bringt der Flansch am Lagergehäuse eine gewisse Schwierigkeit dahingehend mit sich, daß das Schleifen wesentlich umständlicher als beim Schleifen eines gerad-zylindrischen Gehäuseteils wird, welches keinen Flansch hat. Ein derartiges gerad-zylindriges Lagergehäuse läßt sich effektiv in einem Schritt unter Verwendung einer spitzenlosen Rundschleifmaschine abschleifen, aber ein mit Flansch versehenes Lagergehäuse kann nicht mittels einer spitzenlosen Rundschleifmaschine bearbeitet werden, so daß es auf eine zyklische Weise durch Schleifen bearbeitet werden muß. Insbesondere macht ein solches Schleiferverfahren zwei Stufen erforderlich, d. h. die Stufen zum Schleifen des zylindrischen Teils und des Flansches.

Daher wurde zur Überwindung dieser Schwierigkeit ein lineares Kugellager vorgeschlagen, welches dadurch hergestellt ist, daß ein im allgemeinen ringförmiges Flanschteil und ein Lagergehäuse gesondert voneinander ausgeformt bzw. gegossen sind und daß der Flansch und das Lagergehäuse mittels Preßsitz oder Hartlöten nach der Härtungsbehandlung des Lagergehäuses verbunden werden. Hierdurch ergibt sich jedoch eine weitere Schwierigkeit hinsichtlich der Anzahl von Bearbeitungsschritten zum Herstellungszeitpunkt oder der Anzahl der Teile, und daher ist eine derartige Lösung im Hinblick auf die Herstellungskosten und die Herstellungseffizienz nicht zufriedenstellend.

Die Erfindung zielt daher darauf ab, unter Überwindung der zuvor geschilderten Schwierigkeiten ein mit einem Flansch versehenes lineares Kugellager bereitzustellen, bei welchem sich die Herstellungskosten senken lassen und sich die Herstellungsleistung beträchtlich verbessern läßt.

Um die vorstehend angegebene Zielsetzung zu erreichen, wird nach der Erfindung ein mit einem Flansch versehenes, lineares Kugellager bereitgestellt, welches folgendes aufweist: ein Lagergehäuse, welches einen hohlen Teil darin hat und mittels eines Lagerschaftes oder einer Lagerwelle zur Ausführung von linearen Bewegungen geführt ist; eine Mehrzahl von Kugeln, welche zwischen dem Lagergehäuse und der Lagerwelle zur Ausführung einer Abwälzbewegung unter einer Belastung gehalten sind; und einen Kugelkäfig, welcher passend in dem hohlen Teil des Lagergehäuses angeordnet und die Kugeln in ihrer Anordnung hält, wobei sich die Weiterentwicklung dadurch auszeichnet, daß ein Flansch von dem Kugelkäfig zum Fixieren des Lagers an einem Befestigungsteil, wie einem Bett oder einem Tisch, vorsteht.

Bei dieser technischen Auslegung kann der Flansch, der von dem vorstehend genannten Kugelkäfig vorstehen muß, dadurch gebildet werden, daß ein ringförmiges Flanschteil an den äußeren Umfang des Kugelkäfigs geschweißt wird. Vorzugsweise sind jedoch der Flansch und der Kugelkäfig integral mittels Spritzgießen oder Verspritzens eines Kunstharzes einteilig ausgebildet.

Ferner läßt sich das Kugellager, bei welchem derartige technische Einrichtungen vorgesehen sind, dadurch beispielhaft näher beschreiben, daß eine Mehrzahl von endlos umlaufenden Kugeln zwischen einem zylindrischen Lagergehäuse und einer Lagerwelle derart gehalten sind, daß sie relative Linearbewegungen aufnehmen. Die technische Einrichtung kann nicht nur bei Kugel-Loslager der üblichen Bauart, sondern auch bei Kugel-Keilverbindungen eingesetzt werden, welche die Fähigkeit haben, eine Drehmomentübertragung zwischen dem Lagergehäuse und der Lagerwelle zu ermöglichen.

Da der Flansch am Kugelkäfig ausgebildet ist, um dem Lagergehäuse eine gerad-zylindrische Gestalt entsprechend den vorstehend angegebenen technischen Einzelheiten zu verleihen, kann die Härtungsbehandlung des Lagergehäuses beträchtlich vereinfacht werden und insbesondere wird auch das Schleifen mittels einer spitzenlosen Rundschleifmaschine ermöglicht. Als Folge hiervon läßt sich die Schleifbehandlung auf effektive Weise mit vertretbaren Kosten vornehmen, wodurch sich die Ausstoßleistung verbessern läßt und sich die Herstellungskosten drastisch senken lassen.

Wenn man ferner den Flansch von dem Lagergehäuse wegläßt, läßt sich das Lagergehäuse des linearen Kugellagers ohne Flansch leicht in ein solches für ein mit einem Flansch versehenes lineares Kugellager umwandeln, so daß die Teile für unterschiedliche Produkte gemeinsam genutzt werden können. Auch hierdurch wird es möglich, die Herstellungseffizienz zu verbessern und die Herstellungskosten zu senken.

Wenn ferner der Flansch und der Kugelkäfig einteilig mittels Spritzgießen aus einem Kunstharz hergestellt sind, kann eine weitere Verbesserung hinsichtlich der Herstellungseffizienz erwartet werden, da ein zusätzlicher Schritt bei der Herstellung des Flansches erforderlich wird.

Weitere Einzelheiten, Merkmale und Vorteile der Erfindung ergeben sich aus der nachstehenden Beschreibung von bevorzugten Ausführungsformen unter Bezugnahme auf die beigefügte zeichnung. Darin zeigt:

Fig. 10 eine Seitenansicht zur Verdeutlichung eines mit einem Flansch versehenen, linearen Kugellagers üblicher Bauform.

Ein mit einem Flansch versehenes, lineares Kugellager nach der Erfindung wird nachstehend unter Bezugnahme auf die Zeichnungen näher erläutert.

Fig. 1 ist eine Seitenansicht zur Verdeutlichung einer ersten bevorzugten Ausführungsform eines mit einem Flansch versehenen Kugel-Loslagers nach der Erfindung. Das mit einem Flansch versehene Kugel-Loslager gemäß dieser bevorzugten Ausführungsform umfaßt hinsichtlich der Konstruktion folgendes: ein Lagergehäuse **2**, das mittels einer Lagerwelle bzw. einer Lagerachse **1** zur Ausführung von linearen Bewegungen geführt ist; eine Mehrzahl von Kugeln **3**, welche eine Abwälzbewegung ausführen, wenn das Lager eine Belastung zwischen der Lagerwelle **1** und dem Lagergehäuse **2** aufnimmt, und einen Kugelkäfig **5**, welcher eine äußere Umfangsfläche hat, welche mit einem vorspringenden Flansch **4** versehen ist und passend in einem hohlen Teil **21** des Lagergehäuses **2** zum Halten und Anordnen der Kugeln **3** vorgesehen ist.

Vor allem ist das Lagergehäuse **2** derart ausgebildet, daß es eine im allgemeinen zylindrische Gestalt derart hat, daß es lose mit einem vorbestimmten Zwischenraum um die Lagerwelle **1** passend angeordnet ist, und daß der Innenumfang wie in **Fig.** 5 gezeigt mit fünf lasttragenden Wälzflächen **22** versehen ist, die in regelmäßigen Umfangsabständen zum Halten der Kugeln **3** mit der Lagerwelle **1** und den nichtlasttragenden Wälznuten **23** angeordnet sind, welche jeweils zwischen zwei benachbarten, lasttragenden Wälzflächen **22** zur Ausführung einer Abwälzbewegung der Kugeln angeordnet sind, welche von der Lastaufnahme freikommen. Ferner ist das hohle Teil **21** an einem Öffnungsrand mit einer ringförmigen Nut **24** versehen, welche in Umfangsrichtung zur Aufnahme einer später noch zu beschreibenden, achteckigen Klammer **6** verläuft.

Andererseits ist der Kugelkäfig **5** in den **Fig.** 3 und 4 gezeigt derart ausgebildet, daß er eine im allgemeinen zylindrische Gestalt und eine Durchgangsöffnung **51** hat, um in passender Weise die Lagerwelle **1** darin aufzunehmen und die eine äußere Umfangsfläche hat, welche mit einem Flansch **4** versehen ist, welcher seinerseits mit Schraubkopföffnungen **41** versehen ist. Der Kugelkäfig **5** ist einteilig mit einem Flansch **4** mittels Spritzgießen eines Kunstharzes ausgebildet. Der Kugelkäfig **5** hat an seinem äußeren Umfang eine derartige Ausbildung, daß sie den einzelnen, lasttragenden Wälzflächen **22** entspricht, wozu folgendes vorgesehen ist: mit Schlitzen versehene, lasttragende Kugelführungsnuten **52**, welche verhindern, daß die Kugeln **3** auf den vorstehend angegebenen, lasttragenden Wälzflächen **22** eine Abwälzbewegung ausführen und aus den Nuten heraustreten, wenn das Lagergehäuse **2** von der Lagerwelle **1** abgezogen wird; nichtlasttragende Kugelführungsnuten **53** zum Anordnen der entlasteten Kugeln, welche eine Abwälzbewegung in den nichtlasttragenden Wälznuten **23** ausführen; und Kugelwendenuten **54** zur Herstellung von Verbindungen und Verbindungseinrichtungen zwischen den lasttragenden Kugelführungsnuten **52** und den nichtlasttragenden Kugelführungsnuten **53**, um die Kugeln **3** endlos zwischen den beiden Nuten **52** und **53** umlaufen zu lassen. Andererseits ist der äußere Umfang des Kugelkäfigs **5** mit einer ringförmigen Nut **55** versehen, welche der ringförmigen Nut **24** des vorstehend angegebenen Lagergehäuses **2** zugeordnet ist. Somit ist ein Raum zwischen der ringförmigen Nut **24** des Lagergehäuses **2** und der ringförmigen Nut **55** des Kugelkäfigs **5** ausgebildet, welche einander gegenüberliegen, wenn der Kugelkäfig **5** passend auf dem Lagergehäuse **2** vorgesehen ist.

Bei der vorliegenden bevorzugten Ausführungsform sind das Lagergehäuse **2** und der Kugelkäfig **5** mit Hilfe einer achteckförmigen Klammer **6** verbunden, wie dies in den **Fig.** 6 und 7 gezeigt ist. Eine spezielle Kupplungsverbindung wird nachstehend näher beschrieben. Zuerst wird die achteckige Klammer **6** passend in die ringförmige Nut **24** eingesetzt, welche in dem inneren Umfang des Lagergehäuses **2** ausgebildet ist und dann wird der Kugelkäfig **5** mittels Preßsitz in das hohle Teil **21** des Lagergehäuses **2** eingesetzt. Dann kommt das Endteil des Kugelkäfigs **5** in Anlageberührung gegen die einzelnen, mittleren Seitenteile **61** der achteckigen Klammer **6**, so daß diese Klammer **6** elastisch verformt oder gedehnt wird. Wenn die Preßpassungsverbindung für den Kugelkäfig **5** fortgesetzt wird, kommt die ringförmige Nut **55** zur Ausrichtung mit der ringförmigen Nut **24** des Lagergehäuses **2**. Dann hat die achteckige Klammer **6** mittlere Seitenteile **61**, welche stufenförmig in die ringförmige Nut **55** des Kugelkäfigs **5** gehen, bis ihre Ecken **62** in die ringförmige Nut **24** passen, während die mittleren Seitenteile **61** in die ringförmige Nut **55** passen. Somit sind das Lagergehäuse **2** und der Kugelkäfig **5** miteinander gekoppelt bzw. verbunden.

Wenn darüber hinaus das mit einem Flansch versehene Kugel-Loslager mit dem vorstehend genannten Aufbau und gemäß der bevorzugten Ausführungsform nach der Erfindung zusammengesetzt ist, hat der Flansch **4** des Kugelkäfigs **5**, welcher an einem (nicht gezeigten) Teil mit Hilfe von (nicht gezeigten) Schrauben angebracht ist, eine solche Auslegung, daß man relativ lineare Bewegungen zwischen dem Flanschbefestigungsteil und der Lagerwelle **1** erhält, wie dies auch bei dem mit einem Flansch versehenen Kugel-Loslager üblicher Bauart der Fall ist.

Dank des Flansches **4**, welcher von dem Kugelkäfig **5** bei der bevorzugten Ausführungsform nach der Erfindung vorsteht, lassen sich jedoch zeitraubende Arbeitsschritte, die bei der Ausbildung des Flansches **4** an dem Lagergehäuse **2** bei der üblichen Ausführungsform erforderlich sind, vermeiden, um das maschinelle Bearbeiten des Lagergehäuses **2** beträchtlich zu vereinfachen und hierdurch die Herstellungsleistung zu verbessern und die Herstellungskosten zu senken.

Insbesondere ist bei der bevorzugten Ausführungsform nach der Erfindung der Flansch **4** integral mit dem Kugelkäfig **5** mittels Spritzgießen aus einem Kunstharz derart ausgebildet, daß der Schritt zum Ausbilden des Flansches **4** nicht vorsätzlich vorgesehen zu sein braucht, wodurch man die Produktivität weiter steigern kann.

Fig. 9 zeigt eine zweite bevorzugte Ausführungsform eines mit einem Flansch versehenen Kugel-Loslagers nach der Erfindung.

Der Flansch **4** und der Kugelkäfig **5** sind einteilig bei dieser bevorzugten Ausführungsform ebenfalls ausgeformt, aber das Verfahren zum Verbinden von Kugelkäfig **5** und Lagergehäuse **2** unterscheidet sich von jenem nach der ersten bevorzugten Ausführungsform. Nach dem passenden Einsetzen des Kugelkäfigs **5** in das Lagergehäuse **2** wird insbesondere gemäß dieser bevorzugten Ausführungsform ein Anschlagring **7** passend auf die äußere Umfangsfläche des Endabschnitts des Kugelkäfigs **5** gesetzt, welcher von dem Lagergehäuse **2** vorsteht, und der Anschlagring **7** und das Lagergehäuse **2** werden so in Eingriff gebracht, daß der Kugelkäfig **5** und das Lagergehäuse **2** miteinander verbunden sind. Ansonsten stimmt die restliche Auslegung mit jener bei der voranstehend beschriebenen bevorzugten Ausführungsform überein und die Beschreibung kann daher entfallen, da insbesondere für gleiche oder ähnliche Teile die gleichen Bezugszeichen verwendet werden.

Bei diesem mit einem Flansch versehenen Kugel-Loslager ist der Flansch **4** ebenfalls integral mit dem Kugelkäfig **5** ausgebildet, wodurch ermöglicht wird, daß sich die Herstellungsleistung verbessern läßt und sich die Herstellungskosten senken lassen.

Patentansprüche

1. Mit einem Flansch versehenes, lineares Kugellager, welches aufweist: ein Lagergehäuse **(2)**, welches ein hohles Teil **(21)** darin hat und mittels einer Lagerwelle **(1)** zur Ausführung von linearen Bewegungen geführt ist, eine Mehrzahl von Kugeln **(8)**, welche zwischen dem Lagergehäuse **(2)** und der Lagerwelle **(1)** zur Ausführung einer Abwälzbewegung unter einer Belastung gehalten sind, und einen Kugelkäfig **(5)**, welcher passend in das hohle Teil **(21)** des Lagergehäuses **(2)** zum Halten und Anordnen der Kugeln **(3)** eingesetzt ist, **dadurch gekennzeichnet,** daß ein Flansch **(4)** von dem Kugelkäfig **(5)** zum Fixieren des Lagers an einem Befestigungsteil, wie einem Bett oder einem Tisch, vorsteht.

2. Mit einem Flansch versehenes, lineares Kugellager nach Anspruch 1, dadurch gekennzeichnet, daß der Flansch **(4)** einteilig mit dem Kugelkäfig **(5)** mittels Spritzgießen eines Kunstharzes ausgebildet ist.

3. Mit einem Flansch versehenes, lineares Kugellager, gekennzeichnet durch: ein Lagergehäuse **(2)**, welches ein hohles Teil **(21)** darin hat und mittels einer Lagerwelle **(1)** zur Ausführung von linearen Bewegungen geführt ist, eine Mehrzahl von Kugeln **(3)**, welche zwischen dem Lagergehäuse **(2)** und der Lagerwelle **(1)** zur Ausführung einer Abwälzbewegung und einer Belastung gehalten sind, einen Kugelkäfig **(5)**, welcher einen Flansch hat, der von dem äußeren Umfang desselben zum Fixieren des Lagers an einem Befestigungsteil, wie einem Bett oder einem Tisch, vorsteht und passend in das hohle Teil **(21)** des Lagergehäuses **(2)** zum Halten und Anordnen der Kugeln **(3)** eingesetzt ist, und eine vieleckige Klammer **(6)**, welche Ecken hat, welche in eine ringförmige Nut **(24)** passen, die in dem inneren Umfang des Lagergehäuses **(2)** ausgebildet sind, und die Mittelteile an den Seiten hat, welche mit den Ecken verbunden sind, welche in eine ringförmige Nut **(54)** passen, welche in dem äußeren Umfang des Kugelkäfigs **(5)** ausgebildet ist, um das Lagergehäuse **(2)** und den Kugelkäfig **(5)** fest zu verbinden.

(54) Kugelumlaufspindel-Führungseinheit und Fördertisch mit Verwendung desselben

(57) Da bei der Kugelumlaufspindel-Führungseinheit nach der Erfindung eine Führungsschiene von einem U-Materialteil mit einer Ausnehmung gebildet wird, und eine Kugelumlaufspindelwelle mit einem beweglichen Teil zusammenarbeitet, welches hin- und hergehend beweglich in der Ausnehmung längs einer Längsrichtung der Führungsschiene derart ist, daß der Flächenschwerpunkt der Führungsschiene in der Nähe der Achse der Kugelumlaufspindelwelle liegt. Wenn daher eine Vorspannung auf die Kugelumlaufspindelwelle aufgebracht wird, wird eine Geradlinigkeit der Führungsschiene hierdurch nicht beeinträchtigt, und eine Vorschubgenauigkeit des beweglichen Teils läßt sich aufrecht erhalten. Ferner kann die Führungsschiene an ihren unteren Flächen und Seitenflächen mit Bezugsebenen versehen sein, welche zur Einstellung der Parallelität zwischen der Führungsschiene und der Achse der Kugelumlaufspindelwelle genutzt werden, wobei sich die Montage und die Einstellung des Tisches vereinfachen lassen.

DE 41 35 167 A1

Beschreibung

Die Erfindung bezieht sich allgemein auf eine Kugelumlaufspindel-Führungseinheit bei Anwendung in einem linear beweglichen Teil, beispielsweise einer Werkzeugmaschine und eines Roboters, und sie bezieht sich auch auf einen Fördertisch unter Einsatz einer solchen Einheit.

Eine Fördereinrichtung unter Einsatz einer Kugelumlaufspindel hat Auslegungsformen, die beispielsweise in **Fig.** 24 gezeigt sind (siehe offengelegte japanische Patentanmeldung No. 62-2 00 016 und weitere). In dieser Figur ist ein bewegliches Teil **11** mittels eines Paars von Führungsschienen **101** gelagert und in eine Längsrichtung hiervon beweglich. Eine Kugelumlaufspindelwelle **102** ist in Gewindeeingriff in dem beweglichen Teil **100**, um das bewegliche Teil **100** bei der Drehung der Welle **102** hin- und hergehend zu bewegen. Das bewegliche Teil **100** ist an gegenüberliegenden Seiten mittels Führungsschienen **101** unter Zwischenlage von Kugeln **103** gelagert. Durch die direkte Einschraubbewegung der Kugelumlaufspindelwelle **102** in das bewegliche Teil **100** wird eine kompakte Auslegung der Vorrichtung erreicht. Bei einer üblichen Auslegungsform, bei welcher eine Kugelumlaufspindel zum Antreiben eines Tisches auf allgemeine Weise eingesetzt wird, kann eine Vorspannung auf die Kugelumlaufspindelwelle aufgebracht werden, um Genauigkeitsabweichungen verursacht durch eine Wärmedehnung auszugleichen. Bei der in **Fig.** 24 gezeigten Vorrichtung bewirkt die auf die Kugelumlaufspindel **102** aufgebrachte Vorspannung ein Biegemoment, welches auf die Führungsschienen **101** einwirkt, wodurch ein Verziehen der Führungsschienen **101** bewirkt werden kann und somit ein Bett und/oder ein Tisch, an welchem die Führungsschienen **101** angebracht sind, sich biegen können, wodurch man eine Herabsetzung einer Vorschubgenauigkeit des beweglichen Teiles erhält.

Da das bewegliche Teil **100**, mit dem die Kugelumlaufspindelwelle **102** über eine Gewindeverbindung verbunden ist, von den Führungsschienen **101** getragen wird, dient das bewegliche Teil **100** dazu, eine Beschleunigung der Kugelumlaufspindelwelle **102** zu verhindern. Wenn jedoch die Vorspannung aufgebracht ist, wird die Kugelumlaufspindelwelle **102** ebenfalls durch eine Reaktionskraft gebogen, welche durch die gebogenen Führungsschienen **101** einwirkt, und somit kann man bei der Kugelumlaufspindelwelle **102** nicht eine vorbestimmte Geradlinigkeit einhalten, so daß sich Verzerrungen ergeben.

Um diese durch die Vorspannung verursachten Schwierigkeiten zu vermeiden, können die Abmessungen der Führungsschienen **101** vergrößert werden, um eine höhere Steifigkeit bei dem Stand der Technik zu erzielen. Hierdurch nehmen jedoch die Gesamtabmessungen der Vorrichtung und das Gewicht der Vorrichtung sowie die Kosten hierfür zu.

Bei der vorstehend beschriebenen Vorrichtung ist ein Tisch, der mittels den linearen Lagern zur Ausführung einer hin- und hergehenden Bewegung gelagert ist, am beweglichen Teil **100** vorgesehen, und die hin- und hergehende Bewegung des beweglichen Teils **100** wird durch die Drehbewegung der Kugelumlaufspindelwelle **102** bewirkt und dann von dem beweglichen Teil auf den Tisch übertragen. Bei dieser Vorrichtung ist ein Nachteil darin zu sehen, daß zeitraubende Arbeiten zur Einstellung der Parallelität zwischen den Führungsflächen der linearen Lager, an denen der Tisch festgelegt ist, und der Kugelumlaufspindelwelle **102** erforderlich sind. Genauer gesagt sollte die Einstellung der Parallelität zwischen den Führungsflächen der linearen Lager und der Kugelumlaufspindelwelle **102** unter Verwendung eines Zeigers vorgenommen werden, welche auf die äußere Umfangsfläche der Kugelumlaufspindel **102** aufgebracht wird, wodurch die Einstellung erschwert wird. Ferner ist es bei dem in **Fig.** 24 gezeigten Stand der Technik zusätzlich zu der Einstellung der Parallelität zwischen den Führungsschienen **101** und der Kugelumlaufspindelwelle **102** erforderlich, die Parallelität zwischen der Kugelumlaufspindelwelle **102** und den Führungsflächen an einer Tischseite einzustellen, wodurch die Arbeiten äußerst schwierig werden.

Die Erfindung zielt daher darauf ab, eine Kugelumlaufspindel-Führungseinheit bereitzustellen, bei welcher die vorstehend genannten Schwierigkeiten überwunden werden und bei der eine Vorspannung aufgebracht werden kann, ohne daß eine Geradlinigkeit der Kugelumlaufspindelwelle beeinträchtigt wird.

Ferner zielt die Erfindung darauf ab, eine Kugelumlaufspindel-Führungseinheit und einen Fördertisch unter Einsatz derselben bereitzustellen, wobei ein Tisch von einem linearen Lager getragen wird, welches an der Kugelumlaufspindel-Führungseinheit vorgesehen ist, um einen Fördertisch zu bilden, und wobei die Parallelität zwischen einer Führungsfläche eines linearen Lagers und einer Kugelumlaufspindelwelle sich auf einfache Weise einstellen läßt.

Hierzu wird nach der Erfindung eine Kugelumlaufspindel-Führungseinheit bereitgestellt, welche folgendes aufweist: eine Führungsschiene, welche von einem U-Stahlmaterial mit einer Ausnehmung gebildet wird; ein bewegliches Teil, welches passend zwischen den Seitenflächen der Ausnehmung und den dazwischenliegenden Kugeln angeordnet ist und das längs einer Längsrichtung der Führungsschiene beweglich ist; eine Kugelumlaufspindelwelle, die drehbeweglich mittels der Führungsschiene gelagert und über eine Gewindeverbindung in dem beweglichen Teil zur Ausführung einer hin- und hergehenden Bewegung des beweglichen Teils längs der Führungsschiene verbunden ist; und eine Vorspanneinrichtung zum Aufbringen einer axialen Zugbelastung auf einen Teil der Kugelumlaufspindelwelle zwischen den Lagerteilen, die an den gegenüberliegenden Enden der Führungsschiene vorgesehen sind.

Da bei der Kugelumlaufspindel-Führungseinheit mit dem vorstehend genannten Aufbau die Führungsschiene von einem U-Stahlmaterial mit einer Ausnehmung gebildet wird, liegt der Flächenschwerpunkt der Schiene in der Nähe der Ausnehmung, und die Kugelumlaufspindelwelle, welche mit dem beweglichen Teil zusammenarbeitet, liegt ebenfalls in der Nähe der Ausnehmung, so daß der Flächenschwerpunkt der Führungsschiene in der Nähe der Achse der Kugelumlaufspindelwelle liegt. Wenn daher die Vorspanneinrichtung eine Zugbelastung auf die Kugelumlaufspindelwelle aufbringt, wirkt eine Reaktionskraft als eine Druckbelastung an einer Stelle in der Nähe des Flächenschwerpunkts der Führungsschiene, so daß ein auf die Führungsschiene wirkendes Biegemoment klein ist. Daher läßt sich die Geradlinigkeit der Führungsschiene aufrecht erhalten, und die Vorschubgenauigkeit des beweglichen Teils läßt sich erhöhen.

Insbesondere wenn die Achse der Kugelumlaufspindelwelle im wesentlichen mit dem Flächenschwerpunkt der Führungsschiene übereinstimmt, bewirkt die auf die Kugelumlaufspindelwelle aufgebrachte Vorspannung kein Biegemoment in der Führungsschiene, und somit läßt sich die Geradlinigkeit der Führungsschiene perfekt einhalten.

Da das U-Stahlmaterial selbst, welches die Führungsschiene bildet, eine hohe Steifigkeit gegenüber einer Biegung in Folge ihrer Gestalt hat, ist es nicht erforderlich, eine Dicke der Führungsschiene zur Erhöhung der Steifigkeit zu vergrößern, wie dies bisher beim Stand der Technik vorgenommen wurde, so daß die Abmessungen und das Gewicht der Führungsschiene herabgesetzt werden können.

Selbst wenn die Kugelumlaufspindelwelle beschleunigt wird, wirkt eine Reaktion durch die Beschleunigung der Kugelumlaufspindelwelle nicht auf den Tisch, welcher dem beweglichen Teil zugeordnet ist, da das bewegliche Teil von der Führungsschiene getragen wird, welche die hohe Steifigkeit hat. Daher läßt sich eine genaue Bewegung des Tisches sicherstellen.

Ein Fördertisch kann eine solche Auslegung haben, daß das bewegliche Teil der Kugelumlaufspindel-Führungseinheit an einem Tisch angebracht ist, welcher mittels eines linearen Lagers gelagert ist und der sich auf einem Bett hin- und hergehend bewegen kann, wobei die Führungsschiene am Bett fest vorgesehen ist, und der Tisch in Richtung nach vorne und nach hinten um eine Größe entsprechend einer Drehgröße der Kugelumlaufspindelwelle bewegt werden. Bei dieser Auslegungsform kann die Führungsschiene vorzugsweise an ihren unteren und seitlichen Flächen mit Bezugsflächen versehen sein, welche zur Einstellung der Parallelität zwischen der Führungsschiene und der Achse der Kugelumlaufspindelwelle dienen.

Gemäß der voranstehend beschriebenen Auslegungsform läßt sich die Parallelität zwischen der Führungsschiene und der Achse der Kugelumlaufspindelwelle im voraus unter Verwendung der Bezugsfläche einstellen, die auf der Seitenfläche der Führungsschiene ausgebildet ist. Daher läßt sich die Parallelität zwischen der Achse der Kugelumlaufspindelwelle und der Führungsfläche des linearen Lagers lediglich dadurch einhalten, daß die Parallelität zwischen der Bezugsfläche, die an der Führungsschiene vorgesehen ist, und der Führungsfläche des linearen Lagers eingestellt wird, wodurch sich die Montage und der Zusammenbau des Tisches vereinfachen.

Weitere Einzelheiten, Merkmale und Vorteile der Erfindung ergeben sich aus der nachstehenden Beschreibung von bevorzugten Ausführungsformen unter Bezugnahme auf die beigefügte Zeichnung. Darin zeigt:

Die Erfindung wird nachstehend anhand von bevorzugten Ausführungsformen unter Bezugnahme auf die Zeichnung näher erläutert. In den **Fig.** 1 bis 22 wird eine Kugelumlaufspindel-Führungseinheit gemäß einer bevorzugten Ausführungsform nach der Erfindung gezeigt. Mit **1** ist allgemein eine Kugelumlaufspindel-Führungseinheit bezeichnet, welche im wesentlichen von einer Führungsschiene **2**, einem beweglichen Teil **3**, welches beweglich mit Hilfe der Schiene **2** gelagert ist, einer Kugelumlaufspindelwelle **7**, welche in Gewindeeingriff in dem beweglichen Teil **3** ist, einem Paar von Lagerteilen **410** und **420** zur Lagerung der Kugelumlaufspindelwelle **7**, einem Motor **18** zum Antreiben der Kugelumlaufspindelwelle **7** und einer Vorspanneinrichtung **50** gebildet wird, welche eine Zugvorspannung auf die Kugelumlaufspindelwelle **7** aufbringt.

Die Führungsschiene **2** wird von einem U-Stahlmaterial mit einem U-förmigen Querschnitt gebildet, welcher eine konkave Ausnehmung **21** hat und eine Bodenwand **23**, welche einen Grund einer Ausnehmung **21** bildet, und Seitenwände **22** umfaßt, die senkrecht von den gegenüberliegenden Seiten der Bodenwand **23** wegverlaufen.

Das bewegliche Teil **3** ist zwischen den inneren Seitenflächen **22a** der Ausnehmung **21** in der Führungsschiene **2**, d. h. zwischen den beiden Seitenwänden **22**, gehalten und gelagert. Das bewegliche Teil **3** ist nahezu über die gesamte Höhe in die Ausnehmung **21** eingesetzt und hat eine obere Fläche, welche geringfügig über die oberen Flächen der Seitenwände **22** vorsteht.

Die Seitenflächen der Ausnehmung **21** in der Führungsschiene **2** weisen zu den rechten und linken Flächen des beweglichen Teils **3** jeweils. Jede dieser rechten und linken Seitenflächen ist mit zwei Kugelwälzflächen **4a** und **4b** oder **5a** und **5b** versehen, auf welchen Wälzkörper, d. h. Kugeln **6**, bei der Ausführung einer Abwälzbewegung geführt sind.

Die Kugelwälzflächen **4a**, **4b**, **5a** und **5b**, welche in der Führungsschiene **2** vorgesehen sind, sind insgesamt mit einer Anzahl von vier vorhanden, und sie liegen an den Ecken der breiten Ausnehmungen **22**b, welche in den inneren Seitenflächen **22**a der Seitenwände **22** ausgebildet sind.

Das bewegliche Teil 3 wird von einem beweglichen Teilkörper **31** und Endplatten **32** gebildet, welche an gegenüberliegenden Endflächen des Körpers **31** befestigt sind. Der bewegliche Teilkörper **31** ist an den gegenüberliegenden Seiten insgesamt mit vier ausgenommenen Kugelwälzflächen 5a, 5b, 5c und 5d versehen, welche den Kugelwälzflächen **4**a, **4**b, **4**c und **4**d der Führungsschiene **2** jeweils zugeordnet sind. Eine große Anzahl von Kugeln **6** sind drehbeweglich zwischen den gegenüberliegenden Kugelwälzflächen **4**a und **5**a, **4**b und **5**b, **4**c und **5**c, **4**d und **5**d angeordnet.

Gegenüberliegende Enden **71** und **72** der Kugelumlaufspindelwelle **7** sind drehbeweglich mittels ersten und zweiten Lagerteilen **410** und **420** gelagert, welche an gegenüberliegenden Enden der Führungsschiene **2** angeordnet sind.

Der erste Lagerabschnitt **410** umfaßt eine erste Endplatte **412**, welche fest mit einer Endfläche der Führungsschiene **2** mit Hilfe von Schrauben **411** verbunden ist, und ein erstes Kugellager **415**, welches einen doppelreihigen Winkelkontakt hat und in eine axiale Öffnung **414** passend eingesetzt ist, welche an einem Mittelteil der ersten Endplatte **412** ausgebildet ist. Ein erstes axiales Ende **71** der Kugelumlaufspindelwelle **7** ist passend in die axiale Öffnung **414** der ersten Endplatte **412** mittels des ersten Kugellagers **415** eingesetzt.

Der zweite Lagerabschnitt **412** wird von einem Gehäuse **423** gebildet, welches eine zweite Endplatte **422** hat, welche fest mit der anderen Endfläche der Führungsschiene **2** mit Hilfe von Schrauben **421** verbunden ist, und einem zweiten Kugellager **425**, welches einen doppelreihigen Winkelkontakt hat und passend in einer axialen Öffnung **424** eingesetzt ist, die an einem Mittelteil der zweiten Endplatte **422** ausgebildet ist. Ein zweites Ende **72** der Kugelumlaufspindelwelle **7** ist in einer Axialöffnung **424** der zweiten Endplatte **422** unter Zwischenlage eines zweiten Lagers **425** eingesetzt.

Das zweite axiale Ende **72** ist mit einem Verbindungswellenabschnitt **723**, einem Gewindeabschnitt **722** und einem Lagerabschnitt **721** versehen, welcher axial fluchtgerecht in dieser Anordnung ausgehend von dem Ende des Endabschnitts **72** angeordnet ist. Der Lagerabschnitt **721** ist passend in dem zweiten Kugellager **425** angeordnet, und der Verbindungswellenabschnitt **723** und der Gewindeabschnitt **722** gehen durch die axiale Öffnung **424** und erstrecken sich in Richtung auf einen Motor **18**. Die Verbindungswelle **723** ist mit einer Antriebswelle **181** des Motors **18** über eine Kupplung **19** verbunden.

Der Motor **18** ist fest mit einer dritten Endplatte **426** verbunden, welche am Gehäuse **423** ausgebildet ist, und zwar mittels Schrauben **182**. Die Antriebswelle **181** ist koaxial zu der Kugelumlaufspindelwelle **7**. Die dritte Endplatte ist der zweiten Endplatte **422** unter Einhaltung eines vorbestimmten axialen Zwischenraumes zugewandt. Der Zwischenraum zwischen der zweiten und dritten Endplatte **422** und **426** wird genutzt, um die Kupplung **19** aufzunehmen. Die Kupplung **19** ist mit Öffnungen **191** und **192** versehen. Die Antriebswelle **181** des Motors **18** und der Verbindungswellenabschnitt **723** der Kugelumlaufspindelwelle **7** sind die Öffnungen **191** und **192** jeweils eingesetzt und sie sind fest mit der Kupplung mit Hilfe von Schrauben **193** und **194** verbunden. Eine obere Öffnung des Gehäuses **423** des Motors **18** ist mit oberen und unteren Stützabdeckungen **427** und **428** abgedeckt. Eine Verbindungseinrichtung **429** zur Herstellung einer elektrischen Verbindung mit dem Motor **18** ist an der unteren Stützabdeckung **428** angebracht.

Die Positionen der ersten Endplatte **413** des ersten Lagerabschnitts **410** und der zweiten Endplatte **422** des zweiten Lagerabschnitts **420** lassen sich in einer Richtung senkrecht zu der Kugelumlaufspindelwelle **7** einstellen. Die Seitenfläche der Führungsschiene **2** bildet eine Bezugsfläche A für die Einstellung der Parallelität zwischen einer Achse der Kugelumlaufspindelwelle **7** und der Führungsschiene. Die Positionseinstellung der ersten Endplatte **413** läßt sich unter Verwendung eines kleinen Spiels zwischen den Schrauben **411** und den Schrauböffnungen **411**a vornehmen. In ähnlicher Weise erfolgt die Positionseinstellung der zweiten Endplatte **422** unter Verwendung eines geringfügigen Spieles zwischen den Schrauben **421** und den Schrauböffnungen **421**a.

Eine Vorspanneinrichtung **50** wird von ersten und zweiten Lagerhaltermuttern **511** und **512** gebildet, welche mit den Kugellagern **415** und **425** in den ersten und zweiten Lagerabschnitten **71** und **72** jeweils zusammenarbeiten. Bei der dargestellten bevorzugten Ausführungsform ist die Lagerhaltermutter **512** des zweiten Lagerabschnittes **420** zu Beginn so angezogen, daß der Motor **18** und weitere Teile angeordnet sind und abschließend wird die erste Lagerhaltermutter **511** des ersten Lagerabschnittes **410** unabhängig von dem Motor und weiteren Teilen festgelegt, so daß eine Zugbelastung auf die Kugelumlaufspindelwelle **7** aufgebracht wird.

Das zweite Kugellager **425** ist in die Axialöffnung **424** von einem offenen Ende her eingesetzt, welches der Führungsschiene **2** zugewandt ist. Ein Teil der axialen Öffnung **424** in der Nähe des Motors **18** hat einen Durchmesser, welcher kleiner als ein Außendurchmesser des zweiten Kugellagers **425** ist, so daß die axiale Öffnung **425** mit einem stufenförmig abgesetzten Abschnitt versehen ist, gegen welchen das zweite Lager **425** zur Anlage kommt und der Lagerhalter **522** ist in die axiale Öffnung **424** geschraubt.

Die ersten und zweiten Bundteile **532** und **542** sind passend um den Lagerabschnitt **721** des zweiten Lagerabschnittes **72** angeordnet, wobei das zweite Kugellager **425** dazwischenliegt. Das erste Bundteil **531** ist zwischen einer Endfläche des zweiten Kugellagers **425** in der Nähe der Führungsschiene **2** und einem stufenförmig abgesetzten Abschnitt **73** angeordnet, welcher in einem Basisende des Lagerabschnittes **721** der Kugelumlaufspindelwelle **7** ausgebildet ist. Das zweite Bundteil **54** ist zwischen der weiteren Endfläche des zweiten Kugellagers **425** und der Lagerhaltermutter **512** angeordnet.

Das erste Kugellager **415** ist in die axiale Öffnung **414** ausgehend von einer endseitigen Öffnung eingesetzt, welche der Führungsschiene **2** zugewandt ist. Ein Teil der axialen Öffnung **414**, welcher von dem Motor **18** entfernt liegt, hat einen Durchmesser, welcher kleiner als ein Außendurchmesser des ersten Kugellagers **415** ist, so daß die axiale Öffnung **425** mit einem stufenförmig abgesetzten Abschnitt **4141** versehen ist, gegen welchen das erste Lager **415** zur Anlage kommt, wenn der Lagerhalter **521** in die axiale Öffnung **414** geschraubt ist.

Die ersten und zweiten Bundteile **531** und **541** sind passend um den Lagerabschnitt **711** des ersten Lagerabschnittes **71** angeordnet, wobei das erste Kugellager **415** dazwischenliegt. Das erste Bundteil **531** ist zwischen einer Endfläche des ersten Kugellagers **415** in der Nähe der Führungsschiene 2 und einem stufenförmig abgesetzten Abschnitt **74** angeordnet, der an einem Basisende des Lagerabschnittes der Kugelumlaufspindelwelle **7** ausgebildet ist. Das zweite Bundteil **541** ist zwischen dem ersten Kugellager **415** und der ersten Lagerhaltermutter **511** angeordnet.

Die Kugelumlaufspindelwelle **7** befindet sich zu Beginn in einem freien Zustand während eines Montagevorganges, wie dies in **Fig.** 1 gezeigt ist. Das erste Kugellager **415** und die stufenförmig abgesetzte Fläche **74** der Kugelumlaufspindelwelle **7** liegen derart, daß ein Spalt g entsprechend einer Größe einer Vorspannung vorhanden ist, und anschließend wird die Lagerhaltermutter **511** angezogen, um die Kugelumlaufspindelwelle **7** um eine Größe zu expandieren, welche dem Spalt g entspricht, um eine Zugbelastung bzw. Zugkraft F aufzubringen. Daher läßt sich nur durch das Festziehen der Lagerhaltermutter **511** die Zugbelastung auf eine geeignete Größe einstellen.

Da bei der dargestellten bevorzugten Ausführungsform ein Flächenschwerpunkt des in etwa U-förmig ausgelegten Querschnitts der Führungsschiene **2** mit einer Achse O der Kugelumlaufspindelwelle **7** übereinstimmt, bewirkt eine Druckbelastung, die man als eine Reaktionskraft der Vorspannung der Kugelumlaufspindelwelle **7** erhält, nicht als eine abweichende Belastung gegenüber der Führungsschiene **2**.

Im Hinblick auf die Auslegung des beweglichen Teils **3** ist der bewegliche Teilkörper in seiner Mitte mit einer sie durchsetzende Kugelumlaufspindel **8** versehen, welche mit einer Vorschubspindel, d. h. einer Kugelumlaufspindelwelle **7**, zusammenarbeitet. Die Kugelumlaufspindelöffnung **8** liegt auf einer Linie, die im wesentlichen die Mitten der überbrückenden Teile zwischen der oberen und unteren Kugelwälzfläche **5a** und **5b** verbindet. Bei dieser bevorzugten Ausführungsform hat die Kugelumlaufspindelöffnung einen Durchmesser ähnlich den Überbrückungsteilen zwischen den Kugelwälzflächen **5a, 5b, 5c** und **5d**.

Zwischen der Kugelumlaufspindelöffnung **8** und den Seitenflächen des beweglichen Teilkörpers **31** sind vier Kugelaustrittsöffnungen **6a, 6b, 6c** und **6d** für den Austritt der Kugeln aus den Belastungsbereichen versehen. Die Kugelöffnungen **6a, 6b, 6c** und **6d** sind den Kugelwälzflächen **5a, 5b, 5c** und **5d** zugeordnet, und zwei derselben sind in einem Abstand von den anderen beiden Öffnung angeordnet, wobei die Kugelumlaufspindelöffnung **8** dazwischenliegt. Die Kugelumlaufspindelöffnungen **6a, 6b, 6c** und **6d** liegen auf horizontalen Linien, die durch die Kugelwälzflächen **5a, 5b, 5c** und **5d** jeweils gehen. Eine Vorbelastung wird auf jede Kugel **6** aufgebracht. Diese Vorbelastung erhält man dadurch, daß die Kugeln **6** in einem komprimierten Zustand in dem jeweiligen Zwischenraum passend eingesetzt sind, welche von vier Sätzen von wechselseitig zugewandten Kugelwälzflächen **4a** und **5a, 4b** und **5b, 4c** und **5c** und **4d** und **5d** gebildet werden.

Zwischen den Kugelaustrittsöffnungen **6a, 6b, 6c** und **6d** und den Seitenflächen des beweglichen Teilkörpers **31** sind Bolzenöffnungen **9** zum Anbringen eines zu transportierenden Gegenstandes an dem beweglichen Teilkörper **31** vorgesehen.

Die Kugelumlaufspindelöffnung **8**, die durch die Mitte des beweglichen Teilkörpers **31** geht, hat eine Gewindeausnehmung in einem Bereich in jener Nähe, welche einer Hälfte eines Bereiches entspricht, an welcher eine Öffnung **33** vorgesehen ist, die den beweglichen Teilkörper **31** durchsetzt. Ein Rücklaufrohr **10** ist mit der Öffnung **8** verbunden, um einen Kugelrücklaufkanal zu bilden. Das Rücklaufrohr **10** wird mittels eines Halters **10a** gehalten. Die Vorbelastung wirkt auch auf die Kugeln **6**, die zwischen der Kugelumlaufspindel **7** und der Kugelumlaufspindelöffnung **8** liegen, so daß ein Rattern verhindert wird, welches in axialer Richtung der Kugelumlaufspindelwelle auftreten könnte. Um die Vorbelastung aufzubringen, kann eine Differenz zwischen der Steigung der Gewindeausnehmung in der Kugelumlaufspindelöffnung **8** unter der Steigung des Gewindes der Kugelumlaufspindelwelle **7** oder mittels anderen Auslegungsformen erreicht werden.

Die Kugeln **6**, die zwischen den Seitenflächen des beweglichen Teilkörpers **31** und den inneren Seitenflächen der Führungsschiene **2** angeordnet sind, berühren die zugeordneten Kugelwälzflächen **4a** und **5a, 4b** und **5b, 4c** und **5c** oder **4d** und **5d** in Kontaktrichtungen, welche derart bestimmt sind, daß man nach außen divergierend verlaufende Anordnungen erhält, und welche insbesondere derart bestimmt sind, daß imaginäre Linien La, Lb, Lc und Ld, die durch die Kontaktpunkte zwischen den zugeordneten Kugeln **6** und den zugeordneten Kugelwälzflächen **4a** und **5a, 4b** und **5b, 4c** und **5c** und **4d** und **5d** und durch die Kugeln gehen, einen konvergierenden Verlauf zu der Mitte der Kugelumlaufspindelwelle **7** bezüglich einer horizontalen Linie H haben können, die durch die Mitte der Kugelumlaufspindelwelle **7** geht. Die Winkel zwischen den imaginären Linien La, Lb, Lc und Ld und der horizontalen Linie H können sich gegebenenfalls etwa auf 45° belaufen.

Die Endplatte **32** ist ein viereckförmiges Teil, welches eine ähnliche Gestalt wie die Endfläche des beweglichen Teilkörpers **31** hat, und sie ist in ihrer Mitte mit einer Durchgangsöffnung **32a** zum Einführen der Kugelumlaufspindelwelle **7** versehen. Bolzenöffnungen **32b** sind in Querrichtung an den gegenüberliegenden Seiten der Einschuböffnung **32a** zum Fixieren des beweglichen Teilkörpers **31** angeordnet.

Eine Befestigungsfläche der Endplatte **32** für den beweglichen Teilkörper **31** ist mit vier Rücklaufkanälen **11a, 11b, 11c** und **11d** zum Rückführen der Kugeln **6** versehen, welche im Belastungsbereich zwischen dem beweglichen Teilkörper **31** und der Führungsschiene **2** angeordnet sind, um dieselben zu den Kugelaustrittsöffnungen **6a, 6b, 6c** und **6d** zu leiten. Der Rücklaufkanal **11a** wird von einer ausgenommenen Aussparung **12** mit einem halbkreisförmigen Querschnitt in der Endplatte **32** gebildet, und ein Rücklaufstück **13**, welches halbkreisförmig ausgebildet ist, ist konzentrisch bezüglich der Ausnehmung **12** angeordnet. Das Rücklaufstück **13** ist an seinem Außenumfang mit einer bogenförmigen Ausnehmung **13a** versehen, welche komplementär hinsichtlich ihrer Gestalt zu dem äußeren Umfang der Kugel **6** ausgelegt ist, so daß die bogenförmige Ausnehmung **13a** und die ausgenommene Aussparung **32a** in der Endplatte **32** die rohrförmigen Rücklaufkanäle **11a, 11b, 11c** und **11d** mit einer halbkreisförmigen Gestalt bilden. Es ist erwünscht, daß eine Krümmung jedes Rücklaufkanales **11a, 11b, 11c** und **11d** nahezu das Dreifache des Durchmessers der Kugel oder größer beträgt.

Kugelhalter **14** zum Halten der Kugeln **6** sind zwischen den Seitenflächen des beweglichen Teilkörpers **31** und den inneren Seitenflächen der Führungsschiene **2** angeordnet. Jeder Kugelhalter **14** ist ein Plattenteil, welches in einer Ausnehmung **22b** aufgenommen ist, in einer inneren Seitenfläche der jeweiligen Seitenwand **22** der Führungsschiene **2** ausgebildet ist. Der Halter **14** wird an einer seiner Fläche gegen die Seitenfläche des beweglichen Teilkörpers **31** gedrückt und mit Hilfe von Schrauben **15** festgelegt.

Jeder Halter **14** ist an seinen gegenüberliegenden Seitenrändern mit Ausnehmungen **16** mit bogenförmigem Querschnitt versehen, welche entsprechend der Krümmung der Kugel **6** gekrümmt sind, so daß die Kugeln **6** in den oberen und unteren Reihen durch die bogenförmigen Ausnehmungen **16** gehalten sind ohne von dem beweglichen Teilkörper **31** freizukommen.

Die Halter **14** sind in Räumen zwischen den oberen und unteren Kugelwälzflächen angeordnet, welche Brückenteile haben, die bis zu einem Größenwert größer werden und sie sind in diesen Räumen angeordnet. Somit haben die Halter **14** Breitenabmessungen, welche nahezu gleich den Gesamtbreitenabmessungen der Überbrückungsteile sind und die bogenförmigen Ausnehmungen **16** an den gegenüberliegenden Seitenrändern liegen in der Nähe der Kugeln **6**. Die Kugeln **6** in den Belastungsbereichen führen eine Abwälzbewegung ohne eine Berührung dieser bogenförmigen Ausnehmungen **16** aus.

Die Kugelumlaufspindelwelle **7**, welche in der Kugelumlaufspindelöffnung **8** im beweglichen Teil **3** in Gewindeeingriff ist, ist drehbeweglich an einem Ende mittels eines Lagerabschnittes **17** gelagert, welcher an einem Ende der Führungsschiene **2** vorgesehen ist, und sie ist antriebsverbunden am anderen Ende über die Kupplungen **19** mit dem Motor **18**, welcher am anderen Ende der Führungsschiene **2** angebracht ist.

In den **Fig.** 3 bis 5 ist mit der Bezugsziffer **80** eine Befestigungsplatte zum Anbringen eines Sensors (nicht gezeigt) bezeichnet. Die Platte **80** kann fest an einer beliebigen Position auf einer Schiene **81** angebracht werden, die auf und längs der äußeren Seitenfläche der Führungsschiene **2** angeordnet ist. Der Sensor ist an der Sensorbefestigungsplatte **80** über ein Befestigungsstück **82** angebracht. Wenn eine Deckplatte **83**, die am beweglichen Teil **3** angebracht ist, den Sensor überfährt, wird festgestellt, daß das bewegliche Teil **3** in einer vorbestimmten Position (beispielsweise einer Anfangsposition) ist.

Eine Bezugsziffer **84** bezeichnet einen ringförmigen, ersten Anschlag, welcher passend in der Axialöffnung **413** in dem ersten Lagerabschnitt **71** angeordnet ist, und mit einer Bezugsziffer **85** wird ein zweiter Anschlag bezeichnet, welcher im zweiten Lagerabschnitt **72** vorgesehen ist. Diese Anschläge berühren die Endflächen des beweglichen Teils **3** zur Begrenzung eines Bewegungsbereiches des beweglichen Teils **3**.

Wenn bei der Kugelumlaufspindel-Führungseinheit mit dem vorstehend beschriebenen Aufbau der Motor **18** drehangetrieben wird, wird die Kugelumlaufspindelwelle **7** gedreht und die Drehbewegung derselben wird über die Kugelumlaufspindelöffnung **8** auf das bewegliche Teil **3** übertragen, so daß das bewegliche Teil **3** längs der Führungsschiene **2** eine hin- und hergehende lineare Bewegung ausführt. Bei dieser Arbeitsweise ist die Zugbelastung F auf der Kugelumlaufspindel **7** durch die ersten und zweiten Lagerhaltermuttern **511** und **512** zum Ausgleich der Wärmedehnung der Kugelumlaufspindelwelle **7** aufgebracht, welche bei einer Hochgeschwindigkeitsdrehbewegung auftreten kann. Als eine Reaktion hierauf wirkt eine Druckbelastung auf die Führungsschiene **2** über der ersten und zweiten Endplatte **412** und **422** des ersten und zweiten Lagerabschnittes **410** und **420** ein. Die Führungsschiene **2** jedoch wird von einem U-förmigen U-Stahlmaterial gebildet, welches eine höhere Steifigkeit gegenüber Biegebelastungen hat, so daß die Seitenwände **22** als Versteifungsträger wirken und eine Verformung, wie ein Durchbiegen, verhindert werden kann. Da der Flächenschwerpunkt der Führungsschiene **2** und die Achse O der Kugelumlaufspindel **7** miteinander zusammenfallen verlagert sich die Druckbelastung, welche auf die Führungsschiene **2** wirkt, nicht bezüglich der Achse der Kugelumlaufspindelwelle, so daß ein unnötiges Biegemoment nicht auf die Führungsschiene **2** einwirkt.

Da entsprechend der vorstehenden Beschreibung das Biegemoment nicht auf die Führungsschiene **2** einwirkt, wird die Kugelumlaufspindelwelle **7** in einem geraden Zustand gehalten. Diese Tatsache sowie die Tatsache, daß die gegenüberliegenden Seiten des beweglichen Teils **3** mit Hilfe den Kugeln **6** abgestützt und gelagert sind, dienen dazu, daß ein Verwerfen der Kugelumlaufspindelwelle **7** verhindert wird, so daß man eine genaue Steuerung der Förderbewegung erhält.

Bei dieser bevorzugten Ausführungsform sind die Kontaktrichtungen der Kugeln **6**, die zwischen dem Tisch **3** und der Führungsschiene **2** angeordnet sind, derart geneigt, daß sie einen nach außen divergierenden Verlauf bezüglich der horizontalen Linie H haben, welche durch die Mitte der Kugelumlaufspindelwelle geht, so daß die vertikalen und horizontalen Belastungen, nämlich auf das bewegliche Teil **3** wirken, effektiv von den Kugeln **6** aufgenommen werden. Wenn insbesondere der Neigungswinkel sich auf etwa 45° beläuft, können die Belastungen in den vier Richtungen, d. h. vertikale und horizontale Richtungen, in gleicher Weise aufgenommen werden. Ferner kann in wirksamer Weise verhindert werden, daß die auf die Kugeln **6** einwirkende Vorbelastung ein Rattern des beweglichen Teils **3** verursacht.

Da entsprechend der voranstehenden Beschreibung das Rattern des beweglichen Teils **3** verhindert werden kann, ist es unmöglich, Vibrationen zu verhindern, welche während den Fördervorgängen auftreten können, und insbesondere während den Anfahr- und Anhaltevorgängen auftreten können, d. h. Neigungsbewegungen (Schwingungen des beweglichen Teils **3**, welche um eine Achse senkrecht zur Zeichenebene in **Fig.** 3 erregt werden), eine Wälzbewegung (eine Schwingung des beweglichen Teils **3**, welches um eine Achse senkrecht zur Zeichenebene in **Fig.** 5 erregt wird) und eine Seitenbewegung (eine Schwingung des beweglichen Teils **3**, welche um eine Achse senkrecht zu der Zeichenebene von **Fig.** 4 erregt wird), so daß das bewegliche Teil **3** gleichförmig bewegt bzw. gefördert werden kann. Da das Überbrückungsteil zwischen den oberen und unteren Kugelwälzflächen soweit wie möglich vergrößert wird, hat die Auslegung eine hohe Festigkeit bezüglich eines Belastungsmomentes, welches derart wirkt, daß das bewegliche Teil **3** um die Förderachse gedreht wird.

Es ist noch zu erwähnen, daß der Querschnitt der Führungsschiene **2** nicht auf eine U-förmige Gestalt gemäß der bevorzugten Ausführungsform beschränkt ist, sondern wie es in **Fig.** 21 gezeigt ist, kann eine mit einem Flansch versehene U-förmige Gestalt vorgesehen sein, bei der die Seitenwände **22** an ihren Enden mit horizontal vorspringenden Flanschen **24** versehen sind. Ferner kann nach **Fig.** 22 eine U-förmige Gestalt vorgesehen sein, welche mit Lippen **25** versehen ist, die an den oberen Wänden der Seitenwände **22** ausgebildet sind und welche nach innen verlaufen, um die Öffnung der Ausnehmung **21** zu verkleinern.

Wenn man die U-förmige Gestalt vorsieht, welche die

Flansche oder die Lippen hat, läßt sich die Steifigkeit der Führungsschiene **2** weiter erhöhen, so daß die Vorspannung effektiver auf die Kugelumlaufspindelwelle **7** aufgebracht werden kann. Bei der Auslegung mit einer U-förmigen Gestalt, welche Lippen hat, ist das bewegliche Teil **3** in der Führungsschiene **2** aufgenommen, und das bewegliche Teil **3** ist an seiner oberen Fläche mit einem stufenförmig abgesetzten Vorsprung **33** versehen, welcher zwischen den Lippen **25** vorsteht. Der stufenförmig abgesetzte Vorsprung **33** bildet eine Befestigungsfläche **34**.

Fig. 23 zeigt einen Fördertisch, welcher mit der Kugelumlaufspindel-Führungseinheit **1** mit der vorstehend beschriebenen bevorzugten Ausführungsform ausgestattet ist. Ein stationäres Bett **1000** lagert einen Tisch **1002** mittels eines Paars von rechten und linken linearen Lagern **1001**, um eine hin- und hergehende Bewegung desselben zu ermöglichen. Die linearen Lager **1001** können von unterschiedlichen, an sich bekannten Führungseinrichtungen gebildet werden. Jedes lineare Lager wird von einem Schienenbett **1003** und einem Lagerkörper **1005** gebildet, welcher gleitbeweglich längs der Längsrichtung des Schienenbetts **1003** über die Wälzteile **1004** geführt ist.

Die Kugelumlaufspindel-Führungseinheit **1** ist zwischen den beiden linearen Lagern **1001** angeordnet, und die Führungsschiene **2** der Kugelumlaufspindel-Führungseinheit **1** ist fest mit dem stationären Bett **1000** verbunden. Das bewegliche Teil **3** ist fest mit dem Tisch **1002** verbunden. Die Parallelität zwischen der Achse der Kugelumlaufspindelwelle **7** und eine Führungsfläche des linearen Lagers **1001** wird unter Nutzung der Bezugsebene A eingestellt, welche auf der unteren Fläche und den Seitenflächen der Führungsschiene **2** ausgebildet ist.

Bei der vorstehend beschriebenen Kugelumlaufspindel-Führungseinheit **1** kann vor dem Montageschritt zum Festlegen der Führungsschiene **2** an dem Bett **1000** die Parallelität zwischen der Achse der Kugelumlaufspindelwelle **7** und der Führungsschiene **2** auf der Basis der Bezugsfläche A eingestellt werden. Daher kann die Einstellung der Parallelität zwischen der Achse der Kugelumlaufspindelwelle **7** und der Führungsfläche des linearen Lagers **1001** nur dann abgeschlossen werden, wenn die Einstellung der Parallelität zwischen dem Schienenbett **1003** des linearen Lagers und der Bezugsfläche A erfolgt ist, welche auf der Führungsschiene **2** ausgebildet ist. Selbst wenn bei dem Fördertisch die Kugelumlaufspindelwelle **7** eine Versetzung hat, wird der Einfluß durch diese Versetzung nicht auf den Tisch **102** übertragen, welcher dem beweglichen Teil **3** zugeordnet ist, da das bewegliche Teil **3** durch die Führungsschiene **2** abgestützt gelagert ist. Somit kann man eine genaue Bewegung sicherstellen.

Patentansprüche

1. Kugelumfaufspindel-Führungseinheit (**1**), **gekennzeichnet durch** eine Führungsschiene (**2**), welche aus einem U-Stangenmaterial hergestellt ist, welches eine Ausnehmung (**21**) hat,
ein bewegliches Teil (**3**), welches passend zwischen den Seitenflächen der Ausnehmung (**21**) unter Zwischenlage von Kugeln (**6**) angeordnet ist und längs einer Längsrichtung der Führungsschiene (**2**) beweglich ist,
eine Kugelumlaufspindelwelle (**7**), welche drehbeweglich durch die Führungsschiene (**2**) gelagert ist und in Gewindeeingriff mit dem beweglichen Teil (**3**) zur Ausführung einer hin- und hergehenden Bewegung des beweglichen Teils (**3**) längs der Führungsschiene (**2**) ist, und
eine Vorspanneinrichtung (**50**) zum Aufbringen einer axialen Zugbelastung (F) auf einen Teil der Kugelumlaufspindelwelle (**7**) zwischen den Lagerabschnitten (**71**, **72**), die an den gegenüberliegenden Enden der Führungsschiene (**2**) vorgesehen sind.
2. Kugelumlaufspindel-Führungseinheit nach Anspruch 1, dadurch gekennzeichnet, daß eine Achse (O) der Kugelumlaufspindelwelle (**7**) im wesentlichen mit einem Flächenschwerpunkt eines Querschnitts der Führungsschiene (**2**) übereinstimmt.
3. Kugelumlaufspindel-Führungseinheit nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß die Führungsschiene (**2**) an ihren unteren Flächen und Seitenflächen mit einer Bezugsebene (A) zur Einstellung der Parallelität zwischen der Führungsschiene (**2**) und der Kugelumlaufspindelwelle (**7**) versehen ist.
4. Fördertisch, welcher einen Tisch (**1002**) umfaßt, der mittels eines linearen Lagers (**1001**) gelagert ist, welches fest an einem Bett (**1000**) angebracht ist, um eine hin- und hergehende Bewegung auszuführen, dadurch gekennzeichnet, daß eine Antriebseinrichtung zum Bewegen des Tisches (**1002**) um einen beliebigen Weg in Vorwärts- und Rückwärtsrichtung vorgesehen ist, daß die Antriebseinrichtung eine Führungsschiene (**2**), die aus einem U-Stangenmaterial mit einer Ausnehmung (**21**) ausgebildet und fest mit dem Bett (**1000**) verbunden ist, ein bewegliches Teil (**3**), welches passend zwischen den Seitenflächen der Ausnehmung (**21**) unter Zwischenlage von Kugeln (**6**) angeordnet ist und längs einer Längsrichtung der Führungsschiene (**2**) beweglich ist, eine Kugelumlaufspindelwelle (**7**), die drehbeweglich durch die Führungsschiene (**2**) gelagert und in Gewindeeingriff in dem beweglichen Teil (**3**) zur Ausführung einer hin- und hergehenden Bewegung des beweglichen Teils (**3**) und des Tisches (**1002**) längs der Führungsschiene (**2**) ist, und eine Vorspanneinrichtung (**50**) zum Aufbringen einer axialen Zugbelastung auf einen Abschnitt der Kugelumlaufspindelwelle (**7**) zwischen den Lagerabschnitten (**71**, **72**) aufweist, welche an den gegenüberliegenden Enden der Führungsschiene (**2**) vorgesehen sind, wobei die Führungsschiene (**2**) an ihren unteren Flächen und Seitenflächen mit einer Bezugsebene (A) zur Einstellung der Parallelität zwischen der Führungsschiene (**2**) und der Kugelumlaufspindelwelle (**7**) versehen ist.
5. Kugelumlaufspindel-Führungseinheit nach Anspruch 4, dadurch gekennzeichnet, daß eine Achse (O) der Kugelumlaufspindelwelle (**7**) im wesentlichen mit einem Flächenschwerpunkt eines Querschnitts der Führungsschiene (**2**) übereinstimmt.
